Notes on Africa. — [Hutton, Travels in Africa; Adams, Remarks on the Countries extending from Cape Palmer to the River Congo; Monrad, Gemäldd der Künste von Guinea; Parliamentary Papers.]

GOODS. In actions for the non-delivery of goods, the plaintiff, if successful, may now have the same alternative judgment as in the action of assumpsit (S. 9); that is, either to have the goods themselves specifically delivered to him, or the value of them assessed by the jury. This most beneficial change in the law is made, and an appropriate writ of execution, to give effect to it, is inserted in the Magna Charta Law Amendment Act, 1855, 19 & 20 Vict. c. 97.

GOOLE. [Yorkshire.]

GOOSE-BRASS. [Gallium, S. I.]

GORGONIA, a genus of Animals belonging to the order Pneumatica, the modern name of the family Gorgonidea. It has the following generic characters:—Polypse-mass rooted, arboreous, consisting of a central axis backed with a polyporous crust; the axis homo, continuous, and it is of the same size as the crust when reduced; the crust when worn and slightly, when dried porous and friable; the orifice of the polype-cells more or less racemose. The species of Gorgonidea thus described are not numerous. Dr. Johnston enumerates four species as being found on the British coasts.

G. verrucosa, the Warty Sea-Fan, is somewhat fleshy, much and irregularly-branched, the branches cylindrical, flexuous, backed when dry with a white warty crust; segments of the cells unequal, oblong. This polype is abundant in the rocks of the southern coast of England. It lives in deep water.

G. pinnata, branched and pinnated, the branches compressed; polype-cells in regular rows on each margin, nearly cylindrical. The Warty Sea-Fan of Mr. Forbes was dredged by Mr. Forbes in the sound of Skye, where they found it attached to stones in 30 fathoms water.

G. placomus, irregularly branched, the branches disposed in a dichotomous order and a flatting form, cylindrical, with its short little mouths along both the margins. This is a rare species. It was found originally by its describer Mr. Dale, near Margate. It is of a violet colour when fresh. It is a doubtful native of our seas. G. fistulatum has been found on British coasts, but it has been undoubtedly accidental. (Johnston, British Zoophyta.)

GOTHITHE, a Mineral, to which also the name Lepidolite is given. It is a hydrousoxide of iron, differing from the brown iron-oxide by containing half as much water. The crystals are of a brown colour, and blood-red by transmitted light when sub-transparent. It has a hardness of 5, and its specific gravity 4 to 4.2. It is found with basaltic and andesitic rocks in Nassau, also in silica Turgite, from the Ural, seems to be identical. (Grainacée. [Grainacée.] The following list of British genera is from Buckingham's Manual British Botany:—

**Digitaria.**

*Alcyonea.* Schloehia. *Acorus.*

*Allypogon.* Descrip. *Aegiphila.*

*Cynodon.* Arundo. *Bromus.*

*Eryngium.* Leontodon. *Arctium.*

*Corynephora.* Echinocochloa. *Archerthemia.*

The family is very numerous. Pearson's *Synopsis* contains 812 species, 126th part of all the plants thereby enumerated. In the system of Rosier and Schulze here adopted, the arrangement of the order is more compact. The conclusion, would probably contain 40,000 in all, it may be assumed that the species form 22nd part of the whole. It is more than probable however that in future the number will increase in a larger ratio than the other phanerogamic plants, and this proportion will probably reach 1 in 4 to 16. Greater still will be their proportion to vegetation in general when the number of individuals is taken into account, for it
The tropical grasses acquire a much greater height, and occasionally assume the appearance of trees. Some species of **Bamboo**s are from 60 to 60 feet high.

The leaves of the tropical grasses are broader, and approach more in form to those of other families of plants. Of this the genus **Paspalum** affords many examples.

2. Separate sexes are more frequent in the tropical grasses. **Zea**, **Sorghum**, **Andropogon**, **Oryza**, **Achnatherum**, **Ileophila**, **Echinochloa**, and others all have separate sexes. In the northern temperate zones this condition never occurs in the torrid zone, and are there found in perfection, are monocious or polygamous. **Holcus** is perhaps the only extra-tropical genus with separate sexes.

4. The large grasses which are tall, and elegant.

6. The extra-tropical grasses on the contrary far surpass the tropical in respect of the number of individuals. That compact grassy turf, which especially in the colder parts of the temperate zones in spring and summer composeth the green meadows and fields, is almost entirely wanting in the torrid zone. The grasses there do not grow crowded together, but like other plants, more dispersed. Even in the northern parts of Europe the assimilation to the warmer regions in this respect is by no means inconsiderable.

4. A number of the tropical grasses, the Bamboo, **Buchnera Ruossaw**, **S. Tenerifer**, **Imperata arundinacea**, **Lepoglossus setus**, **Lycium aphyllum**, and the species of **Andropogon**, **Echinochloa**, &c., by separate sexes exhibit tropical qualities. The grasses are also less greasy, and meadow-swindom occur in the south than in the north of Europe. The generality are social plants.

The distribution of cultivated grasses is one of the most interesting of all subjects. It is determined not merely by climate, as in the case of wheat and maize, but also by the peculiarities of the people, and often on historical events. Within the northern polar circle agriculture is found only in a few places. In Siberia grain reaches at the utmost only to 60°, in the eastern parts scarcely above 50°, and in Kamtschatka the same. In all these regions, therefore, the bread-grain is unknown.

The polar limit of agriculture on the north-west coast of America appears to be somewhat higher, for in the more southern Russian possessions (57° to 58°) barley and rye come to maturity. Only in Europe, namely in Lapland, does the polar limit reach an unusually high latitude. Beyond this dried fish, and here and there potatoes, supply the place of grain.

The grains which extend farthest to the north in Europe are barley and oats. Those, which in the milder climates are not used for bread, afford to the inhabitants of the northern parts of Norway and Sweden, of a part of Siberia and Scotland, their chief vegetable nourishment. Rye is the grain which becomes associated with these. This is the prevalent grain in the northern temperate regions, namely in the south of Sweden and Norway, Denmark, and in all the lands bordering on the Baltic, the north of Germany, and part of Siberia. In the latter another very prevalent grain, buckwheat, is also much employed. In the zone where the prevalent wheat is generally to be found, barley being here chiefly cultivated for the manufacture of beer, and oats supplying food for the horses. To these there follows a zone in Europe and Western Asia where one finds barley freely furnished bread. The middle and the south of France, England, part of Scotland, a part of Germany, Hungary, the Crimea, and Greece, as also the lands of middle Asia, where agriculture is followed, belong to this zone. Here the vine is also found; wine supplies the use of beer, and barley is commonly less raised. Next comes a district where wheat still abounds, but no longer exclusively furnishes bread, rice, millet, and maize being also grown.

To this zone belong Portugal, Spain, part of France on the Mediterranean, Tunisia, the provinces of Asia Minor, further, the countries of the East, Persia, Northern India, Arabia, Egypt, Nubia, Barbary, and the Canaries; in these latter countries however the culture of maize or rice becomes more common. Here, and in some of them several kinds of **Sorghum** (Donra) and **Poa Alpina** come to be added. In both these regions of wheat, rye only occurs at a considerable elevation, oats however more seldom, and at last entirely disappear, barley affording food for horses and cattle. In the north the cultivation extends to the vegetable zone of the old continent, in China and Japan, our northern kinds of grain are very unfrequent, and rice is found to preponderate. The cause of this difference between the east and west, and between races and climates appears to be neither the manners and peculiarities of the inhabitants. In North America, wheat and rye grow as in Europe, but more sparingly. Maize is more reared in the western than in the old continent, and rice predominates in the southern provinces of the United States. In the torrid zone, maize predominates in America, rice in Asia; and both these grains in nearly equal quantity in Africa.

The cause of this distribution, without doubt, historical, for Asia is the native country of rice, and America of maize. In some situations rice is cultivated with equal facility in the tropics, wheat is also met with, but always subordinate to these other kinds of grain. Besides rice and maize there are in the torrid zone several kinds of grain as well as other plants which the inhabitants with food, either used along with them or entirely occupying their place. Such are: in the new continent, **Yams** (Dioscorea alata), the Manihot (Jatropha Manihot), and the Batatas (Convolvulaceae), the root of which and the fruit of the **Pisang** (Dioscorea Musa) furnish universal stores of food, and of some kind in Africa, **Doura** (Sorghum), **Pisang**, Manihot, **Yams**, and **Arthus hypogaea**; in the East Indies and on the Indian Islands, **Elaeis coromana**, E. striata, **Panicum miliaceum**, **Poa graminifolia**, and **Psathyrostachys**, the Sago, **Pisang**, **Yam** Beets, and the Bread-Fruit (Avicennia iacca). In the islands of the South Sea, grain of every kind disappears, its place being supplied by the bread-fruit tree, the pisang, and **Tacca pinnaflata**. In the tropical parts of Australia there is no agriculture, the inhabitants living on the produce of the sago, of various palms, and some species of **Arun**.

In the high lands of South America, there is a distribution similar to that of the degrees of latitude. Maize is cultivated in the southern parts of those countries, and in Van Diemen's Land. In New Zealand the culture of wheat is said to have been tried with success, but the inhabitants avail themselves of the **Acraciunum furnetum** as the main article of sustenance. Here also appears the contrast in the distribution of the growing kinds of grain, the earth may be divided into five great divisions, or kingdoms—the kingdom of rice, of maize, of wheat, of rye, and lastly of barley and oats. The first three are the most extensive; the maize has the greatest range of territory, the wheat the next greatest, and the greatest number of the human race,” Schomow, in Jameson’s ‘Philosophical Journal.’

The uses of this important tribe of plants for fodder, food, and clothing, require little illustration. The abundance of the productive parts of the different species, and their peculiarly well adapted for the sustenance of man; and if the Cereal Grasses only, such as Wheat, Barley, Rye, Oats, Maize, Rice, and Guineas corn, are the kinds commonly supplied, it is because of the large size of their grain compared with that of other grasses; for none are unwholesome.
in their natural state, with the exception of Lactium temu-
lentum, a common weed in many parts of England, the
effects of which are undoubtedly injurious, Bromus purus-
genes and catherines are said to be emetic and purgative; Bromus
mollis is also unhealthy, and Festuca quadrundens is
said to be poisonous; Molinia coerulea is injurious to cattle;
and some other species are supposed to affect the milk of
cows which graze upon them.
Among corn-plants not generally known may be mentioned
Eligia siliqua, called Natchez by the Coromandel coast,
and Nagla Rages, or Mand, evangelists in India; Sedum
Germanicum, yielding German millet; and Panicum frumen-
tacenum. There are many other species.

The value of grasses as fodder for cattle is hardly less than
that of other plants. The common fodder-grasses of Europe are
usually dwarf species, or at least such as do not rise
above four or five feet from the ground. The most
esteemed are Lactium perenne, Phleum, and Festuca pra-
tenis; Cynosurus cristatus, and various species of Poa
and dwarf Festuca. The fodder-grasses of Brazil are of far more
gigantic stature, and perfectly tender and delicate. In
Australia the favourite is Anthisuria australis, or Kangaroo
Grass; in India A. culta is also in request; but the most
common Indian fodder-grass is Durra, Doorna, or Hurry-
alee (Cynodon dactylon). Gama grass (Tripogon dactylon)
has a great reputation as fodder in Mexico; and attention
has lately been directed to the Tussac Grass of the Falk-
lands (Festuca fertilissima), a species forming tufts five or six
feet high, and said to be unrivalled for its excellence as food
for cattle and horses.

The fragrance of our sweet Vernal Grass is by no means
confined to it; other species possess the same quality, which
is connected with the presence of aromatic secretions, which
has led to its being recommended to the nostrils of medical
practitioners. Sugar is a general product of grasses. It
exists in great quantities in the Sugar-Canes (Saccharum
officinarum). Maize so abounds in it, that its cultivation has
been prosed in lieu of the sugar-cane.

For economical purposes Grasses are of much importance.
The strong stems of the bamboo are employed instead of timber and cordage. The citull of some species
contains silica, which occurs in large masses after the burning
of a hard rock, or a slice of hay; in the shape of a colour-
less glass mass.

(Lindley, Vegetable Kingdom; Babington, Manual of
British Botany.)

GREEN IRON-EARTH. [Minerology, S. 1.]

GREENOUGH, HORATIO, American sculptor, was born in
Boston, United States, September 6, 1805. From his
earliest childhood he showed a great facility in drawing and
modelling, and his tastes were carefully cultivated; but it was
not until after he had been placed in academical training
that he began seriously to contemplate the adoption of
sculpture as a profession. Sculpture had then few prac-
titioners in America, and none of any mark; Greenough
that he proceeded to Rome in order to study the art.
Rome consequently furnished a residence for some years, and he
derived much professional advantage from the friendly serv-
ices of Thorvalden. His health however gave way, but it
was speedily restored by a visit to his native land. There
however he did not stay long. On his return to Europe he
remained long enough in Paris to execute a clever bust of
Lafayette, and then proceeded to Florence, where he fitted
up a studio, and where during a residence of several years,
his principal works were executed. Of these the most
important perhaps is the work which he superintended at
Washington, which now stands in the grounds of the Capitol at Wash-
ington, and the 'Rescue,' or, as it is sometimes termed, the
'Pioneer's Struggle,' now in the Capitol itself: both of these
works, so far as can be judged, are a harmonious union of the
timework of considerable originality and power, is intended to
ty the struggle between the native and European races,
and consists of a group of a pioneer rescuing his wife
and child from an Indian. Besides these he executed several
other works, and his intentions, whether poetical or
theorific, are always equalled by his workmanship. His
some very pleasing and graceful poetical figures and busts

He returned to America in 1851 to superintend the erection
of his group of the 'Rescue,' and eventually determined not
to again to return to Europe. But he had become imbued in
an Italian climate, and his constitution proved unable to with
stand the variations of an American one. After a severe
illness he died December 16, 1852.

Greenough will probably not ultimately rank among the
foremost of modern sculptors, but he is the one perhaps to
do doubt continue to occupy, a very respectable position;
while he will always retain a prominent place in the history of
American art as the first of his countrymen who obtained
an European reputation as a sculptor. Greenough's attainments
are generally attributed to the fact that he wrote both in verse and prose.
In private life, while
thoroughly unassuming, few men have been more esteemed.

GREENECKITE. [Minerology, S. 1.]

GREGAN, JOHN EDGER, claims notice as one of those who have contributed by their works to the
architectural improvement of the city of Manchester, where
great progress in art has been manifested during the last
twenty years. Gregan was born in Ireland; it is believed
at Dunmurry. He received an excellent general
education at Edinburgh, and acquired his first professional
knowledge from Mr. Walter Newall, architect, at Dunmurry.
About the year 1856 or 1857 he went to Manchester, where
he was for some time an assistant to Mr. T. Atkinson.
He then became an architect, who may be said to have commenced the
improvement which has been referred to. Mr. Atkinson left
Manchester in the year 1840, when Gregan commenced prac-
tice on his own account, and wholly by merit and experience.
His prominent position include several churches and schools in the neighbourhoods of Man-
chester, Bolton, and Preston, and the chapel of the Diocesan
Training School at Chester—these being in the medieval
style. He was the architect of St. John's Presbyterian
Churches at Green-Heys and Ancoats, school to the latter, and the Jews' school at Cheetham Hill—all of
the style of Northern Italy; several private houses at Man-
chester and neighbouring towns; warehouses (the class of building
which the character of Manchester is expressed) the lodges to the public parts of
the same city, and other buildings. His best work however, and it is of great merit, is the bank of Sir Benjamin Heywood,
Bart, and Co., of which an illustrated account may be found in the 'Builder' (vol. vi.), where also is a few, or an elev-
ton, of one of his warehouses (vol. viii.). The bank is de-
signed in an adaptation of the Venetian Italian style—
with careful attention to beauty of detail. The new 'Mechanical
Institute,' which Gregan, from his being a Fellow of
the Manchester Royal Institution, and took great interest in the local School
of Design, the establishment of the Free Library, and other
institutions. He possessed a cultivated taste in general art,
was an accomplished amateur chemist, and was a skilful performer
on one or two musical instruments.

GREGORY XII., Mauro Capellari, was born September 18,
1785, at Belluno, in the Lombardo-Venetian kingdom.
He entered at an early age into the Camaldolese order
and was elected their vicar-general. On the 21st of March 1823, Leo
XII. created him a cardinal, and soon afterwards appointed him prefect of the college De Propaganda Fide. Under Pius
VIII. He conducted the negotiation on mixed oaths with the kingdom of Prussia, and was the author of the celebrated pamphlet opposing the Emperors. He was elected pope, and crowned on the 6th of February. In honor of the founder of the college de Propaganda Fide, Gregory XV., he assumed the name of Gregory XVI. He was a man of respectable character in private life, but his criticism of the great theological questions of his time led to his exclusion from his temporal government harsh and despotic. In the early part of his reign he called the Austrians to suppress the disturbances which had broken out in the Legations, and his pontificate was considerable for the suppression of these disturbances in his subjects. He died June 1, 1846, and was succeeded by the present pope, Pius IX.

GROTEFEND, GEORG FRIEDRICH, a distinguished philologist and antiquarian, was born at Münden in Hanover on June 9, 1770. He was educated in his native town and at Hildesheim till 1796, when he proceeded to Göttingen, where he became intimate with Heyne, Tychsen, and Heeren. On the recommendation of Heyne he was appointed in 1797 assistant teacher in the Göttingen town school; and after he had made himself known by his work "De Paigraphia sive Scriptura Ebraica," which was done under the direction of Dr. Siemens, he became director of the Gymnasium of Frankfurt-on-the-Main in 1803, and shortly afterwards con-rector. Besides many learned contributions to the Allgemeinen Cyclopedia of Ersc and Grüber, and to other periodical works, he published in 1817 his celebrated "Handbuch des vergleichenden Lateinischen," and founded in 1817 a society for the investigation of the German language. In 1821 he was called to be director of the Lyceum at Hanover, which thenceforth became his residence. In 1822, he published an enlarged and reprinted edition of his "Lateinische Grammatur" in 2 vol. 4to, and a smaller one for the use of schools in 1822. His most noticeable works however are those relating to the deciphering of the eastern cuneiform inscriptions, on which he expended much and apparently directed labour; and those devoted to an investigation of the old Italian languages and geography. Among these works are his 'Nemén Beträge zur Erläuterung der Persepolitanische Keilschrift.' (New Contributions towards the Explanations of the Persepolitan Cuneiform Inscriptions), 1827; and 'Neme Beiträge zur Erläuterung der Babylonische Keilschrift,' 1840. For early attempts these works possessed considerable merit, but their value has been lowered by the indefatigable labours of more recent investigators. The first public notice of these productions was given between 1835 and 1838, "Rudimentos Lingae Umbriæ ex inscriptionibus antiquis edita," in 1839 "Rudimentos Lingae Oscae," 'Die Münzen der griechischen, persischen und indoscythischen Königre von Bactrien und Gandhara,' and 'Eroten, Nomada, and Indo-Sythian kings of Bactria and of the Countries on the Indus; and in 1840-42, in five parts, his investigation 'Zur Geographie und Geschichte von Altitalien,' a work remarkable for the copiousness of its materials and the bold felicity of many of its theories. The part he took in the controversy respecting the genuineness of Sanchunianthos' 'History of the Phœnicians,' has been already mentioned. [Sanchuniathon.] Grotefend has also published a history of the Lyceum at Hanover. He died December 16, 1849.

GROUCHY, EMMANUEL, COMTE DE, Marshal and Peer of France, was born in Paris, October 23rd 1786. He entered the artillery branch of the army in 1780. He was attached to the corps of horse, 1794, and in the course of the ensuing year, became one of the gardes-du-corps of Louis XVI. However, no sooner did the first dawn of the revolution appear than he quit the gardes-du-corps and ardently embraced revolutionary principles. In 1796, he was made colonel of the 2nd regiment of dragoons and next year he became major-general, and was appointed to head the cavalry attached to the army of the Alps. In that campaign Savoy was conquered by Montenquieu and annexed to France, General Grouchy having mainly contributed to the rapidity of this conquest. In 1797, a year already to be esteemed the first cavalry officer in the French armies. In 1793 he was ordered to join the army of the Côtes de Brest in La Vendée, relieved Nantes, besieged Chazotte, and by his skilful maneuvres at the head of the vanguard in the last wing he arrested the progress of the insurrection, pre-
26, 1814, at Le Rothière, February 1, and at Vauxolph, February 14. His bravery and skill, at this last battle, rang throughout all France; the auger of Napoleon, which had lasted ten years, gave way before it, and Grouchy was carried away.

After the battle of Ligny, June 16, 1815, Marshal Grouchy was commissioned to pursue the retreating army of Blucher with a force of 34,000 cavalry, and 100 pieces of cannon. In consequence of these orders, he found himself posted at Wavre, opposite to the position of the Prussians, and the French general Thielmann, whilst Napoleon was fighting at Waterloo, on the 18th. The marshal heard the report of artillery, and was strongly urged by his lieutenant-generals to make a personal sortie to the point, where he declared himself bound to obey the orders he had received from the emperor on the 17th. Fatal as the battle of Waterloo proved to the French arms, nothing was publicly said at that period against Grouchy's conduct, nor for three years after. After the second abdication of Napoleon, the provisional government appointed the marshal to the uniformed command of all the corps of the grand army; but the entire muster only amounted to 45,000 men.

Bunzfist from France, after the return of Louis XVIII, he withdrew to the United States, where he was living in 1816, when the narrative of the battle of Waterloo, dictated to General Gourgaud, at St. Helena, was published. In this account a charge of treachery was made for the first time against the marshal, who declared he had returned to France to assist in the revolutionary uprising. He was reinstated in all his titles and honours in 1821, by Louis Philippe, and died at Saint-Etienne, May 29, 1847, having been sixty-seven years in the French armies.

GROUND IVY. [Nawara, S. 1.]
GUACALATE. [Nawara, S. 2.]
GUANINE. [Nawara, S. 2.]

GUATEMALA, Republic of Central America, occupies the table-land of Guatemala, with the hilly country between it and the Gulf of Honduras, and a portion of the table-land of Yucatan. It lies between 24° 40' and 19° 10' N. lat., 81° 15' and 93° 30' W. long. On the S.E. it is bounded by the Republic of Salvador; E. by Honduras; N.E. by the Gulf of Honduras and the British settlement of Roatan; W. by the Atlantic; W.S.W. by the Gulf of Yucatan; W. by Chiapa; and S. by the Pacific Ocean. The area is about 50,000 square miles; the population about 600,000.

Coast-line Service, A.—The general bearing of the Pacific coast from the Salvador boundary of the State to the Barra de Guacalate in W. by N., and thence to the Rio Sintalapa, the boundary between Guatemala and Chiapa, it is N.W. The shore is for the most part low, the descent from the land to the sea being abrupt, and a strip of lowland, from 50 to 30 miles across, being left in place of the sea; but in many places the shore is high and rocky, and several rocky barriers lie off it. The only port at present frequented on the coast is that of Yalapa, at the mouth of the Rio Miche- tuco. There are a few small harbours on the coast of eastern Guatemala, but the harbour is little better than a roadstead, affording no protection for shipping. Ocos, further north, formed by the Barra de Orocos, is also an available port, but, owing to the absence of inhabitants, is not resorted to. The low tracts along the coast are very thinly peopled. On the northern coast Saino Tomas, in Honduras Bay, is a good and well-sheltered port; and somewhat inland, in the lake known as Golfo Dulce, is the port of Yabal, in some respects the principal port of Central America. Port of Ocos was designed for that market being brought to it by vessels, and thence transported to the interior by mules: owing to a bar at the mouth of the Rio Dulce, Yabal is inaccessible to vessels drawing over 7 feet of water.

The table-land of Guatemala occupies all the countries between the isthmus of Chiapasimn and that of Tehuantepec in Mexico; the island in the interior of the peninsula of Yucatan, usually called the table-land of Yucatan, forms its most elevated projection. Near its southern borders, about the town of Guatemala, its highest point is 2200 feet above the sea, and this may be considered as the mean height of that portion which is south of the Rio Motagua. But north of this river the country rises higher. The most elevated part of it appears to be that between 15° and 16° 30' N. lat. From this point it begins to lower gradually, and its north-western edges, which belong to the Mexican state of Chiapa, are incised by deep and sometimes wide valleys. No continuous range of any considerable elevation traverses this plain, the surface of which is slightly undulating, like the central parts of England; but here and there it is traversed by a range of hills, rising a few hundred feet above the plain. The descent from this plain to the low shores of the Pacific is extremely steep, and consists when seen from that side, it has the appearance of a mountain range, an illusion which is confounded by a few lofty volcanoes standing near the edge of this descent. The most remarkable are the active volcanoes of Atitlan, Coatepeque, and San Juan, situated S. and N.W. of the town of New Guatemala, of which the Volcano de Agua (or Water Volcano), according to Colonel Galindo, is 12,620 feet, but according to other authorities 13,076 feet high; and the Volcano de Fuego (or Fire Volcano) is 12,500 feet high, but which has not been ascended. All the volcanoes, whether active or extinct, are situated near the Pacific, and are in line with those of Salvador and Nicaragua. The eastern border of the table-land, by which it descends to the Gulf of Honduras, is cut by deep valleys, between which the high land takes the shape of ridges, which extend to a great distance, and in some places, as between the Rio Motagua and the Golfo Dulce, advances to the very shores of the sea. The country between the table-land and the Gulf of Honduras, may therefore be considered as a succession of valleys and ridges, except the part to the west and north-west of the Golfo Dulce, which is a low plain.

The state is well watered by a large number of rivers, but none of them are navigable. The Golfo Dulce, Polochic, and Motagua. The Rio Dulce, though short, is the most important river of Central America, being the channel by which the Golfo Dulce discharges its waters into the Gulf of Honduras, 15° 30' N. lat. The Golfo Dulce is about 20 miles long, and of considerable depth, except on its bar, where there are only 6 or 7 feet water.

The Rio Polochic rises near the village of Tactic, on the table-land of Guatemala, but soon descending into a wide and deep valley, the river turns to the south-west, and empties itself into the Gulf of Mexico. It is about 60 miles long, and narrow, with a few shoals, some 3 miles wide, and with a few shoals, some 5 miles wide. At its mouth the river turns to the north-east, and falls into the Gulf of Honduras about 15 miles west of Omoa. By means of this river a considerable quantity of the produce of the interior, in small canoes, is sent into the interior of Guatemala; they are transported from Guatla to the places of consumption by mules.

The Lacanata, which rises in this state and separates it for a considerable distance from Yucatan, becomes an important river after its entry into the state of Yucatan. The rivers which enter the Pacific are numerous, but have all a short course. One of the most important is the Motagua, which at its mouth forms the harbour of Yalapa, the port of the city of Guatemala.

There are four rather considerable lakes in the state. Of these, that called Golfo Dulce, noticed above, is the most important, as by means of it most of the foreign trade of the republic is carried on. The lake of Patz, situated in the most northern district of Vera Paz, on the table-land of Yucatan, is of an oval form and about 70 miles in circuit. It contains several islands, on the largest of which is a small fortress and a collection of houses forming the village of Puerto de Dote, and one of the minor islands has been the seat of the city of Guatemala, and near the western edge of the table-land. It is about 18 miles long and 9 miles broad, surrounded by lofty heights, including the volcanos of Atitlan, Coatepeque, and San Juan, and an extensive forest, and a magnificent outlet, though several small rivers fall into it. The lake of Amatitlan, 18 miles south-east from the city of Guatemala, is 9 miles long and 3 miles wide, and of great depth. It is much resorted to as a bathing-place by the inhabitants of
the city during the season from February to April; and near the lake are several hot and mineral springs. The Rio Michat is the chief supply.

Climate, Soil, Productions.—The climate of the table-land is that of a perpetual spring; the thermometer scarcely varies throughout the year. The average heat in the month of July is from 65 to 70 Fahr.; but during the north wind it sometimes descends to 50. From May to May, it sometimes though rarely descends 30 degrees within a few hours. The rainy season usually sets in in May and lasts till October; but rain seldom falls except between the hours of day and darkness. The wind is not very constant, and changes them continues for about a month. The other productions of this district are maize and wheat, sugar and coffee, most of which however is required for home consumption. The principal towns are Guatemala, the capital of the state, Amatitlan, Escuintla, and Suchitoto. The table-land of the lake of the same name, which formerly depended on the persons who annually resorted to it for bathing, is now, in consequence of the great increase in the rearing of cochinal, a rich and flourishing place, having a population including the suburbs of upwards of 5000. The greater of the former corregimientos, and contains about 4000 square miles. The surface is very much broken, and the soil, especially in the valleys, very fertile. The climate is colder than in some other parts of the state. Wheat, maize, and fruits are the chief products. Sheep are bred in large numbers. Jerga and other coarse woollens are manufactured. At least three-fourths of the inhabitants are Indians, who are mostly engaged in agriculture or weaving: twelve or fourteen of their villages are placed around the lake of Atitlán, the beauty of the centre of Sololá. From the midst of this lake, and the volcano of San Pedro. The chief towns of this department are Sololá, population 8000, Atitlan, and Masateunga, but neither of them is of any importance. The exports are confined to few articles. Of these the most important is that of cochineal, which was introduced into Guatemala as late as 1811, and did not for several years produce more than sufficient for home consumption. In 1811 about 12,000, which were imported 60,000, and in 1851 had increased to 1,489,100 lbs. The other articles of export are chiefly mahogany and other woods employed in cabinet work: vanilla, saharsapalli, and other medicinal roots and barks: spices, rice, tea, and cotton are also exported in small quantities. The principal article of domestic consumption is maize. British cotton and dry gossips, linen and silk fabrics; porcelain and fine earthenware; fancy goods, wines, &c. In 1851 the exports amounted to 984,488 dollars; the imports to 1,264,420 dollars.

Departments, towns, &c.—Guatemala is divided into seven departments (corregimientos), which, with their chief towns, are as follows:

1. Guatemala occupies the south-eastern portion of the territory, has an area of nearly 6000 square miles, and a population of about 90,000. The surface of the country is considerably diversified, the climate equable and genial, and the soil remarkably fertile. This and the following department form an immediate part of the valley of Guatemala, and extend from the lake of the same name, which formerly depended on the persons who annually resorted to it for bathing, is now, in consequence of the great increase in the rearing of cochinal, a rich and flourishing place, having a population including the suburbs of upwards of 5000. The greater of the former corregimientos, and contains about 4000 square miles. The surface is very much broken, and the soil, especially in the valleys, very fertile. The climate is colder than in some other parts of the state. Wheat, maize, and fruits are the chief products. Sheep are bred in large numbers. Jerga and other coarse woollens are manufactured. At least three-fourths of the inhabitants are Indians, who are mostly engaged in agriculture or weaving: twelve or fourteen of their villages are placed around the lake of Atitlán, the beauty of the centre of Sololá. From the midst of this lake, and the volcano of San Pedro. The chief towns of this department are Sololá, population 8000, Atitlan, and Masateunga, but neither of them is of any importance. The exports are confined to few articles. Of these the most important is that of cochineal, which was introduced into Guatemala as late as 1811, and did not for several years produce more than sufficient for home consumption. In 1811 about 12,000, which were imported 60,000, and in 1851 had increased to 1,489,100 lbs. The other articles of export are chiefly mahogany and other woods employed in cabinet work: vanilla, saharsapalli, and other medicinal roots and barks: spices, rice, tea, and cotton are also exported in small quantities. The principal article of domestic consumption is maize. British cotton and dry gossips, linen and silk fabrics; porcelain and fine earthenware; fancy goods, wines, &c. In 1851 the exports amounted to 984,488 dollars; the imports to 1,264,420 dollars.

Divisions, towns, &c.—Guatemala is divided into seven departments (corregimientos), which, with their chief towns, are as follows:

1. Guatemala occupies the south-eastern portion of the territory, has an area of nearly 6000 square miles, and a population of about 90,000. The surface of the country is considerably diversified, the climate equable and genial, and the soil remarkably fertile. This and the following department form an immediate part of the valley of Guatemala, and extend from the lake of the same name, which formerly depended on the persons who annually resorted to it for bathing, is now, in consequence of the great increase in the rearing of cochinal, a rich and flourishing place, having a population including the suburbs of upwards of 5000. The greater of the former corregimientos, and contains about 4000 square miles. The surface is very much broken, and the soil, especially in the valleys, very fertile. The climate is colder than in some other parts of the state. Wheat, maize, and fruits are the chief products. Sheep are bred in large numbers. Jerga and other coarse woollens are manufactured. At least three-fourths of the inhabitants are Indians, who are mostly engaged in agriculture or weaving: twelve or fourteen of their villages are placed around the lake of Atitlán, the beauty of the centre of Sololá. From the midst of this lake, and the volcano of San Pedro. The chief towns of this department are Sololá, population 8000, Atitlan, and Masateunga, but neither of them is of any importance. The exports are confined to few articles. Of these the most important is that of cochineal, which was introduced into Guatemala as late as 1811, and did not for several years produce more than sufficient for home consumption. In 1811 about 12,000, which were imported 60,000, and in 1851 had increased to 1,489,100 lbs. The other articles of export are chiefly mahogany and other woods employed in cabinet work: vanilla, saharsapalli, and other medicinal roots and barks: spices, rice, tea, and cotton are also exported in small quantities. The principal article of domestic consumption is maize. British cotton and dry gossips, linen and silk fabrics; porcelain and fine earthenware; fancy goods, wines, &c. In 1851 the exports amounted to 984,488 dollars; the imports to 1,264,420 dollars.
wooden cloth, earthenware, and wooden utensils. The other towns are Momostenango, Guateguetango, and Jacaltenango.

6. Chiquimula, occupies the north-eastern extremity of the state, bordering on the republic of Honduras; its area is nearly 6,000 square miles; its population about 80,000. The surface is considerably diversified, and in parts very fertile; their waters are stored up by the Guatemala and the Bay of Honduras are hot, moist, and unhealthy. Tobacco, cotton, rice, and sugar are raised largely, with maize, frigoles, &c. The sugar is grown chiefly for distillation or for making cane-vinegars and spirits of the drink of the Indians. Horses, mules, and cattle are reared in large numbers. The chief towns are Chiquimula, population 4,500; Aguaaguanil, 3,600; Jalapa, 3,500; Ixilpeque, 3,200; Mitl, 3,300; Quezaltepeque, 4,600; Zacapa, 3,000; and the little port town of Yoro, 2,000.

7. Vera Paz, the largest of the seven corregimientos, comprehends the projecting tract of country which forms the most northern part of the republic; the area is about 11,000 square miles; the population is estimated at 65,000, of whom nine-tenths are Indians. The country is very varied in surface and character of soil: but comparatively very little of it is subject to crops of rice, potatoes, and maize, and other precious timber-trees abound; the coffee, cacao, indigo, and poppy plants are said to be indigenous in the forests. In the northern part of Vera Paz is the lake of Peten. The most populous town is Coban, situated in a remarkably fertile valley; it is, with a population of 1,000, nearly all Indians, who are industrious and wealthy, possessing fine plantations of sugar-cane, bananas, pimentos and various kinds of fruit; the other towns are Salama, population, 4,500; Cajabon, 4,000; and Rabanal, 6,000, but none of them can be said to be very important.

Government, &c.—According to the constitution of the 19th of October, 1851, the executive is confided to a president elected by a general assembly, composed of the legislative council of the archbishop of Guatemala and the members of the supreme court of justice, and the members of the council of state having a deliberative voice. The president is elected for four years, but is eligible to be re-elected. The legislative assembly consists of 59 members. The council of state is composed of the ministers, eight councillors chosen by the legislative assembly, and of others appointed by the president. The revenue and expenditure average somewhat over 400,000 dollars. The debt amounts to 1,265,000 dollars; the army consists of 1,000 men, with a patriotic corps and a militia of 5,000 men.

The population consists of aboriginal tribes, some of whom live in a state of almost perfect independence, but the main body have obtained all the rights of free citizens of the republic, and have become a part of the population of the descendants of Europeans, and of the mixed offspring of Europeans and Indians, who are known as "ladinos." The Roman Catholic is the established religion, and there are few open dissenters. The church is presided over by the Archbishop of Guatemala.

During the Spanish occupation Central America was termed the kingdom of Guatemala, the city of Guatemala being the capital and seat of Government. During the struggle for independence it remained quiet and subject to Spain; but on the declaration of independence in 1821 it was for awhile united to the Mexican empire of Iturb. On the publication of the new constitution, July 2nd, 1828, by which the federal state of Central America was formed, Guatamala became one of the united states. This union was however after a short time dissolved, and Guatemala then became an independent republic, and has so continued to the present time.
and he saved the Frenchman by knocking down the Irishman. His prisoner guided him to a tower, where he found the prisoner and governor of the place, and some other officers, who had shot themselves up from the now victorious English soldier. He summoned them to surrender, and the door was unbarred; but Pat Lowe, who had rejoined him, called out, 'Dear Mr. Gurwood, they will murder you!' and as he stepped forward with the sword when he was about to take him, Pat Lowe seized the sword in his body; but his alarm ceased on finding himself kissed by the person who had seized him, who added that he was the governor, General Barrie, and that he yielded himself his prisoner. Gurwood conducted him to Lord Wellington, whom he found to be a most reasonable man, and who said, 'Tell them you will take him!' and, on his replying in the affirmative, handed him the governor's sword, which had just been surrendered, with the observation, 'Take it, you are the proper person to handle it.' Gurwood was thus enabled to reassert the privilege when every other officer in the English army wore a regulation sword. From this time he became a noted officer; but though he served with distinction during the rest of the Peninsular war, and at Waterloo, where he received a severe wound, the rank of colonel was the highest that he attained, and he did not become full colonel till 1841.

In 1830 he was placed on the unattached list, and shortly afterwards became private secretary to the Duke of Wellington. This appointment led to a very successful publication. In 1834 he was appointed editor of The Despatches of Field-Marshal the Duke of Wellington. K.G., during his various campaigns in India, Denmark, Portugal, Spain, the Low Countries, and France, from 1799 to 1815, compiled from official despatches in the possession of the Earl of Ellesmere and the Duke of Gurwood. The work extended, with a volume of index, to thirteen volumes; the publication of it occupied the colonel for a series of years, and its popularity was unexpected and unexampled. No collection of official documents of any length has ever found its way into so many libraries and so many hands. A second edition was called for, and an abridgement into one volume was issued to satisfy the curiosity of those who could not purchase the complete edition. This abridgement, the Duke of Wellington's private papers to have been materially raised by the publication, and most of his popularity in later life was based on the Despatches."

Colonel Gurwood urged him to give his consent to other publications bearing on his military career, but he did not always succeed. The colonel was in the habit of showing his friends a paper by the Duke on the battle of Waterloo, in answer to the observations on the subject by the Prussian general Clausewitz, and was much surprised at finding that one passage in it was incorrect. He did not dare to say so, and was about to leave the room, when he discovered that he had found in the book the word in that magazine for July 1844, without the slightest intimation from whose pen it proceeds—a fact which would indeed never be conjectured by any one perusing the article without previous information as to its authorship. The Duke had supplied the late Earl of Ellesmere some observations on the battle which are interwoven with his article on Alison's History of the War in the Quarterly Review. In return for the colonel's services the Duke appointed him Deputy-Governor of the Tower of London. He again visited Spain in company with Lord Eliot, the present Earl of St. Germans, to endeavour to mitigate the cruelties of the civil war between the Carlists and Christinos, in which neither party gave quarter; and through his influence to prevent the French from using the loyalists as spies. From the time of the publication of some portions of Napier's History of the Peninsular War in 1840, Colonel Gurwood was involved in a disagreeable controversy respecting the circumstances of the capture of the governor of Ciudad Rodrigo. An offshoot of the rank of fully, who had commanded one of the storming parties, made a statement in October 1838 to the effect that (be the major) had accepted the surrender of the governor; that a sword, afterwards found to be that of an aide-de-camp, had been presented to him, and that Gurwood was engaged with two officers who held bold of him for protection, one on each arm. Lieutenant Gurwood came up and obtained the sword of the governor; on seeing him present which on the ramparts, the major, according to his own account, "turned on his heel and left the spot." The major died in 1839, and this statement was made public in the following year in a second edition of that portion of Napier's History of Ciudad Rodrigo, the first having stated that "Mr. Gurwood was in the fight, but never engaged amongst the foremost at the lesser breach, received the governor's sword." Colonel Gurwood had been in garrison with the major in 1834 at Portsmouth, and always wore the sword; but the major had never produced any remark from that officer. A long and vociferous discussion ensued on the point, which was brought to a close by a very singular incident. Gurwood did not know the name of the French officer whom he had rescued from Pat Lowe; and when the latter was reassigned to the post, it was important to show the justice of his claims, as the Frenchman had guided the Englishman to the tower where the governor was found, and witnessed what then took place. Gurwood was turning over the publication when the colonel found a letter addressed to Lord Wellington in 1818 by a captive French officer named Bonfilh, who might, he inferred, be the person he was in search of. He made inquiries in Paris to ascertain if M. Bonfilh was still alive, found that he was, wrote to him, and received a letter dated the 1st of May 1844, in which M. Bonfilh informed him that he was indeed the officer whose life he had saved, and gave a statement of all that he remembered of the night of the storm, which he had related in some few unessential particulars from the recollections of the day. He had in all but a few words heard the colonel's statement, and was irreconcilable with that of the major. The colonel read it with feelings which he declared it impossible to describe. He visited M. Bonfilh at his residence in Paris, and introduced him in a pamphlet, of which he printed only fifty copies for private circulation, from one of which these particulars are taken. The preface is dated on the 14th June 1845, and it was his last literary effort. On the 30th of December in the same year, he died, and the army lost an officer who had contributed at the inquest to the effects of the wound he had received so many years before at Ciudad Rodrigo, he terminated his life by his own hand at Brighton, leaving a widow, a French lady, and three daughters."

GUTTA PERCH — [Leonard's 7.] GUYON, general Richard deBauaure, was born March 31, 1813, at Walcott, near Bath, Somersetshire, in which city he received his early education. His grandfather was a captain in the Dragon Guards; his father, John Guyon, of Richmond, Surrey, was a commander in the royal navy, and died in 1844. Richard Guyon was intended for the army, and at an early age held a commission in the Surrey militia. At the age of eighteen he obtained a commission in the 80th regiment, and was appointed aide-de-camp to Field-Marshal Lord Castlereagh, and after some years' service attained the rank of lieutenant, and was appointed aide-de-camp to Field-Marshal Baron Sperny, commander of the Hungarian life-guarda. In 1833 he married the daughter of the Bishop of Wells, and soon afterwards retired to the neighbourhood of Pelsa, where his wife's relations resided, and where he spent his time in country occupations and field-sports.

In September, 1845, when Jellachich, the Ban of Croatia, invaded Hungary, Guyon offered his services to the Hungarian diet, and received the appointment of Major of the Honveds, or national guards. On the 29th of September he contributed materially to the defeat of Jellachich at Bakoro. In the battle of Schwedew, near Vienna, on October 30th, Major Guyon with his raw troops achieved at Mannwörth the only successes of that disastrous day, when, his horse having been shot under him, he led his men to the charge on foot, and armed them with the muskets of the slain Austrians, in place of the swords with which many of them had fought. He was rewarded by being raised to the rank of Colonel on the field of battle. He was afterwards raised to the rank of General at Debrecin. He commanded the rear of Gergéi's army on the march from Pesht to Upper Hungary; and at Lipiazi, on this 10th of February, by a daring and skillful effort saved the baggage from the pursuing Austrians. On the 5th of February, with 10,000 Hungarians, he stormed the defiles and heights of Branyansko, defended by 25,000 Austrians; and bringing to a close the campaign, returned to a large amount, and cleared the way for the van of the army to pass, Gergéi having vainly attempted to turn the defiles by a flank movement. At the battle of Kapolna (February 20) he commanded a division of Domhmany's army. On the 21st of April he entered the fortress of Komorn with a small body of troops, though it...
Gymnarchus, a genus of Malacocephycous Apodid Fishes. The body is long and oval; the gill opening before the pectoral fins; dorsal fin running the whole length of the back, pointed; anal fin of the same length—a smallish, much small, with a single row of cutting teeth. G. Niloticus is the only species; it inhabits the Nile.

Gymnemota, a genus of plants belonging to the natural order Astereidaceae. It has a sub-urecrose 6-leaflet corolla, the throat usually crowned by five scales or teeth inserted in the recesses between the segments of the corolla. The staminate corona is wanting. The authors terminate by a membra, the pollen masses are erect, fixed by the base. The follicles are usually shrub, natives of the East Indies, the tropical parts of Australia, and Equinoctial Africa. The leaves are opposite, membranous, and flat. The umbels imperfect and cymose. In the greater number of species the stamens are partly included in the ovaries; the seeds are globose, with a gland-like body or fleshy tuft at the base of each filament. G. lactiferum, Cow-Plant, or Milk-Bearing Gymnema, has an erect stem, or rather twining; the leaves are on short petioles, ovate, bluntly acuminate, usually unequal-sided; the vessels are many-seri, slender, running the throat of the corolla crowned by five fleshy tubercles; the tube furnished with double pilose lines running from the tubercles. It is a native of Ceylon, where the milk of the plant is used as a substitute for cow's milk, and the leaves are boiled with food.

G. tingens is a native of Pegu. It has a twining globular stem, cordate leaves, acuminate to oval; the umbels or corymbs often twin, at first shorter than the petioles, and later spiral elongated; the glands of the filaments more than half shorter than the stamens; follicles cylindrical, spool-shaped; stigmas simple, oval, mucin, crowning the tube of the corolla, and therefore exceeding the stamens. The flowers are large, numerous, and of a pale-yellow color. The stamens of this plant a green dye is prepared by the Burmese. Seventeen species of this genus are enumerated, none of them of any particular interest.

Lycystis, or Smellible Kingdom; Don, Dich tromyemata Plants.

Gymnetrus, a genus of Fishes belonging to the group of Riband-Shapeed Asaheilort. It has the following characters:—Body elongated, compressed; a single dorsal fin extending the whole length of the back; ventral cleft ending each of a single ray, only sometimes, the anus dilated at the end; no anal fin; teeth pointed, small. The species of this genus have very rarely been obtained entire. They have generally been taken dead, and consequently have been crushed and mutilated. Of the species of the genus, Mr. Yarrell says, "three of these belong to the Mediterranean, two to the seas of the North of Europe, and two to India. One northern species, besides one of those apparently belonging to India, has been taken on the shores of the Baltic, and is a native of the coast of Poland, once in Scotland; that of India, once on the coast of Cornwall." G. Haukentu (Bich), Hawken's Gymnetrus, the Oest Gymnetrus, the Cell Conin of Cornwall. This species has been taken in Cornwall. The following description has been drawn up by Mr. Conch from a drawing and notes of a specimen taken in a net at Mont's Bay in 1791—"The length without the extremity of the tail, which was w. 36 feet; the depth, 10.9 inches; thickness, .9 inches; width, 9 inches; width, 9 inches; with an enduring jaw, long and slender; eye large; pectoral fin round; no anal fin; the dorsal fin reaches from above the eye to the tail. The restrictions are formed of four long radial processes, proceeding from the thorax, and ending in a fan-shaped appendage, of the back and bellies dusky-green; the sides whitish; the whole varied with dark and spouts of a darker green; the fins crimson."
specimen of this fish caught off the coast of Northumberland, was exhibited in London at the time the discovery of the Great Sea-Serpent was announced, and was supposed to explain the nature of this discovery.

The Gymnura auricula of Cuvier, the Vasaen, or Deal-Fish, has been referred to the genus Trachypeters. [Trachy-

The Gyridinidae, a family of Coleoperae insects belonging to the section Pentamerae, and the sub-section Hydrophages or Water-Beetles, and distinguished by the minute size of the antennae, which are minute on the head, and shorter than the head, the second joint being dilated into a kind of ear externally; the two fore legs are long and advanced in front like arms, but the four posterior legs are very short and compressed, but broad, and is four in number, two being placed above and one below: the palpi are very small; the thorax short and transverse; and the elytra oval, depressed, and oblique at the extremity, leaving the tip of the abdomen exposed. This family corresponds with the genus Gymnura of Linnaeus, and unlike the Dytiscidae to which they are nearly allied, these insects are distinguished by the metallic brilliancy of their covering; living for the most part on the surface of the water, they receive the impressions of the light in a more direct manner than the Dytiscidae, and are accordingly ornamented with tints of a brassy or bronzed metallic hue, which glitters in the sun in the greatest degree. The velocity with which they execute their evolutions upon the surface of the water is really surprising, and has obtained for them the name of Torquietaux by the French, and Wirglises and Waterflies by the English. Sometimes indeed they remain stationary for a time, so that it seems easy to secure them, but on the least motion they are instantly alert, escaping with surprising agility and diving to the bottom of the water. The situation of their eyes adds greatly to their defence, enabling them to see objects both above and below them. In the 'Journal of a Naturalist' we find the following account of their proceedings. "When water quiet, still water affords a place of action to a very amusing little fellow (Gymnura natator), which about the month of April, if the weather be tolerably mild, we see gambling upon the surface of the sheltered pool; and every school-boy who has angling for minnows in the brook is well acquainted with this merry little swimmer in his shinning black jacket. Retiring in the autumn, and resuming all the winter in the mud at the bottom of the pond, it awakens in the spring, rises to the surface, and commences its summer sports. They associate in small parties of ten or a dozen near the bank, where some little projection forms a bay or renders the water perfectly tranquil; and here they will circle round each other without contention, each in his sphere, and with no apparent object from morning until night with great spiritliness and animation, and so lightly do they move that they can glide round for a minute, it seems, without circles on its surface. Very fond of society; we seldom see them alone, or if parted by accident they soon rejoin their happy companions. One pool commonly affords space for a large antemias, yet they do not always consist of the family, but perform their circling motions in families or associations. If we interfere with their merriment they seem greatly alarmed, disperse or dive to the bottom, where their fears shortly subsist, as we soon again see our merry little friends gamboling as before. When they dive to the bottom of the water in the manner above described, they carry with them a little bubble of air affixed to the extremity of their bodies. Also they are sometimes to be found flying, their well-formed wings permitting such an operation, while the high polish of the body protects them from the action of the water. With the exception of a few exotic species, the insects of this family are of a small size, seldom exceeding a quarter of an inch in length; and the largest ones do not reach one inch. Some of the species are found on the margins of the ocean. They emit when touched a disagreeable scent, arising from a milky fluid which exudes from the different parts of the body, and which is not readily dispelled. The structure of the fore legs indicates their mode of life, serving as arms to convey the food, which they find floating upon the surface of the water, and which consists of small dead insects, &c., to the mouth. The number of species of this family does not exceed 60 or 60, and of these not more than eight or nine are found in this country; of these the Gymnura natator is the common one. It is of a brilliant bronze colour, with the sides of the body and antennae metallic; the margins of the elytra and legs reddish. The elytra are ornamented with lines of impressed spots. It is about a quarter of an inch in length.

the establishment of Sunday Schools, and other Christian efforts. In December 1797, the Society for propagating the Gospel at Home was instituted. In February 1799, Mr. James Haldane became the first pastor of the Tabernacle or Circus Church. In May 1801 the congregation removed to a new Tabernacle, built at the head of Leith Walk. The entire cost of Mr. Robert Haldane. In 1808 Mr. James Haldane having changed his views with respect to Infant Baptism, although he left the communion open to parties who might differ in their views of this question, many of the members of his church left. Mr. Haldane continued minister here till his death, which took place on the 8th of February 1851. Mr. Haldane published numerous pamphlets on subjects which at the time excited attention in the religious world, and his larger treatises may be found in his works on 'The Doctrine of the Atone-ment;' 'On Christian Union;' his 'Exposition of the Epistle to the Galatians;' and 'Views of Social Worship.' Some of his pamphlets were directed against the opinions of the Irvingites.

HALES OWEN, Worcestershire, a market-town and borough, in the parish of Hales Owen, is situate in 53° 32' N. lat., 2° 5' W. long., distant 36 miles S.E. by E. from the river Severn, and 26 miles N.W. by N. of Chester. The population of the borough of Hales Owen in 1851 was 3412. The living is a vicarage in the archdeaconry and diocese of Worcester.

The town of Hales Owen is pleasantly situated in a valley, and contains many good houses. The parish church is a fine building, with a handsome spire, supported by four arches. The Independents, Baptists, and Wesleyan Methodists have chapels. In Hales Owen are a Free School,
founded about 1852, which has an income of over 100L. a
year, and had 60 scholars in 1853; National Schools, and
an Infant School. Nails and hardware are extensively
made. The market-day is Monday; fairs are held on
Easter Monday and Whit-Monday. Some remains exist of
an abbey of Selmeston, and a church of Selmeston, both
in the reversion of the Kilmington. Near Hales Owen is
the Leasowes, the birthplace, the residence and
place of residence of the poet Shenstone, and the grounds
of which were arranged by him. Shenstone was, in
Hales Owen churchyard, and the church contains a monu-
ment.

Halesworth. [Suffolk.] Halibut, or holibut. [Hippolousus.]

Haloclasia (Fries), a genus of Plants belonging to the
natural order Umbellifera, and the tribe Sacesene. It has
a compound leaf, with a petiole, a leaflet, and an
infixed lobe and short claw; the fruit elliptical, terete,
or slightly dorsally compressed; carpels with five sharp
somewhat winged ridges; interstices and commissure with
many villosity, not cohering to the seed, without vittae.

One species of this genus is a native of Great Britain.

H. Scoticum, Scottish Losey, is found on rocks on the
coast of Scotland and Northumberland. It has an her-
beacon stem, tinged with red, from 18 to 16 inches
high. H. Fasciculat. Haltwhistle. [Northumberland.]

Hamilton. [Canada, &c.] Hamilton, Sir William, as head of the old family
of the Hamiltons of Preston, in Haddingtonshire, inherited a
title of Lord Preston, in 1763, but for some time remained
without issue. He was born on the 8th of March, 1778, in Glasgow, where his
father, Dr. Hamilton, was a professor in the university; and
there he received the earlier part of his academical education.
The Snell foundation of exhibitions at Balliol College, has
long been a prize for the more distinguished among the
Glasgow students: Adam Smith, among others, owed his English education to it. As a Snell exhibitioner Hamilton
went to Oxford; and he took his degree with honours as a first-class man, in 1801, or 1802. 
In 1813 he was admitted a member of the Scottish bar.
But law, except the Roman, did not receive much of his
attention; and the only practice he ever had was the very
little which became incumbent on him, when, after a time,
he was appointed aウンior solicitor of solicitors. Even
while a very young man, he had acquired no small part of
his singular and varied stock of knowledge; and mental
philosophy began early to be his favourite pursuit. On
the death of Thomas Brown, in 1820 he stood for the professor-
ship of Moral Philosophy in the University of Edinburgh:
but Mr. Wilson was the successful candidate. Next year,
on the nomination of the bar, he became Professor of
University History in the same university. This appointment,
little more than a year in the enjoyment of; in respect of the
independence, was hardly better to the performance of duty. The depart-
ment is not in any way imperative on students: and it never
commanded pupils, unless for a while under the elder Tytler.
Sir William Hamilton, however, was appointed to it,
chiefly from a sense of his inability to do justice to the
professional drudgery, was left undisturbed and undisturbed,
to the prosecution of his studies and speculations. It was long
before these bore fruits visible to any but his immediate
friends. For the digesting of his thoughts he was nearly as
independent of the necessity of writing, as his iron memory
made him to be for the preservation of his knowledge; and
he seems to have long shrunk from the toil of endeavoring
to expand ideas, for which he did not hope to find an
easy or popular audience. It was only, as he himself
decided to the reading of the editor of the Edinburgh Review,
that he was induced, in 1839, to give to
that periodical the first of a series of contributions, which
closed in 1839, and which unfortunately constitutes as yet
by far the larger proportion of all his published writings.
Those papers exhibit the variety of his learning not less than
its depth; and the philosophical essays which were among
them speedily found readers, who, if few, were competent
to do justice to their excellence.

In 1836 he found his right place: he was appointed by
the town council of Edinburgh, though not without a con-
test, to be Professor of Logic and Metaphysics in the Uni-
versity. He was, what very few of the Scottish professors
have been, an object of admiration, and a model of both
the spheres indicated by the official title. The vague term
which stands second, opened up to him in his teaching any
walk he might choose to tread in the vast field of mental
philosophy, of which he had probably in his studies traversed
more than any other man then or now alive. The first title
pointed his way to one special mental science, which he had
studied in all its existing shapes, and which he now set about
systematizing in harmony with new lights that had dawned
on his own science. The teaching of the mental and official
practice, of combining the whole matter of his instruction
into one course of lectures, to be delivered in one and
the same session (a term of six months in each year), he lectured
alternately in the one named section and in the other— in
London, but for a large part of the year, in Edinburgh.

His reputation and influence now extended rapidly. Lecturers and philosophers
put their heads together, and circles of Germany, and had been to know and esti-
ated by many at home: the most eminent foreign thinkers
had concurred with not a few of our own, in pressing sar-
very soon, likewise, after that year, his health began
to fail; and paralysis struck the right side of his body from head
to foot. He was for a time utterly disabled from teaching, and
was afterwards able to lecture only with frequent assistance.
But the vigour, both of intellect and of will, was un-
paired as it had been with Dugald Stewart under a similar
calamity. His reading and thinking were still carried on;
even his writing was so, not without very much aid from
others. That more of his large designs were not executed,
was not because they were not sufficiently supported, but
because they were too ambitious, and too tedious, and too
on the one hand, and on the other to newer ones, especially
Hamilton's own metaphysical doctrines—doctrines which he
himself always regarded, and firmly and thankfully re-
spected, as having their essential germ and foundation in Reid,
and as being merely a development of the common sense
philosophy to results made possible by a combination of
scholastic and German methods. Sir William Hamilton's
annotated edition of 'The Works of Dr. Thomas Reid'
appeared in 1846, much of it having been begun a few
years before. But for the sake of the existing works for this date (1852)
leaves it lamentably incomplete. On not a few problems
deep interest—on not a few also bearing closely on our
comprehension of Hamilton's own system of thought, we
are left with references and foot-notes to 'the numerous dis-
ventions, of which not a word is yet given us; and a dissertation
asserting his own peculiar theory of the Association of ideas
is broken off abruptly at the end of the volume. In 1852
appeared the first edition of a reprint, with notes, of
'his Metaphysical Discourses—Discourses on Philosophy and
Literature, Education and University Reform—chiefly
from the Edinburgh Review.' Translations of several of the
essays had previously been made into French, Italian,
and German, and are well worth a place among the
particularly valuable. Sir William's regard for the Scottish school
in philosophy next showed itself, not (unluckily) in the completion of his 'Reid,' and those farther developments of

Digitalized by Google
his own doctrines which he had there promised, but in a
tribute to the memory to another of its celebrated masters, from
whom he had neither derived, nor professed to derive, much
if anything in his own opinions. He undertook to
cite, with notes, the collected works of Dugald Stewart.
The publication, begun in 1804, is still uncompleted; and
nothing has been added to it, which he considered
formerly it. In 1805, when in country-quarters, Sir William
suffered fracture of a limb; and he died in Edinburgh on
the 6th of May, 1856. He has left a widow and family.

The romantic rationalism of the day required it, as
nothing else to be in such a state, that they may easily be prepared
for the press.

As those who knew Sir William Hamilton through his writings only, cannot do full justice to the multifariousness of
the aspects of his genius, and the ripeness of his mind, a few
lines which his writings which had personal bearings, will do positive injustice to the real likableness of his personal character.

He was undoubtedly a stern, and keen, and often eager controver-
sialist, occasionally even a hasty one; in debate he never beat about for smooth words; and, absorbed in his
love for science and learning, he sometimes forgot to be
gentle towards those whom he thought to be erring or knew
to be comparatively ignorant. He was watchfully jealous also, of what he considered an inadequate preparation of
his elders in the art of writing. Under the influence of the
combative tendency, moreover, there lay great generosity,
great kindliness and warmth of heart: he was invariably
amiable when occasion did not force on polemics: he was an
active and steady friend, beloved as well as esteemed by
those who were associated with him by literary ties. About
his erudition there cannot well be two opinions among
those who have had opportunities and competency for judging. Its mere mass was a thing extraordinary: it was a
manifest demonstration of accurate scholarship; it spread over tracts of reading
the most obscure and neglected; and it was, everywhere, the
real knowledge of a thinking man, not the word-cramming
of a pedant. His range embraced all the great divisions of
knowledge, except mathematics and physical science; while
here, too, it did not exclude anatomy, with physiology and
some other branches of medicine. He was a thorough
linguist in the classical tongues, and in German. With
as little as possible of the poetical temperament, he was well
versed in the ingenious theories of his German colleagues, unusually
extensive. In philosophy he was familiar with the
Greek writers one and all: Aristotle and his commentaries he probably studied more extensively and profoundly than
any modern reader; and he was the only man in the
whole age who knew the whole course of the scholastic philosophy, as
no man else has ever known it since the middle ages departed.

With British systems it is needless to say that he was
familiar in all directions; and he was the only man among
the circle near to having studied—and nowhere either
carelessly or at second-hand—all the German systems that
have emerged or diverged from that of Kant.

As to his originality, this question may be put: not whether
Hamilton was the most original of philosophers; but whether
there has ever been any philosopher who, to learning even
half as great as his, united so much of real and active
originality as a thinker. In his treatment of details he has
a favourite manner, which often disguises his independence. His
reasoning and mode of argumentation, as if the best way of
discerning philosophical truths was by decyphering them in
some medieval text through the dust of centuries. He takes a pride in quietly fathering on some
scholman or other a doctrine or an argument which many
may have been too glad to take for themselves.

The outlines, however, of those sections in his own
philosophical creed which he has taken the trouble to
expose, are laid down broadly enough to let their character
be seen clearly. Be his leading doctrines held true or false,
with no respectability attached to them, he was the
ministry for the production of a philosophical
originality, and in his own as very many systems which all of us rightly admit to
be essentially novel,—as much his own, it may be said, as
any system of philosophical opinions can be, unless it ignores
everything that great thinkers have ever thought before.

What may be the correctness, and what the value, of his
peculiar opinions, is a question on which, if it were to be
adjudged at present, contradictory verdicts would be given.

Probably no one will be competent to decide it justly, till
there has been some considerable time for the test of the
facts, which will at last be given to the world. Not
merely the probability, but something like the certitude,
which travel in a track, not only at several points
new in itself, but likewise, everywhere, little familiar to
most thinkers in this century. Hamilton's writers are Ger-
man; his mind is that of a German mind. He is
indeed, with which he has taken German doctrines and methods
(with a large admixture of Scholasticism) as materials to
be distilled in his own alembic. The exotic character is observable,
both in his highly speculative aims, and in his severe
exhaustion of the sources of philosophy. German
characteristics is distinctively alien to the broadly practical English
mind; and the latter is one which has never, before him at
least, been made to take root in the philosophic mind of
Scotland. Nor can his writings be mastered without pains.
He never cares for doing more than saying what he thinks to
be worth saying—saying it unequivocally, and saying it in
the smallest number of words that is consistent with safety.
He will not turn aside to amuse us; he will not hurry or
wavering as a hard master to his exercise. He is a
precise, dry, writer. But for such as will take the trouble

Of Hamilton's Psychological and Metaphysical doctrines, nothing special requires to be said.
They are before us, in certain parts, in his own exposition; and that they have already
been much discussed, and have come under various exacting
powerful influence on speculation, is a good omen for
philosophy. We have, especially, his treatment of three great
problems in philosophy. First, there is his theory of the
unlimited: two kinds of knowledge, complete and
ephemeral. Secondly, there is a special application of this theory to
the construction of a theory of External Perception. Thirdly,
there is an exhaustive system of Metaphysics Proper, or
Ontology, in his 'Philosophy of the Conditioned,' or 'Conditions of
the Thinkable'—a vast and noble idea, traced out for us,
as yet, in nothing but a tantalising fragment.

Regarding his Logical system, our public information is
still very unsatisfactory. It is to be gathered from an appendix
to his 'Discussions,' and an authorised but unguaranteed
publication from lectures, Bayes's 'New Analytica.' The materials
will probably convey no distinct notion of the system,

Instead of recognising only four forms of propositions, the A, E, I, O, of the old
logicians, he insists on
admitting all the eight forms which are possible.
(See Thomson and Salley.)

He widens the range of the syllogism, by admitting all moods which can validly be constructed
by any combination of any of his eight kinds of propositions.

4. The Port-Royal doctrine, of the inverse ratio of the
expansion and contraction of time, is elaborated
in its reference to the syllogism. This application of the
doctrine has certainly not been anticipated by any logician.

Hämmer-Pürostall, Joseph, Baron Von, was
born in 1774 at Grätz in Styria, where his father held a
respectable post under the Austrian government. He was
educated at the University of Vienna and received his
degree in 1796 from the University of Oxford, an academy established by Prince Kaunitz.

After having taken a
part in the compilation of Meminsk's Arabic, Persian,
and Turkish Lexicon, he was appointed in 1796 secretary to the
Baron von Jesiisch, the reporter to the Oriental section in the

1849, he translated a Turkish poem on the Last Judgment, and
supplied several other poems to Wieland's 'Deutscher Mercur.' In
1798 he was attached to the embassy of the learned Baron von Herbst at Constantinople, who sent him with one of the imperial consuls on an important errand to Egypt, where he procured for the imperial library some mummies of the ibis, hieroglyphic lamps, a number of mummies, and other rarities. As interpreter and secretary he made the campaign in Egypt under Hutchinson, Sir Sidney Smith, and Joseph Facha, against Menou, and in the autumn of 1801 proceeded by Malta and Gibraltar to England. He arrived at Harburg on the 20th of November 1801 accompanied, in August, the Austrian ambassador, the Baron von Stürmer, as secretary of legation to Constantinople. In 1806 he was appointed consular-agent in Moldavia. In 1807 he returned to Vienna; in 1812 he was a state councillor, and in 1817 a minister of foreign affairs. In 1818 he succeeded to the estate of the Countess von Purgstall. In 1815 he had occupied himself earnestly in procuring the restoration of the Oriental manuscripts and other treasures, which had been removed from the Vienna library to Paris by Denon, during the occupation of Vienna by the French in 1809. In 1847, continuing to be in the active service of the department of foreign affairs as councillor extraordinary, he was chosen president of the newly instituted academy, which he resigned after holding the office for two years. His intervals of leisure from business were spent at his castle of Hainfeld in Styria, where he laboured on his very numerous literary and historical works, on which he died on the 11th of August, 1855. His works are extremely numerous, and those of a historical character highly valuable. His publications of Turkish, Arabian, and Persian poems are in many instances interesting to the general reader, but his philological knowledge was not sufficient to make him a reliable translator to the student. Among the more noticeable of his historical works are: 'The Trumpet of the Holy War,' 1806; 'The Constitution and Government of the Ottoman State,' 1816; 'Dances upon a Journey in 1804, from Constantinople to Broussa and Olympus, and thence back byNicma and Nicomedia,' 1818; 'History of the Assassins, from Eastern Sources,' 1818, a work which has been translated into English by Mr. Wood; 'Constantinople and the Bosphorus, topographically depicted by drawings, arab., pers., turk., bibliotheca cases,' 1822; 'History of the Ottoman Empire,' in ten volumes, 1837-1834, an excellent work, of which several editions have been published; 'The Government under the Khilifa,' 1835; 'Picture Gallery of the great Musulman Commanders, with Memoirs,' in six volumes, 1837-39; 'History of the Golden Horde of Kiptchak, that is, of the Mongols in Russia,' 1840; 'History of the Ilkhan, that is, of the Mongols in Persia,' 1842-44. All these works give a definition of the political state and present state of the East. Of his other productions we may mention, 'Schrin,' a Persian poem, 1806; his translation of the 'Divan,' of Hafi, from the Persian, 1813; his 'History of the Literature of Persia, with Specimens from 700 Poets,' from Persian, Turco-Mongol, Slav, Arabian, and Turkish sources, 1818; 'The String of Jewels,' from Abul-Maazia, 1823; a translation of the Arabic lyrical poet Motzemebi, 1823; a translation from the lyrical poems of Baki, 1835; a 'History of Turkish Poetry,' with selections from 2000 poetical works; Faist's allegorical Turkish Epic of the Rose and Nightingale, 1834; Samsachari's Arabic poem of the Golden Necklace, 1835; Mahmud Scheibistere's didactic poem on Sulfism, entitled the 'Rose-Bloom of Secrets,' 1836; the 'Turkey and Turkish didactic and historical works; 1840; and a 'History of Arabian Literature,' in three vols. 1850-52. He has also written a volume 'Mungan's Drink-pong,' (Mungan's Triad), containing an Indian pastoral, a Persian song, and a Hindu comedy. For his translations of the 'Contemplations of Marcus Aurelius' into Persian, published in 1831, he was rewarded by the Shah with the order of the Sun and Lion. In 1810 he established a periodical work 'Miners of the Orient,' to which he contributed many essays on ancient and modern Arabia, and a 'History of Persia,' which was continued till 1816; and he was a frequent contributor to the 'Jahrhüben für Literatur' ('Year-Books for Literature'), and to other periodical works, H.A.B. [Von Vorwacht] and H.A.B. [Von Vorwacht].

HAB. [Habran, S. J.]

HABURG, a sea-port town is the kingdom of Hanover, province of Lüneburg, is situated on the left bank of the southern arm of the Elbe, opposite Hamburg, 106 miles by railway N. from the city of Hanover, and has about 9000 inhabitants. It is surrounded by walls, and defended by a citadel, which also commands the passage of the Elbe. There are two churches, an hospital, a gunpowder factory, sugar refineries, tanneries, manufactories of woolen stuffs, lines, and mercantile houses. It was of ancient foundation, and was possessed by the Danish, and afterwards by the Electors of Saxony, and is situated between the countries south of the Elbe. The timber trade of Hamburg also is extensive. A steam-ferry affords frequent and rapid communication with Hamburg. As sea-going vessels could not formerly be brought alongside the quays, goods were landed by means of small boats called 'scheffen,' from a port near Hamburg, and enlarged so as to afford accommodation for 500 vessels, which may now land their cargoes on the wharfs. The depth of the channel between Harburg and Altona is 10 feet at low and 15 feet at high water. The port extends to the railway goods-station, and mercantile vessels. Altona is a large and busy port, and consists of 500 acres of land, and the hold of vessels and placed on the train. The improvement of the harbour, the completion of the railway, and the declaration of the freedom of the harbour in 1850, gave a great impetus to the commerce of Hamburg, which still continues to improve, although the freedom of the port was suppressed in 1853 by the commercial treaty with Austria and Prussia. The distance to Hamburg across the Elbe is four miles and a half.

HARDINGE, HENRY, VICOUNT, third son of the late Lord H. (born 1801), was educated at Harrow, and at the University of Durham, by Frances, daughter of James Best, Esq., of Chatham, was born at Wrotham, Kent, on the 30th of March, 1785. He was a member of a family which has long been seated at King's Newton Hall, Derbyshire, and is said to have been of the old Saxon shire of Deorulf." Having spent a short time at Eton, Henry Hardinge was gazetted ensign in a regiment of foot, October 8, 1798, obtained his lieutenancy in 1802, and captaincy in 1804. It was his good fortune to be posted to the 95th, which won the battle of Waterford, then Sir Arthur Wellesley, under whom he served throughout the whole of the Peninsular War, and for a considerable time was upon the staff of the commander-in-chief; he was also for nearly the entire period deputy-chief of staff, and was at the battle of Novi. He was present at the battles of Roli and Vimiera, where he was severely wounded; at the battle of Corunna he was by the side of the gallant Sir John Moore when he received his fatal wound. After having lost his friend at Corunna, he was present at the passage of the line of the battle of Buiscos, the lines of Torr Vedras, and the battle of Albuera. In this engagement he displayed the greatest skill, courage, and self-command; it was a hard-fought field, and to the change in the ground was largely due the final defeat of the army. The value of the British infantry, Lord Hardinge often pointed back in after life as having encouraged him as a general to persevere through every obstacle, and to place perfect confidence in the enduring valour of British troops. After the battle of Vitoria in 1813 he was one of the commanders of every engagement of the war. He took part in the first and second sieges of Badajos, at Salamanca, and at Vitoria, where he was again severely wounded, and also at Pampeiana, at the battles of Las Poyenes, and at Nivelle, Nive, and Orthes. When he returned to England after the close of the Peninsular War, he was justly regarded as one of the most gallant officers in the service. Upon the renewal of hostilities he was again in arms, and took an active part in the operations preceding the battle of the Pyrenees on October 9, 1813, whose staff he then was serving. Two days before the battle of Waterloo he was employed as a brigadier-general with the Prussian army at Ligny, where, in a skirmish with the enemy, he was wounded in the left arm, which had to be amputated immediately, and prevented him from taking a personal part in that glorious victory. He was however rewarded with the dignity of K.C.B. on the enlargement of the order of the Bath in the same year, and with a pension of 2000 a year. He died at his palace of Wesselton, near the coast of Russia.

When upon the resignation of Lord Goderich, in 1829, the Duke of Wellington undertook the construction of a ministry, he chose Sir Henry Hardinge (who had been returned as member for Durham in 1820 and again in 1826), to succeed Lord Grey. He was subsequently made a privy counsellor, and a member of the privy council, and two years later exchanged this position for that of the chief secretarieship for Ireland, under the late Duke of Northumberland as lord lieutenant. Here however he did not remain long; the Duke's ministry
retired from office in the autumn of the same year, and Sir Henry Hardinge returned to England. He resumed his high post however under the short-lived ministry of the late Sir Robert Peel, which lasted from November 1834 to April 1835. From this time till the return of Sir Robert Peel to power in September 1841, Sir Henry Hardinge remained in office. At the commencement of the Crimean war, the directors of the East India Company thought that the time had come when it was necessary for them to recall Lord Ellenborough from the high post of governor-general of India. It was stated by Sir Robert Peel in his place in the House of Commons, that when the Russian invasion of the Crimea, and the Home Government were at issue as to the propriety of this step, they were quite of one mind as to the selection of his successor; and that when the premier recommended Sir Henry for the vacant post, on the ground of his great experiences of civil matters, his high personal character, and his military eminence, the chairman of the company answered that his own choice had already fixed upon the same individual.

In 1844 he accordingly undertook the government of India, and was sworn into office on landing at Calcutta in the July following. On his arrival he found the vast territories under British rule enjoying the most profound peace. The disasters of the Afghan campaign had been averted; Sir Harry Outram had been killed at the battle of Scinde at Measoe and Hyderabad; Scinde itself had been annexed to our dominions; and the Mahrrata war had been terminated by the submission of the Durbar at Gwalior. The governor-general had therefore ample time to make himself master of very many details of government, in which he was not slow to perceive that considerable reforms were needed. Able and indefatigable in his efforts, he did his best to bring about a better feeling and a more friendly footing than had hitherto existed between the rulers of the Company and the claims of the natives to many privileges; he promoted a stricter discipline among the troops in general; he lent his powerful aid to the organisation of those Indian railways which have since been carried out with such marked success under his successor Lord Dalhousie; and in short, he did all that was in his power to promote the welfare of the community at large.

But the course of Indian events was not long destined to flow on in peace. A storm of war and bloodshed was gathering, and Sir Henry Hardinge, with all his powers, could not have foreseen or avoided the events which awaited him. The death of Ranjeet Singh, the Lion of Lahore, had paved the way for an infinity of plantings and combinations, both of the British and the native dominion. Since the death of the Lion, it seemed that the controlling power had left Lahore; the young maharaja, Dhunleep Singh, a child of four years old, was, together with his mother, in the hands of the Sikh soldiery, who were weary of domestic faction, and clamoured to be led against their English neighbours. Active preparations were made by the Sikhs for crossing the Sutlej; but long before the public had any idea of what was going on, Sir Henry Hardinge was on the alert, and had quietly concentrated a body of 32,000 men and guns round Feroepore, Looodianah, and Umballa. The governor-general reached the latter place about the middle of December, and, proceeding to Looodianah, inspected the various cantonments, and made himself acquainted with the system of defence. He then went up the whole of his force from Umballa; and on the 13th, learning that a large Sikh force had crossed the Sutlej river, he issued a proclamation against the hostile invasion. On the 17th the Sikhs advanced, and partly entrapped themselves within strong earthworks at Feroepore, while the other part encamped near Moodkee, opposite Feroepore. The combined operations of the British cavalry under Brigadiers Gough, White, and Mactier, and the infantry under Sir Henry Hardinge and his brother, who was acting as colonel of the 1st annum, and General Lilley, drove back the Sikhs from their well-contested position, and won the glorious victory of Moodkee—a victory too dearly purchased by the death of Sir Robert Sale. On the 22nd the attack was renewed at Feroepore; but no results were obtained, and on the 26th the Sikhs in some Sikh guns were being brought to bear with deadly aim upon the British columns, when the governor-general mounted his horse, and at the head of the 80th regiment, and a portion of the 9th European, carried the guns at a charge, and spiked them. The main force of the Sikhs, which had been carried by the bayonet, the enemy’s guns were captured, and the invaders recrossed the Sutlej. The want of cavalry alone prevented Sir Hugh Gough from following the enemy and completely destroying him.

There is something truly touching in the fact that, in this important battle, Sir Henry Hardinge, though he held the supreme civil authority in India, offered his services to Sir Harry Outram to take an active part in the eventful scenes of this and the following day, in the pursuit of the left wing of the army throughout. The Sikhs, again defeated at Sobors and Ailival, were forced to sue for terms; and the treaty of Lahore, concluded by Sir Henry Hardinge, the 15th of April, 1846, went so far as to give a nameless conqueror. He exacted from the Sikhs the whole expense of the war, and left a British Garrison, under the late Sir John Littler, in Lahore, the capital of the Panjab, for the protection of the maharaja’s authority. This country—a healthy, well watered, and fertile region—was consequently annexed to our dominions by the Marquis of Dalhousie. On the ratification of this treaty, Sir Henry Hardinge received the thanks of both Houses of Parliament, and the title of lord was conferred upon him. He was advanced to the peerage as Viscount Hardinge of Lahore. The East India Company also conferred on him a further pension of 5000 l. a year; and the city of London voted him their freedom. In January 1846 he was succeeded in the Indian government by Lord Dalhousie, and the Sikhs, by the principle of Tory principles, after his elevation to the peerage Lord Hardinge rarely spoke or biased himself in the House of Lords on any measures except those of military interest.

On Lord Derby’s advent to power in February, 1846, Lord Hardinge again to England as master-general of the ordinance, and succeeded to the post of commander-in-chief, on the death of the Duke of Wellington, in the September following. He obtained the colonelcy of the 71st Foot in 1846, and was promoted to the dignity of G.C.B. in 1848 on foreign orders, he received those of the Red Eagle of Prussia, Wilhelm of the Netherlands, the Tower and Sword of Portugal, and that of San Fernando of Spain. He also received a cross and five clasps for his Peninsula services, and was present in no less than sixteen general actions for which medals were granted. He was promoted to the rank of Field-Marshall on the 2d of October, 1855. He resigned the office of commander-in-chief in consequence of a paralytic seizure, in July 1856. In the administration of the Home Guards, and veteran discipline of the Duke of Wellington, Lord Hardinge trode most carefully and religiously in his Grace’s steps. In 1851 he married the Lady Emily Jane Stewart, daughter of Robert, first marquis of Londonderry, and widow of the late Admiral Sir Henry Hardinge, and daughter and two sons. The younger son, Arthur, now captain and lieutenant in the Coldstream Guards, was aide-de-camp to his father in the battles on the Sutlej, and was also present at Alma. His lordship died September 24, 1856, and was succeeded by his eldest son, Charles Stewart, born in 1828, who had been private secretary to his father while governor-general of India.

HARE, JULIUS CHARLES, a distinguished English divine and controversialist, was born in 1796, and was one of the sons of the Rev. Robert Hare, rector of Hurstmonceux and vicar of Nissenfield in Sussex, who was the son of Dr. Francis Hare, bishop of Chichester. He was educated at Trinity College, Cambridge, and graduated B.A. 1816, and M.A. 1819. In 1822 he was instituted to the rectory of Hurstmonceux (a living belonging to his family); in 1840 he was appointed Archdeacon of Lewes; in 1861 he became one of the prebendaries of Chichester Cathedral, and from this year to his death, which took place in 1879, he was the great-grandson of the last of the family of Majesties’s chaplains. He died at Hurstmonceux on the 33rd of January, 1855. Such are the principal external facts in the life of a man whose personal influence in his day was so great, and whose works so important in our literature. His first literary appearance of any note was in 1837 when, in conjunction with a younger brother (the Rev. Angus William Hare, M.A., of New College, Oxford, and rector of Allton Barnes, Wilts, who died in 1834), he published a series of anonymous pamphlets entitled 'Questions at Truth, by Two Brothers.' Subsequent and enlarged editions of this work have been pub-
lished; and also a 'Second Series' under the same title). In 1828, in conjunction with the Rev. C. Thrilwall, afterward Sir, Mr. H. appeared as translator of the first two volumes of 'Niebuhr's History of Rome,' from the German. Of his subsequent publications, the following are the most important:—The Children of Light: a Sermon, 1838; 'A Vindication of Niebuhr's History of Rome,' in the 'Literary World,' 1839; 'Sermons preached before the University of Cambridge,' 1839; 'The Victory of Faith, and other Sermons,' 1840; 'The Better Prospects of the Church: a Charge to the Clergy of the Diocese of Sodor and Man,' 1843; 'The Church: a Sermon,' 1845; 'The Mission of the Comforter, and other Sermons,' 2 vols., 1846; 'The Meas...
city on the 7th of July at the head of a column of about 1900 Europeans and Sikhs to retake Cawnpore. The garrison had been treacherously massacred after surrendering on terms, and where some of the women and children were still in the enemy's hands. He had to force his way through terrible odds, but he made good his ground, and on the 16th of July he defeated and destroyed a force of about 5,000 mutinous sepoys—his own force being 1000 Europeans and about 300 Sikhs. On the 17th he entered Cawnpore, too late notwithstanding all that he and his noble army did to save their unhappy countrymen, yet he led in the event an almost irresistible advance, and actions against overwhelming odds. Hardly waiting to give rest to his men, or to pay the last rites of sepulture to the mangled corpses of those who had been vilely murdered in Cawnpore, he took the field again on the 19th of July he again inflicted a severe defeat on the mutineers, and finding that Nana Sahib had evacuated his stronghold of Bitbor, renewed his march. But he had to fight at every step, stout fortresses had to be captured, and at length after, on the 16th of August, achieving his ninth victory over six times his own numbers, he found his road so reduced by death, wounds, and sickness, as to render it imperative on him, after almost coming within sight of the British defences, to make an arrangement to recall to England without being able to communicate cheering words to the besieged. Being strengthened by the arrival of General Neill with a small additional force, and joined by his old commander, General Sir James Outram, Havelock at the head of a force of 3000, crossed the Ganges on the 19th of September. Sir James Outram—one of the best and bravest of the many officers who have achieved eminence in India—would of course, as the superior in rank, in the usual order of things, supersede Havelock as commander, but with the generous charity of a true-hearted warrior, he in an order of the day announced to the army that "in gratitude for and admiration of the brilliant deeds in arms achieved by General Havelock and his gallant troops," he would "continue to order the force to Lucknow in his civil capacity as chief commissioner of Oude, tendering his military services to General Havelock as a volunteer." On the 21st of September the fortified position at Meeranhour was forced; on the 25th Lucknow was reached, and the garrison, which had been blockaded for nearly four months, relieved, just as it had been mined and was ready to be blown up by the besiegers. The following day the intramurals of the enemy were stormed, though with great loss, including that of the gallant General Neill.

On the 17th of November, Sir Colin Campbell, after four days' operations and some very severe fighting, forced his way into the residency at Lucknow, and the garrison was relieved and allowed to form up in the fortresses of Alambagh, near Lucknow, on the 4th of November, 1857.

We need hardly add that the splendid march of Havelock on Cawnpore and the relief of Lucknow have not merely rendered him the popular hero of the Indian war, but added new glories to the British arms. As a reward for his eminent services he was created (Sept. 1857) a Major-General in the army, his promotion bearing date July 30, 1857, made a Baronet, and raised to be a Knight-Commander of the Bath, and, in accordance with a royal warrant, was elected a Fellow of the Royal Society. He was now 40 years of age, and had spent 19 years in the service, 5 of which were at home, 2 at Cawnpore, and 12 at Lucknow. He had now accomplished a great work, and was in full possession of the highest honours that a soldier can aim at. His reputation was established; and, with the promise of a bright future, he was allowed to return to England to be present at the marriages of his sons.

HAYDON'S CANALS. [Tintines, Organo, &c.] HAWK-MOTH. [Springside.]

HAYDON, BENJAMIN ROBERT, was born January 22d 1786 at Plymouth, where his father was a bookseller. Haydon was educated at the public schools at Plymouth, and afterwards at the Plymouth grammar-school, where Sir Joshua Reynolds had received his education. Haydon's father drew a little himself, and had a taste for art, and was delighted to see his son turn to painting. He was, indeed, there was no other son, to adopt his business, and Benjamin was accordingly apprenticed. But the youth hated the business, and expressed his resolution to become a painter so determinedly, that after much opposition his father consented to his scheme. On leaving his father's house, his Prince Flore, a friend of the family, got him introductions to Northcote and Opie, and afterwards to Fuseli, keeper of the Royal Academy, by whom he was readily admitted as a pupil. He was a student at the studio of Fuseli; and, at the age of eighteen, an enthusiast for Raphael, Inchbold, and high art, Benjamin Haydon commenced his career. Here he drew with great earnestness, and soon acquired great readiness of hand. He also spent much time in dissecting and the study of anatomy, and was able to produce a very fine amount of knowledge. But his studies were too desultory and interrupted, and there could be little doubt that the weakness of his eye—he had while a youth been for a short time quite blind—was a great hindrance to successful study in this point of view. With form and chiaroscuro he succeeded, and others subsequently famous, were his fellow-pupils, yet he seems to have been generally regarded as one of the most promising students in the institution, while he was a great favorite with the masters.

Haydon exhibited his first picture at the Royal Academy in 1807. The title alone will show the daring of the young painter, "Joseph and Mary resting with our Saviour after a day's journey on the road to Egypt." Mr. Hope, author of "Antiquities," became the purchaser of this picture. The reputation which the artist gained by it gave him increased energy and ambition. "Dentatus" was the subject chosen by him next year; and from this period Haydon dates the commence ment of the union between the English and the Royal Academy, whom he accused of illiberality on every point, and who retorted with "Dentatus" where it could not be seen, and of a fear of historical painting as the cause of their refusal to admit him as an associate, while they admitted less skilful artists. The purchase of "Dentatus" by Lord Molyneux in the following year was exhibited in the British Institution, where it received the praises of the public, and the prize of the committee. About this time the Elgin Marbles were first exhibited in London, and Haydon's enthusiasm about them was unbounded. He painted Sir William traces, a historical picture, and in 1812. His "Venus and Anchises" were purchased by Lord Molyneux for 400 guineas; his "Alexander returning in triumph, after vanquishing Bucephalus," found a purchaser at 500 guineas in the Earl of Egremont; and his "Venus and Anchises" was purchased by Lord Talbot for 500 guineas. Haydon now got diverted from steady and constant application to painting by his fondness for controversy; and the attacks he published on the Royal Academy, by estranging him from some personal friends among artists and the patrons of art, greatly exasperated his temper, and there can be little doubt produced a lasting ill effect on his fortunes. From this time his life was to a great extent one of strife, and of constant struggle with pecuniary difficulties. Still he was at no time without friends. Sir G. Beaumont gave him a commission for a subject from Maccaboth, a 'Judgment of Solomon' was bought by Mr. Ellford and Mr. Tingcomb for 400 guineas; his 'Alexander returning in triumph, after vanquishing Bucephalus,' found a purchaser at 500 guineas in the Earl of Egremont; and his 'Venus and Anchises' was purchased by Lord Talbot for 500 guineas. Haydon now got diverted from steady and constant application to painting by his fondness for controversy; and the attacks he published on the Royal Academy, by estranging him from some personal friends among artists and the patrons of art, greatly exasperated his temper, and there can be little doubt produced a lasting ill effect on his fortunes. From this time his life was to a great extent one of strife, and of constant struggle with pecuniary difficulties. Still he was at no time without friends. Sir G. Beaumont gave him a commission for a subject from Maccaboth, a 'Judgment of Solomon' was bought by Mr. Ellford and Mr. Tingcomb for 400 guineas; his 'Alexander returning in triumph, after vanquishing Bucephalus,' found a purchaser at 500 guineas in the Earl of Egremont; and his 'Venus and Anchises' was purchased by Lord Talbot for 500 guineas.

His next great work was 'Christ's Entry into Jerusalem,' began in 1814, but not exhibited till 1826, when it formed part of an exhibition of his own in Bond Street. The picture did not sell, but this did not prevent him from painting 'Christ in the Garden,' and 'Christ Rejected.' In May 1821 he married. His 'Raising of Lazarus' was painted in 1823. About 1815 he began to receive pupils, his first being the Landseers—Edwin, Charles, and Thomas—and his purpose being "to form a school, and to establish a better and more regular system of instruction than even the Academy offered." With many drawbacks he made a good teacher, and some of his pupils became distinguished. He sold his pupils, but he was ill fitted to carry on such an institution with the necessary regularity. He also became connected with Mr. Elmes in the conduct of the 'Annals of the Fine Arts,' and that publication became a vehicle for constant attacks by the Academy. Haydon retaliated as ably as possible by Mr. Elmes) on Haydon and his pupils. But the school could not so prosper, the writing brought in no money, and his painting, when not neglected, was not of a kind to attract the public. With a little encouragement he would have been an inmate of the King's Bench prison. Here he found a subject for a successful picture in the 'Mock Election,' which took place within those walls in July 1827. George IV purchased this work for 300 guineas. Haydon followed it with another for Lord Mountstuart, which was sold for 300 guineas to Mr. Francis of Exeter. He had previously regained his liberty with the assistance of Google Books
Haydon's next subjects, after making an unsuccessful attempt to obtain employment as a portrait painter, were 'The Great Banquet at Guildhall' at the passing of the Reform Bill, and 'Napoleon' at the Treaty of Tilsit. The former was considered a failure, but the latter met with great success. 'The Duke on the Field of Waterloo' fell far short of this, both in merit and public estimation. Again in 1818 he became a prisoner for debt in the King's Bench, but after a short imprisonment was able to subscribe the balms and moderate his expenditures. He now engaged with great zeal in lecturing on painting at various literary institutions in London and the provinces, and his lectures were everywhere attended with success.

The determination of the government to decorate the interior of the new houses of parliament with pictures opened a new and grand field before the imagination of Haydon. He had petitioned, written, and lectured in favour of adorning our public buildings, and impressed with a very high notion of his own capacity for executing such works, his sanguine temperament never permitted him for a moment to doubt that he would be one of the painters selected for the task. Accordingly, finding that his name was not in the favor with the board of the azure chapter, he determined himself to acquire mastery over the use of that material, and when the cartoon competition was summoned, he addressed himself eagerly to the preparation of a cartoon. The judges gave in their opinion in his favor; but he was forewarned that the successful competitors, even of the third class, was a death blow to all his hopes; and though he struggled bravely against the disappointment, he never really recovered the shock. His last works were 'Uziel and Siaton'; 'Currituck leading into the Gulf', 'Alfred and the Tyrolese', 'By Jove!', 'The Burning of Rome,' and numerous repetitions of his 'Napoleon.' 'Alfred,' and 'The Burning of Rome,' were exhibited in 1846 at the Egyptian Hall. The exhibition of 'The Death of Nelson' at St. Helens, and the extensive inquiries which his success excited, so incited Haydon's mind now entirely gave way under his misfortune. He died by his own hand, June 22, 1846. It should be added that a post mortem examination showed that there had been long standing disease of the brain. He left a wife and family, for whom a public subscription was immediately got up. It is not a little to the honor of Sir R. Peel, that, at what was perhaps the most busy and exciting period of his parliamentary career, he had found time just five days before the painter's unhappy death, to order the portrait of the painter from the impression of Haydon's 'Lectures' are almost his only contributions to literature. Considerable difference of opinion exists as to his merits as a painter. The exaggeration and hardness, which have been so much disapproved of his style, are ascribed to his early intimacy with and imitation of Fuseli; but unjustly; they are Haydon's own, the result partly of insufficient study, partly of incomplete artistic education, more of his peculiar physical temperament, and habit of working. But he had many merits, and he did much to raise the character of English art, and to extend an interest in and a love of it. For a fair and far from partial review of the character of Haydon as a man and an artist, the reader is referred to the concluding part of the third volume of Taylor's 'Life of Benjamin Robert Haydon,' 2nd ed., 5 vols., 1855. HAYNES. [MINN LIVE, S. J.]

HEAD, BIR GEORGE, Knight, was born in 1722, at the Hermitage, a few miles north from Rochester, in Kent. James Rooper Head, father of Sir George Head and Sir Francis Bond Head, was descended from Fernando Mendero, a Jew, who came from Portugal to England, and was physician to King Charles II. The father of James Rooper Head, married a daughter of the Rev. Sir Francis Head, Bart., of Ancaster, in Lincolnshire. George Head spent his early years at his father's residence, the Hermitage, and was afterwards educated at the Charter Houses School, London. Early in 1808 he obtained a commission to serve with the West Indies Militia and having obtained leave of absence, in the spring of 1809 he went to Portugal, where he accepted the humble situation of a commissariat clerk, and joined the British army under Lord Wellington at Badajoz. He was afterwards appointed to the commissariat department of a brigade. After Mamezen had retreated from the lines of Torres Vedras, and the battle of Fuente d'Onor had been fought, May 5, 1811, he was appointed deputy assistant commissary general, and attached to the army of the division of Sir Thomas Picton. In 1812 he was directed to proceed to Momento de Beira to establish the commissariat department of the third division under Sir Thomas Picton. He was present at most of the great battles in the Peninsula, as well as the concluding victory of the army under Sir John Moore at Salamanca. In 1814 he was in Canada in the North Social Department, and in 1818 there five years on the peace establishment. After his return to England he described his experiences and adventures in America in his 'Forest Scenes and Incidents in the Wilds of North America, being a Diary of a Winter's Route from Halifax to the Canadian Lakes, and in Four Months' Residence in the Woods on the Borders of Lakes Huron and Simcoe, by George Head, Esq.,' 2mo, London, 1819. In 1831 he received the knighthood of knighthood. Encouraged by the favourable reception of his works in London, he determined to tour through the Manufacturing Districts: also Memoirs of an Assistant-Commissary General, by Sir George Head, 12mo, 1837. The first Tour includes most of the large manufacturing towns in the northern part of England; the second, the island of Man, the lakes of Scotland, the Shannon, and part of Ireland. They contain a large amount of information carefully collected and clearly stated concerning the places visited and the manufactures carried on in them. Both Tours were published by the author, a Tour of Many Days.' He was also the author of several articles in the 'Quarterly Review,' and translated from the Italian the 'Historical Memoirs of Cardinal Foxos,' 2mo, 1800, and from the Latin, 'The Metamorphoses of Apollodorus,' 8vo, 1821. He died in London, May 2, 1855, unmarried.

HEADINGTON. [OXFORDSHIRE.]

HEALTH, PUBLIC. [PUBLIC HEALTH, S.]

HEART. One of the most interesting inquiries in connection with the human heart is that the presence of considerable light has been thrown by modern research. The circulating system is not perfected until the moment of birth; and in its several transitory stages of growth it resembles the guttae, or tiny blood-vessels, of the lower animals. As the egg of the bird affords the best means of studying these changes, we give an outline of them from Dr. Carpenter's 'Physiology':—

At an early period of incubation the yolks, or discs, are enveloped by a germinal membrane, composed of distinct cells, which is divisible into three layers; and a thickened portion of this is easily distinguishable, at which the embryo will subsequently evolve.

The middle layer gives origin to the circulating system, and is therefore termed the 'vascular layer.' The thickened portion of this that surrounds the germ soon becomes studded with numerous irregular points and marks of a dark yellow colour; and as incubation proceeds these points become more applied and finally elongate and form the heart-lungs, which are united together, first in small groups, and then into one net-work, so as to form what is called the 'vascular area.' A large dark spot of a similar kind is seen in the situation to be subsequently occupied by the heart. The dark spot in France, are formed by the collection of blood-corpuscles, which originate in the transformation of the cells of the embryo and of the germinal membrane; and the rows and masses of blood-discs seem at first to lie in many channels, the walls of the heart and blood-vessels that subsequently include them.

From the first however a definite plan is perceptible: the network of capillaries that is formed over the vascular area being supplied with blood by the ramifications of a pair of arterial trunks, whilst the blood is collected from the circular venous sinuses which bounds the area, and is re-
turned to the embryo by the various trunks. In the blood-vessels which are first observed in the body of the embryo, as well as in the vascular area, no difference is at first perceived between the characters of the arteries and those of the veins, and these are only to be distinguished by the direction of the currents of blood circulating through them.

But at about the fifth hour of incubation the costs of the arteries begin to appear thicker than those of the veins, and the distinction between them soon becomes evident. After the principal vessels are formed, the development of new ones takes place in the same manner, according as they are to occupy the interstices already occupied by previously formed, or are to extend themselves into out-growing parts. In the first of these cases the new capillaries appear to be formed, like the original ones, from stellate cells, which arise secondarily from a network of blood vessels already present, and which, as soon as they are formed, become continuous with the large vessels and receive the current into their own cavities, to transmit it to some other vessel. But in the second, the new vessels are formed entirely by extension from those already existing. This takes place in the following mode.—Suppose a line, or arch, of capillary vessels passing below the edge, or surface, of a part to which new material has been superadded; the vessel will at first present a slight dilatation in one, and coincident enlargements in the remaining vessels, but only when the edges yielded a little near the edge or surface. The slight pouch thus formed gradually extend, as blind canals, or verticula, from the original vessels still directing their course towards the edge or surface of the new material, and crowded with blood, as soon as it is formed, into this new stream. Still extending, they converge, and meet; the partition wall that is at first formed by the meeting of their closed ends clears away, and a perfect arch tube is formed, through which the blood, diverging from the main or former stream, and then following it, is being continually propelled. This last process may be seen in the growing parts of the tail of the tadpole, in the development of the filamentous gills and legs of the water-nat, in the first evolution of the extremities of the tadpole, and in the formation of new structures in the fully-developed organs, either for the repair of injuries or as the result of morbid processes. In some instances it would appear that the wall of the newly-forming vessel gives way, and that the blood-corpuscles escape from it into the parenchyma, at first collect- ing in an undefined mass, but soon manifesting a definite direction, and coming into connection with another portion of the arch, or with some adjacent vessel. Thus, then, a channel, and not a vessel is formed; and it is probably in this way that the arches and veins of fishes, as well as those of those vertebrates which have arches but no veins, are produced in many of the lower tribes of animals, and also, according to Mr. Paget, in some of the softer and least organised worms in man:

The origin of the heart appears about the 24th hour, and is a mass of cells, of which the innermost soon break down, so as to form a tubular vessel; for some time it is simple and undivided, extending however through nearly the whole length of the embryo; but the posterior part may be regarded as corresponding with the future atrium, since prolongations may be perceived extending from that part into the transparent area, which indicate the place where the veins subsequently enter. Although the development has proceeded thus far at about the 24th hour, no motion of fluid is seen in the heart or vessels until the forty or fifth hour. When the heart, which may be considered as analogous at this period to the dorsal vessel of the Annulida, first begins to pulsate, it contains only colourless fluid mixed with a few globules. A momentary flow of blood into the arches and veins of the vascular area is at the same time perceived; but this is independent of the contractions of the heart, and it is not until a subsequent period that such a communication is established between the heart and the distant vessels, that the dark fluid contained in the arches and veins of the vascular area is first propelled by its pulsations. This fact which we have just seen to possess a very important bearing on the theory of the circulation, and which has been denied by some observers, appears to have been positively established by the latest researches of M. v. Baer.

The contraction of this dorsal vessel (for so it may be termed) begins, as in the Annulida, at its posterior extremity, and gradually extends itself to the anterior; but between the 40th and 45th hours, a portion of the arch which is effected by a constriction round the middle of the tube; and the dilatation of the posterior portion becomes an aortic arch, and that of the anterior a ventricular cavity. Between the 50th and 60th hours the circulation in the vascular area becomes more vigorous, and the action of the ventricle is no longer continuous with that of the atrium, but seems to proceed at a separate period. At the same time the tube of the heart becomes more and more bent forward, so that it is thus much shorter relatively to the dimensions of the body, and is more confined to the portion of the trunk to which it is subsequently restricted. The convex side of the curve which the tube presents becomes the apex or point of the heart, and between the 50th and 60th hours this is seen to project forward from the breast of the embryo, much in the situation it subsequently occupies. About the same time the texture of the atricle differs considerably from that of the small vessels, becoming thinner and thinner, and membranous walls which it at first possessed; while the ventricle has become stronger and thicker, both its internal and external surfaces being marked by the interlacement of muscular fibres, as in the higher Molussae. About the 60th hour the grade of development of the heart may be regarded as corresponding with that of the fish, the atricle and ventricle being quite distinct, but their cavities are as yet quite single. The heart of the dog at the 21st day bears a great resemblance to the heart of the chick, for at the 60th hour; it consists of a membranous tube twisted on itself and divided into two principal cavities, besides the bulb or dilatation which at this period is found at the commencement of the sorts, and which corresponds with the bulbæ arteriosæ of fishes.

Having thus traced the evolution of the heart of the chick up to the grade which it presents in fishes, we may now inquire what is the condition of the other parts of the vascular system at the same time. At the end of the second day the primitive arterial trunk is seen to be divided into two canals, which separate from one another to inclose the pharynx, and then unite again to form the aortic trunk, which passes down the spine. During the first half hour of the third day a second pair of arches is formed, which encompases the pharynx in the manner described; and at the end of the third day two other pairs of vascular arches are formed, so that the pharynx is now encompassed by four pairs of vessels, which unite again to supply the general circulation. These evidently correspond with the arches and arterial branches of fishes, although no respiratory apparatus is connected with them; and in fact the distribution of the vascular system of the bird on the fourth and fifth days exactly resembles that presented by many cartilaginous and bony fishes, as seen in the tadpole of Rana. The development of the first pair of arches is obliterated about the end of the fourth day, but a pair of vessels which is sent from it to the head and neck-organs, and which afterwards remains as the third arch. This pair of arches is given off by the arch which previously existed, and proceeds in the same manner as the fourth from the ascending to the descending sorts. On the fourth day the second arch also becomes less, and on the fifth day is wholly obliterated, whilst the third and fourth become stronger. From the third arch, now the most anterior of those remaining, the arteries are given off which supply the upper extremities; and the veins of the head are now brought into connexion with it by means of the communicating branches, which previously joined the third with the second arch. When these vessels are fully developed, the branches by which these arches formerly sent their blood to the head and neck, disappear, so that about the thirteenth or fourteenth day the whole of the blood sent through the two anterior arches is carried to the head and upper extremities, instead of being transmitted to the descending sorts as before. There now only remain the two vessels, which are now called the fifth pair of branchies, and the development of which into the sorts and pulmonary arteries will be described in connection with the changes which are at the same time going on in the heart. During the fourth day the cavities of the heart begin to be divided for the separation of the right and left auricle. At the 80th hour the commencement of the division of the auricle is indicated externally by the appearance of a dark line on the upper part of its wall, and this after a few hours is perceived to extend as a continuous line from the left ventricular cavity, divides it into two nearly spherical sacs. Of these the right is at first much the larger, and receives the great...
systemic veins; the left has then the aspect of a mere appendage to the right, but it subsequently receives the veins from the hypogastric organs and acquires an increased size. The septum between the arieties is by no means completed at once; a large aperture (which subsequently becomes the foramen ovale) exists for some time at its lower part, so that the ventricle continues to communicate with the arieties as a whole; this is often closed by the prolongation of a valvular fold, which meets it in the opposite direction; it remains pervious, however until the animal begins to respire by the lungs, and sometimes is not completely obliterated even then. The division of the venous system is also hastened by the absorption of the septum, and is effected by a sort of duplicature of its wall, forming a fissure on its exterior and a projection on its interior; and thus a septum is gradually developed within the cavity, which finally incloses the right atrium and rises higher up, until it reaches the entrance to the bulb of the aorta, where some communication exists for a day or two longer. At last however the division is complete, and the inter-ventricular septum becomes continuous with the inter-auricular, so that the heart may be regarded as completely divided in two. The progressive stages presented in the development of this septum are evidently analogous to its permanent conditions in the various species of reptiles; but it must not be lost sight of that in all reptiles the inter-auricular septum is first determined, and the separation of the arieties into two branches, in which the inter-ventricular septum is absent or imperfect. The changes which occur in the heart of the Mammalia are of a precisely similar character, and as they take place more slowly than in the bat, are more clearly connected with environmental influences. After the septum of the ventricles begins to be formed in the interior a corresponding notch appears on the exterior, which as it gradually deepens renders the apex of the heart double. This notch between the right and left ventricles continues to become deeper until about the eighth week in the human embryo, when the two ventricles are quite separated from each other except at their bases; this fact is very interesting from its relation with the similar permanent form of the Dogong. At this period the internal septum is still imperfect, and particular cavities communicate with each other, as in the chick on the fourth day. After the eighth week however the septum is complete, so that the cavities are entirely insulated; whilst at the same time their external walls become more connected towards their bases, and the notch between them is diminished; and at the end of the third month the ventricles are very little separated from one another, though the place where the notch previously existed is still strongly marked.

A knowledge of the changes which go on in the development of the heart enables us to explain some of the malformations to which it is subject. (Carpenter, Principles of Physiology, General and Comparative.)

HEATHER. [Enica.]

HEIMA, a genus of Plants belonging to the natural order

Lythraceae. It has a hemispherical campanulate calyx, bracteolate at the base, with six erect lobes and as many alternate branches, with three alternate with erect lobes; stamens 12, somewhat equal; ovary sessile, nearly globose, 4-celled; capsule included within the calyx; seeds numerous, minute, and wingless. Glabrous herbaceous plant.

Petunias l-flowered, shorter than the calyx.

H. salicifolia. New Zealand. — A plant of the volcano of Jorullo. It has ternate or opposite leaves, the upper often alternate, on very short stalks, lanceolate, acute, narrowed to the base. The petals are obovate. It is a powerful auditive and diuretic. The Mexicans consider it a valuable medicine, and call it Hanchillo.

HEINE, HEINRICH, was born on the 1st of January, 1800, at Düsseldorf, in the Prussian Rhine-Province, of a learned Jewish family. He was educated at the Lyceum at Düsseldorf, and as he was intended for the mercantile profession, he was sent in 1818 to Hamburg, to receive the necessary instruction and training. He remained there till 1819, when his father, as well as his uncle, Solomon Heine, a banker in Hamburg, expressed the wish to be educated for a literary profession, and in the summer of that year he was sent to the university of Bonn, in order to study jurisprudence. In 1830 he went to Göttingen, but soon left it, and in 1831 removed to Berlin, where, in 1832, he became an adjutant to the Magistrate of the 'Gedichte, von Heinrich Heine,' 12mo. Some of the earliest of these productions date as far back as 1816, and several of them had previously appeared in the periodical called 'Der Vater der Vaterlande,' or 'Vater und Vaterland,' which he published, and after his return to Berlin published his remarks in the 'Gesellschaft.' In 1833 he published his tragedy of 'Alceste,' together with a one-act tragedy named 'William Radecliff,' and a 'Lyrisches Intermezzo.' While he remained at Berlin he also published in the 'Spracher' a series of letters under the head of 'Briefe ans Berlin,' which attracted much attention. In 1833 he returned to Göttingen, and resumed his studies in jurisprudence. On the 30th of July, 1835, he took a degree in law, and then proceeded to Hanover, where he began to make himself known as an advocate. The practice of the law however seems to have been as little suited to the character of his mind, now developing itself, as the pursuits of trade. He appears about this time in a letter addressed to his father, who remonstrated against the change of his profession, to have been taken with the idea that the change from the New to the Old Testament, in the Lutheran form, but afterwards became an unbeliever. While at Göttingen, in 1834, he made a tour in the Harz Mountains, of which he published an account at Hamburg, 'Die Harrenise.' 1835. His afterwards made tours in the islands of the North Sea, in England, to South Germany, and to Italy, and wrote a descriptive account of each. The whole of these, including the 'Harrenise' were published at Hamburg under the title of 'Reisebilder, vol. 1-2 in 1835-37, and vol. 3 in 1835-39. The former contains letters written in French under the title of 'Impressions de Voyages.' 1837 He published at Hamburg another volume of short poems, the 'Buch der Lieder,' and about the same period his poem of 'Alta Trol, ein Sonnemachtszegern.' After his return from England he was employed at Stuttgart as the editor of the 'Neue Politischen Annalen.' He also wrote for the 'Morgenblatt,' and the 'Augsburger Zeitung,' and of the latter he became afterwards the Paris correspondent.

In 1837 he removed to Paris, where he was enabled to reside during the remainder of his life. In this year he published his series of letters 'On Nobility' ('Über den Adel'), Hamburg, 1831. In 1838 he published an essay on modern literature in Germany, 'Zur Geschichte der Kunste in Deutschland,' in 1838. His travels in France and in England, and his remarks on the state of France, 'Französische Zeitungen,' 12mo, Hamburg, which is a collection of articles previously published in the 'Augsburg Gazette,' 'Der Salze,' one of the most important of his prose works, was published at Hamburg, in 4 vols. 8vo, 1834-40. About this period he married a Frenchwoman, who was a Roman Catholic, and married her according to the Roman Catholic ritual. His observations on the 'Romantic School' ('Die Romantische Schule') appeared in 1836 at Hamburg. In 1840 he published his bitter personal attack on Börne, with whom he had become acquainted when he went to Paris in 1831, 'Über Ludwig Börne,' 8vo, Hamburg. In the winter of 1843-44, Heine visited Germany for the last time. He then returned to Paris he published his 'Deutschland, ein Wintermärchen' ('Winter's Tale'), which is a description of his journey. In 1847 he experienced an attack of paralysis, which deprived him of the sight of one eye. In 1848 he went to Lausanne; in 1845 he returned to Paris. In 1848 deprived him of the sight of the other eye also, and subjected him likewise to extreme bodily suffering, without all injuring his mental faculties. He never afterwards left his chamber, but continued his literary labours by the light of a small lamp. He died at his villa of Montenot, near Paris, only interrupted occasionally by the severity of his sufferings. His latest poetical productions were the 'Romancer,' written in 1850-51; 'Das Buch des Lazarus,' written in 1854, and 'Nener Frühlings' ('New Spring'), written in 1855. In July 1856 he published at Paris, in the 'Biblio-
HEI 301 HER

these Contemplations," a translation of his poems into French prose, under the title of 'Poèmes et Legendes, by Harri Heine.' The translations were made under his own supervision by his friend, the late Gérard de Nerval. A similar translation of the 'Nouvelles' of Flaubert appeared in this 'Rêves des Mondes,' vol. xi. 1885. His state of body suffering, during which he was dutifully attended by Madame Heine, was terminated by her death, on the 17th of February, 1886. Since Harri Heine's death, his brother, Dr. Gustav Heine of Vienna, communicated to the 'Freundebliet' of that city some particulars of his last moments, together with the seventh clause of his will, in which he says, 'Though I believe that I do not deserve to be followed to the grave by any clergyman of that denomination, and I wish to dispense with any other sacred solemnity at my burial. This is not the weak fancy of a freethinker. For the last four years I have cast aside all philosophical pride, and have again felt the power of religious truth.' He regrets having so often spoken of sacred subjects in a disrespectful manner, and implores 'forgiveness for any offence which in his ignorance he may have given to good manners and morals, which are the true emanations of all faith.'

HEIRATH. (Heir.)

HERB. [Parma.] HERBARIUM, the name given to specimens of Plants when they have been collected and dried. The possession of an herbarium is almost essential to the study of systematics. By it the student of Botany is enabled to cultivate at once the larger proportion of the species of plants which inhabit the earth's surface. The use also of an herbarium will be found constantly to supply the place of recent plants. Hence all persons who study botany possess themselves of an herbarium made up at the expense of nature of their studies. The following hints for forming an herbarium are chiefly derived from Professor Balfour's valuable 'Class-Book of Botany':—

The specimens to be kept in the herbarium should, if possible, be gathered in fine weather, and free from external moisture. In selecting them care should be taken to have the plants in a perfect state of growth, with all the parts from which the characters of the order, genus, or species, are taken. The entire plant, where practicable, should be preserved. Of course this is impossible with trees, but the complete the specimen the better for study. In trees, portions of the branches, with the leaves, flowers, and fruit, should be taken, and, where possible, sections or small portions of bark, roots, &c. In the case of tall and slender grasses and sedges, they may be folded once or twice backwards and forwards, to make room for them on a single sheet. Thick branches, roots, stems, &c., may be cut into lengths of 3 or 4 inches, and inserted in the sections, with the courtesy of the researchers, both the staminiferous and pistilliferous flowers should be obtained. Some plants, as species of the genus Rubus and Salix, demand that both flowering and leafing shoots should be gathered. In gluing the plants on to the paper, care must be taken to expose two or three sides, so that all parts of the habit and structure may be seen. Careful dissections of plants may be dried and fastened on to paper, and these will facilitate subsequent examination very much. All bad, doubtful, injured, or imperfect specimens should be rejected.

In collecting plants a few rules are useful, and when gathered they should be placed in a tin box or vacuum till they are transferred to paper. Some plants require drying or pressure immediately. Under these circumstances, Dr. Balfour recommends both a flat and a sheet, so that all parts of the habit and structure may be seen. Careful dissections of plants may be dried and fastened on to paper, and these will facilitate subsequent examination very much. All bad, doubtful, injured, or imperfect specimens should be rejected.

In collecting plants a few rules are useful, and when gathered they should be placed in a tin box or vacuum till they are transferred to paper. Some plants require drying or pressure immediately. Under these circumstances, Dr. Balfour recommends both a flat and a sheet, so that all parts of the habit and structure may be seen. Careful dissections of plants may be dried and fastened on to paper, and these will facilitate subsequent examination very much. All bad, doubtful, injured, or imperfect specimens should be rejected.

In putting down the plants the following plan should be pursued:—A parcel of not less than four sheets of paper is put on one of the outside boards, then one or more specimens are laid on this sheet according to their size. The specimens should be spread out carefully, their natural habit being preserved as far as possible. When plants require to be folded, the slips of paper already mentioned are passed over the bent portions so as to keep them in place. After placing one specimen or set of specimens on the sheet, another parcel of not less than four sheets is laid over them; and in doing this the leaves and other parts are arranged with the hand or the forceps. The slips of paper are then folded, and if necessary more such parcels have been arranged one over the other. Then a thin board is inserted, and other parcels of paper and specimens are arranged above it, until they are exhausted, or until the bundle is of sufficient size. Another such board is then inserted between the bundle and the forceps, as it is impossible to cultivate at once the larger proportion of the species of plants which inhabit the earth's surface. The use also of an herbarium will be found constantly to supply the place of recent plants. Hence all persons who study botany possess themselves of an herbarium made up at the expense of nature of their studies. Careful dissections of plants may be dried and fastened on to paper, and these will facilitate subsequent examination very much. All bad, doubtful, injured, or imperfect specimens should be rejected.
first by immersion in boiling water. Aquatic plants and wet plants should be placed in a napkin and pressed before they are put into the paper. The moist paper will dry in ten or twelve hours. Along with the plant a label should be affixed, giving particulars known about the specimen, as where gathered, what elevation, &c.

When the specimens are thoroughly dry a selection is made for the herbarium. These should be fastened by means of a spot of gum on a wide paper, which comes long and 10½ inches broad. The name of the plant, its locality, or any other particulars, may be then written on the paper. In order to preserve the specimens from the attacks of insects, &c., they should be touched with a strong solution of corrosive sublimate, or sublimate powder, or in a solution of naphtha (half a drachm to the ounces). The sheets may then be arranged in a case, according to their genera or natural orders.

Fruits, specimens of wood and bark, large roots, lichens and algae on rocks and stones, may be arranged in drawers, glazed cases, or glass jars. Succulent fruits and roots are best preserved in a strong solution of salt and water, or in pyrogallic acid, diluted with 3-5 parts of water, or in alcohol. In some instances a solution of 4 ounces of bay salt, 3 ounces of burnt alum, and 5 grains of corrosive sublimate, in 2 quarts of boiling water, has been used with advantage. These jars are best covered with a stout piece of camphor tied round the neck.

HERCULES. A genus of Plants belonging to the natural order Porophyceae. It has 5 sepals; 5 stellate petals inserted with the 5 stamens on a perigynous ring; 2 stigmas nearly sessile; fruit 1-seeded, indehiscent, membranaceous, leathery, brown in colour, and containing several seeds in place. Three have been recorded as natives of Great Britain. One, H. hercula, is a downy native; the other two are very rare.

H. glabra has a prostrate herbaceous stem, with clusters of small white flowers coalescing on the lateral branches into slightly leafy spike. It has been found in Suffolk and Lincolnshire in England, and in West Kerry, Ireland.

H. ciliata. The sepals are tipped with a large bristle; the clusters of flowers are distinct, sessile, and axillary. It has been found at Lizard Point, Cornwall.

HERMINIUM, a genus of Plants belonging to the natural order Orchidaceae and the tribe Ophrydineae. The perianth is bell-shaped, segments all erect; lip 3-lobed, tumid beneath at the base, without a spur; glands of the stalks of the pollen-masses exserted, naked. H. monorchis, the Musk Orchis, is a British species. The stem is about six inches high, and the spike of flowers is dense and slender; the sepals are ovate and greenish.

HERNAY, or HERNAWAY, a name for the Common Heron. (Héron.)

HERON'S BILL. (Erodium, L. H.)

HERSCHEL, CAROLINE LUCREZIA, the sister of the great astronomer Sir William Herschel, was born at Hanover on the 16th of March, 1760. Till her twenty-second year she lived with her parents in her native place; after which she came over to England with her brother, then established as an organist at Bath. When Sir William exchanged his profession as a musician for those of astronomical labour which were to immortalise his name, his sister became his constant and most valuable helper. "First of all," he says, "he procured his astronomic results," a saying which is often repeated by an authority who writes from intimate knowledge, "her attendance on both his daily labours and nightly watches was put in requisition, and was found so useful that, on his removal to Datchet and subsequently to Brough, she performed the whole of the arduous and important duties of his astronomical assistant—not only reading the clocks and noting down all the observations from dictation, as an amanuensis, but subsequently executing the whole of the extensive and laborious numerical calculations necessary to render them available for the purposes of science, as well as a multitude of others relative to the various objects of theoretical and experimental inquiry in which, during his long and active career, he was at no time engaged. For these labours she was in receipt of a moderate salary allowed her by George III. But, in addition to these labours performed expressly as her brother's assistant and amanuensis, she found time to perform others of a similar character on her own account. Though living up frequently all night till day-break, more especially in winter, while her brother required her help, she was able, by snatching such intervals of time as her brother's occasional absences permitted, to conduct a series of observations on her own with a small Newtonian telescope, which he had constructed for her. Her special employment with this instrument was to sweep the heavens for comets; and so successful was she in this employment that she discovered seven comets, of at least five of which she was situated to have been the first to observe. The dates of the discoveries of the seven comets were as follows:—August 1, 1786; December 21, 1786; January 9, 1790; December 16, 1791; October 7, 1793; November 7, 1793; August 6, 1797. Besides the discovery of these comets, she had the merit of having discovered a new species of nebulae and clusters of stars, included in her brother's catalogue.

In 1796 she published, with an introduction by her brother, an astronomical work of great value, entitled 'Catalogue of Stars,' taken from Mr. Flamsteed's tables, contained in the second volume of the Historia Coelestis, and not inserted in the British Catalogue, with an Index to point out every observation in that volume belonging to the stars of the British Catalogue: to which is added a collection of Errata that should be noticed in the same volume. In this work, which was published at the expense of the Royal Society, no fewer than 661 stars observed by Flamsteed, but which had escaped the notice of the framers of the 'British Catalogue,' were pointed out. During the whole of her brother's residence at Hanover, she was employed by his side, aiding him and modestly sharing the reflection of his fame. After his death, in 1822, she returned to her native Hanover to spend the remainder of her days. They were annually visited by her brother's friends, and, more particularly, by several remarkable nebules and clusters of stars, included in her brother's catalogue.

HILL, ROWLAND, VISCOUNT, was born on the 11th of August, 1772, at the village of Frees in Shropshire, where his father, John Hill, Esq., resided till the death of his brother, Sir Richard Hill, Bart., when he succeeded to the title, and removed to the family mansion and estate at Hawkstone in Shropshire. Sir John Hill had sixteen sons and daughters, of whom Rowland Hill was the second son and fourth daughter. In 1783 he entered the celebrated Hill, the celebrated preacher. He was educated in his native county, where he remained till 1790, when he entered the army as an ensign in the 35th regiment of foot. Having obtained leave of absence, he went to a military academy at Strasbourg, where he remained till January 24, 1794, when he was appointed lieutenant in an independent company under Captain Broughton. On the 16th of March, in the same year, he was appointed lieutenant in the 33rd, or Shropshire regiment. He went to pursue his military studies at Strasbourg, but returned to England at the end of the summer, joined his regiment at Edinburgh January 18, 1795, and remained in Scotland till the end of the year. He served in the West Indies, and returned to England in June. Lord Hood having taken Tolvm from the French in August 1795, Captain Hill, better
HIN

1803

he was attached to any particular corps, was employed there as an ordnance officer, and served in various capacities under successive Generals, Lord Malvern, General O'Hara, and Sir David Dundas. On the 13th of December, 1793, Lord Hood and Sir David Dundas appointed him the bearer of despatches to England, where he arrived on the 14th of January, 1794. In the early part of that year, Lord Graham (afterwards Sir Thomas Graham, and subsequently Lord Lynedoch) having raised a regiment of infantry, ordered Captain Hill the rank of major in it, on the condition of his supplying a certain quota of men, which he did. This regiment was the 80th, with which he served until he was despatched to win 2000 men, and he was promoted to the rank of lieutenant-colonel. On the 1st of January, 1800, he was advanced to the rank of colonel.

After the defeat of the French he returned to England, where he arrived on the 1st of April 1802. He performed regiments' duty in England and Ireland till 1805, when he accompanied the expedition to the river Weser in Germany, but was again in England at the end of January 1806, when he was appointed to the rank of major-general, and appointed on the staff.

In 1808, when he was on duty in Ireland, he received an order to join the army of Sir Arthur Wellesley in Portugal. He arrived there in time to serve with the 1st and 6th, and served under Sir Arthur Wellesley till the French evacuated Portugal, according to the terms of the so-called convention of Cintra. He afterwards served with his regiment under Sir John Moore in the latter part of 1808, till the battle of Corunna, January 16, 1809, when he returned with the shattered remains of the army to England.

After a short stay in England, Major-General Hill, in 1809, re-embarked for Portugal, in command of the troops ordered from Ireland for the next expedition, and was promoted to the rank of General. He served under Sir Arthur Wellesley till the 6th of February 1811, when he was compelled by illness to come to England. In May 1811 he was again in Portugal. In March 1812 he was invested by Lord Wellington with the insignia of the Order of the Bath, which he had been sent over for that purpose by the Secretary of State. He received a slight wound on the head at the battle of Talavera, and received the thanks of both houses of parliament for his services in that action, as he did on other occasions after the battle of Varennes. The General commanding in Chief of the Army—an office which he filled with universal approbation till the declining state of his health compelled him to resign his regiment. He was raised to the dignity of Wellesley, 5th, 1815, with remainder, as near as the second Viscount. He died December 10, 1842, at his residence, Hardwicke Grange, near Shrewsbury.

A colonel in honor of Lord Hill, erected by subscription that year, 1829, Lord Hill was appointed the General Commanding in Chief of the Army—an office which he filled with universal approbation till the declining state of his health compelled him to resign his regiment. The structure of plants and animals. The ultimate composition of organised bodies was unknown to ancient observers, as well as those who lived in the middle ages. It is true that Aristotle and Galen speak of homogeneous and heterogeneous parts of the body; and Malpighi, at the beginning of the sixteenth century, found still a little the idea that what are now called the tissues of the body, yet the more minute structure of these parts was entirely hidden from these observers. Even after the time of Malpighi and Leonardo da Vinci, men thought of looking for the same minute structural organization of the tissues till the beginning of the present century. We can only point to such men as Fontana, Musa, Lieberkühn, Huxton, and Prochaska, as having engaged in isolated observations upon the structure of various parts. It was not till the year 1746 that a connected view of the structure of the human body was given to the world, in such a form as to lay the foundations of what is now called the science of Histology. The 'Anatomie Nécessaire' (Paris 1746) of Bichat was in fact the first attempt to treat the subject of Histology scientifically. It was not so much that Bichat contributed new observations on this subject, as that he systematically arranged what had hitherto been done, and called attention to the importance of the subject, and to the fact that it lay at the foundation of all physiological and pathological inquiries.

In the direction of botany, the present century witnessed the observations of Robert Brown, who was the first to draw the attention of botanists to the importance of minute observations upon the tissues of plants. Of the earliest attempts at a systematic arrangement of the tissues of plants was made by Slack, in the 39th volume of the 'Transactions of the Society of Arts,' in a paper on the Elementary Tissues of Plants and in Vegetable Circulation. Observations were made on the way in which the cells multiplied, and a greater value and interest was given to these than they had before possessed by the observations of Schleiden on the origin and development of the cells of plants in his paper on Phytogeny, published in Muller's 'Archiv für Anatomie und Physiologie,' Part ii. 1838. He here pointed out, that in the formation of vegetable cells, small sharply-defined granules are first generated in a granular subsance, and around them the cell-nuclei (cyto- blastic Nuclei) appear which appear like granular coagulations around the granules.

The results of these observations were communicated in 1837 to Schwann, who, struck with the resemblance between the cells of animals and those of plants, conceived the idea that the same history of development would be found true of the parts of animals that had been discovered by Schleiden in the parts of plants. From this time the science of Histology made rapid progress, and we cannot more appropriately give this condition of the science than in the language of Professor Kölliker, in his introduction to his 'Manual of Human Histology':—

"In the year 1836 in fact the demonstration by Dr. Th. Schwann to the effect that the originally perfectly identical cellular composition of all animal and vegetable tissues is constant in all higher structures from these elements, afforded the appropriate conception which united all previous observations, and afforded a clue for further investigations. If Bichat founded Histology more theoretically by constructing a system and carrying it out logically, Schwann has by his investigations afforded a basis of facts, and has thus won the second laurels in this field. What has been done in this science since Schwann has been indeed of great importance to physiology and medicine, and a further fact of great value in a purely scientific point of view, inasmuch as a great deal which Schwann only indicated or shortly adverted to, as the genesis of the cell, the import of the nucleus, the development of the higher tissues, their chemical relations, &c., has received a further development, but all this idea has not amounted to a step so greatly in advance as to constitute a new epoch. If, without pretensions to precidency, it be permitted to speak of the future, this condition of Histology will last another century, when the essential advancement in the penetrating more deeply into organic structure, and becoming acquainted with those elements of which that which we at present hold to be simple is composed. If it be possible that such constituent cell-membranes, muscular fibres, axile fibre of nerves, &c., and the laws of their apposition and of the alterations which they undergo in the course of the origin, the growth and the activity of the present so-called elementary parts, should be made out, then a new era will commence for Histology, and the discoverer of the law of cell-genesis, or of a molecular theory, will be as much or more celebrated than the originator of the doctrine of the composition of all animal tissues out of the cell.

"In characterizing the present position of Histology and of its objects, we must by no means forget that, properly speaking, it considers only one of the three aspects which the elementary parts present to observation, namely, their form. It is the obligation of the last to unite itself with the second, in securing the correct understanding of the microscopic forms, and with the laws of their structure and development, not with any general doctrine of the elementary parts.

"Composition and function are only involved in as far as they are related to the origin of forms and to their variety.

"Whatever else respecting the activity of the perfect elements and their chemical relations is to be found in Histology, is there either on practical grounds, in order to give some useful application of the morphological conditions, or to complete them, as, from its intimate alliance with the subject, it is added only because physiology proper does not afford a due place for the functions of the elementary parts.

"If Histology is to attain the rank of a science, its first new concept of the mind and certain objective basis as possible. To this end the minuter structural characters of animal organisms are to be examined on all sides, and not only in fully-formed structures, but in all the earlier periods from their first development.

"The real value of the elements has been perfectly made out, the next object is to discover the laws according to which they arise, wherein one must not fail to have regard also to their relations of composition and function. In discovering these laws, here as in the experiments of those great physiologists and chemists, we must make our progress, and do not neglect to study the work of the mind, for the facts alone tell us what to do, and in the discovery of the fundamental wants of nature, and in the applications of their natural propositions or formulae provide, and thus the laws are enumerated.

"If we inquire how far Histology has satisfied these requirements, and what are its prospects in the immediate future, I think must be a moderate. Not only do we not possess a single law, but the materials at hand from which such should be deduced are as yet relatively so scanty, that not even any considerable number of general propositions appear well founded. Not the least in the ignorance which the microscopist possesses of the parts of animals in general, we cannot be acquainted with the structure of a single creature throughout, not even of man, although he has been so frequently the object of investigation; and therefore it has hitherto been impossible to proceed as near to its goal. It would however be unjust to overlook and depreciate what we do possess; and it may at any rate be said that we have acquired a rich store of facts, and a few more trustworthy propositions. To indicate only the more new investigations in the last decade we have a somewhat acquaintance with the perfect elementary parts of the higher animals; and that we also understand their development, with the exception of the elastic tissue, and of the elements of the teeth and bones. The mode in which these are united into organs has been less examined; yet on this head also much has been added of late, especially in man, those individual organs, with the exception of the nervous system, the higher organs of sense, and a few glands (the parathyroids, for instance), have been essentially investigated. If the like progress continue to be made, the structure of the human body will in a few years be so clearly made out that, except perhaps in the nervous system, nothing more of importance will remain to be done with our Comparative Histology.

"In a word, the subject at hand is of the most fascinating, as it is the most important, the subject of the observations of the times, and one which is advancing more than any other. With Comparative Histology it is otherwise: hardly commenced, not years but decades will be needed to carry out the necessary investigations. Whoever will do good work in this field must, by many means and in various ways, keep pace with the great progress from the earliest periods of development, obtain a general view of all the divisions of the animal kingdom, and then by the methods above described arrive to develop their laws.

"As regards the general propositions of Histology, the student will find them to be discovered in a monumental work by Schwann; however, much has been attained by the confirmation of the broad outlines of his doctrines. The position, that all the higher animals at one time consist wholly of cells, and de-
velop from these their higher elementary parts, stands firm; though it must not be understood as if cells, or their derivatives, were the sole possible or existing elements of animals. In the same way, Schwann's conception of the genesis of cells, though considerably modified and extended, has been essentially changed, since the cell-molecules still remain as the principal factor of cell-development and of cell-multiplication. Least advance has been made in the laws which regulate the origin of cells and of the higher elements; and on the formation of the placenta, the place during the formation of organs must be regarded as very slight. Yet the right track in clearing up these points has been entered upon; and a logical investigation of the chemical relations of the elements forming the animal structure furnish the most solid foundation of Deleers, Donhou, Ludwig, and others, combined with a more profound microscopic examination of them, such as has already taken place with regard to the muscles and nerves, and further, a histological treatment of embryology, such as has been attempted by Heichert, Vogt, and myself, will assuredly raise the veil, and bring it step by step nearer to the desired though perhaps never-to-be-reached end.

We refer here to some of the more important works and papers that have been published on this subject.

Köllicker, Manual of Human Histology; Sharpey, General Anatomy, in Quain's Elements of Anatomy; Beale, The Microscope and its Application to Clinical Medicine; Todd and Bowman, Physiology and Flora; Garber, Elements of the General Microscopic Anatomy of Man and the Mammalia; Goodrich, Anatomical and Pathological Observations; Hassell, Microscopic Anatomy; Bowman, On the Structure of Voluntary Muscles (Phil. Trans., 1840); Kiemun, On the Structure of the Lungs (Phil. Trans., 1830); Mundell, Manual d'Anatomie Générale; Moehl, On the Vegetable Cell; Owen, Lectures on Comparative Anatomy; Queckett, Lectures on Histology; Schiedel, Principals of Scientific Botany; Schiedel and Schwan, Microscopic Researches (Sydenham Society); Galton, Anatomia y Pathology; Robin, Histoire Naturelle des Vegetaux parasites; Carpenter, Principals of Physiology, General and Comparative, (Quarterly Journal of Microscopical Science.)

HON

HOLMAN, JAMES, known as 'The Blind Traveller,' was born in about the year 1876. He entered the royal navy in December 1876, and was appointed lieutenant in April 1887. At the age of twenty-five an illness which resulted from his professional duties deprived him entirely of his sight. On the 9th of September 1882, he was appointed one of the Naval Knights of the Légion of Honour. By degrees, when he had become accustomed to his condition, in 1819, partly the state of his health and partly a desire for change induced him to set out on a journey to the Continent, of which he published a description. On his return, he was taken in the Years 1819, 1820, 1821, through France, Italy, Savoy, Switzerland, parts of Germany bordering on the Rhine, Holland, and the Netherlands; comprising Incidents that occurred to the Author, who has long suffered under a total Deprivation of Sight; by James Holman, R.N. and K.W., 2 vols. 1822. On the 19th of July 1822, he embarked on a voyage to St. Petersburg, whence he proceeded to Moscow, Novgorod, and finally to Irkutsk, the capital of Eastern Siberia. His intention was to proceed through the steppes of Eastern Siberia, which becomes sufficiently flat to have crossed over, and travelled through Mongolia and China. At Irkutsk however an order was received by the Russian authorities from the Emperor Alexander, prohibiting him from proceeding any farther, and he was compelled to return. He was accompanied by a Russian officer to the frontiers of Germany, and was treated with external politeness combined with much harshness and severity. After his return to England he published 'Travels through Russia, Siberia, Poland, the Baltic States, Hanover, Prussia &c., 1823, 1824,' while suffering from total Blindness, and comprising an Account of the Author being conducted a State Prisoner from the Eastern Parts of Siberia, 2 vols. 1825.

HOLSWORTHY, [Devonshire.]

HONDURAS, Republic of, Central America, occupies the elevated country between the table-land of Guatamala and the plains of Mosquitoes and Nicaragua. It lies between 14° and 15° 30' C. long, and between 80° and 81° 30' W. long. Between Cape Eleonora and Cape Horn, but a narrow tract extends southward between Salvador and Nicaragua as far as the Gulf of Conchagua on the Pacific, 18° 30' N. lat. Honduras is bounded E. by the Mosquito territory, by the Rio Motagua, R., whose boundary line on this side remains undefined; S. by the river of Nicaragua, on a line where the narrow tract of land reaches down to the Gulf of Conchagua; W. by Guatemala; and N. by the Caribbean Sea. The area is about 30,000 square miles; the population is about 250,000, of which about 4,000 is black or mulatto. Surface. — The Caribbean coast from Cape Cameron to Cape Honduras bears, with a general concave sweep, due west, and thence to Caballo Point, and to the mouth of the Rio Motagua, a short distance east of which is the boundary between the republics of Honduras and Nicaragua. The northern coast is low; thence westward it is for the most part high and rocky. The only available ports are Truxillo at the mouth of the river of the same name, which is merely a small stream in the bottom of a large mulatto. Cape Honduras; and Omoa, a small but good harbour near the western extremity of the republic. The whole of this coast is extremely unhealthy, and consequently very thinly populated. The small tract owned by Honduras bordering on the Gulf of Conchagua, in the Pacific Ocean, is also low, subject to be inundated by spring tides, and very unhealthy; but in neither case does the miasmatic influence extend far inland.

The surface of the country is greatly broken. It may be described as a table-land traversed by several ridges of hills running from north-west to south-east with secondary ridges branching obliquely from them. The general level of the table-land is perhaps about 4000 feet; the highest part is probably in the southern coast. The shores of the Caribbean Sea a ridge of mountains, the Sierra Omos, extends from Cape Honduras to Caballo Point, near which is Mount Omoa,7000 feet high, which gives its name to the ridge. The culminating point of this ridge is the peak of Congress, 7th W. long, which is 8000 feet above the level of the sea. The ridges which traverse the interior of Honduras do not attain any great altitude above the general level. Between the ridges are long, wide, open and fertile valleys, which form a well defined and gradually broadening east. Near the western end of the state are the broad valleys of the Chamalico and the Uima, which are overgrown by thick forests of mahogany, cedar, and castic trees. Along the southern side of the territory runs a ridge which divides the waters which flow into the Pacific from those which fall into the Atlantic; but only a few peaks attain any considerable elevation. From this ridge, and from the transverse ridges north-west of it, a series of high and steep hills rise from a broad plain, and connect the table-land of Honduras with that of Guatemala. The valleys between these ridges are of comparatively moderate width.

The principal rivers flow into the Caribbean Sea. Beginning on the west we have the Chamalico, which rises on the Mereyendi, which flows from a broad plain generally northern direction into the Bay of Honduras a little east of Punto de Caballos. For a large part of its upper course it flows through a wild and uninhabited country; but as it approaches the sea the valley opens out to a great

2 R
width, its slopes being covered with vast forests of valuable timber trees. Like most of the rivers of the state the navigation of the Chamacón is impeded by a bar at its mouth. East of the Chamacón is the Ulúa, a much longer and narrower stream. It is formed by the confluence of several branches, the longest of which rises not far from the borders of Salvador; it falls into the sea a short distance west of Punta de Sal after a course of about 300 miles, and forms the mouth of the longest navigable river of the continent. The next river of any size is the Truxillo, the mouth of which forms the harbour of the same name. East of this is the Ajan, which after a course of about 100 miles discharges itself by two branches into the Caribbean Sea, about 30 miles east of the mouth of the Ulúa. None of these are navigable for more than a short distance, and then only by piragua (a sort of river barge), except the Ulúa and Chamacón, which admit small schooners. The Choluteca, which falls into the Pacific at the entrance of Conchagua, a small stream draining a narrow valley, is the only river of the state which does not enter the Caribbean Sea. The roads throughout the republic are mere tracks worn by continual use.

**Climate, Soil, Productions.**—The climate, except along the coast, is on the whole salubrious, though the temperature is somewhat high. Guatire is common in the elevated districts. The valleys opening to the sea are very fertile, but moist and unwholesome. Those from which the air is intercepted by ranges of hills are less humid and more habitable. The rains fall in the hot season, in the north and in the districts not contiguous to the Caribbean Sea, the dry season begins about the close of October, and lasts until the end of May; during which time only a few showers occur. In the month of June thunder is frequent, and is followed by long and heavy rains.

The most important natural productions are the vast forests of mahogany, cedar, busti, pimento, and numerous other valuable trees. They are also productive of all the crops for the benefit of the roads, the scarcity of labour, and other local causes, they are turned to comparatively little account. From the same causes, and from the indisposition of the inhabitants to steady labour in the fields, agriculture is in a very backward state; not only are immense tracts of fertile land wholly neglected, but the land which is under cultivation is very far from being rendered as productive as it easily might be. Maize, rice, some wheat and barley, fríoles, plantains, and various fruits and vegetables are the most important articles, but scarcely in sufficient quantities for the requirements of the inhabitants. In the western districts of Gracias tobacco of very fine quality is raised, but not enough for exportation. The chief minerals are lead, silver, and iron. The latter are found in vast beds on the plains in the interior. Yet though such large numbers are maintained, they form but a limited article of export, and tallow and hides are only exported to a comparatively small amount. Sheep are not so numerous as in some of the other countries of Central America. Horses are not much attended to, nor are they of superior kinds. Mules are numerous, they being generally used in the country for the transport of goods.

The population is confined to the principal articles of home consumption. The commerce is but small; the foreign trade is chiefly carried on through Belize. As already indicated the exports are principally of mahogany, cedar, Brazil, and other cabinet and dyes-woods; sarsaparillas, bibles, and the products of the mines. The imports are British cottons, woolens, and hardwares, with various French, German, and American goods. Honduras is the principal mining country of Central America. The chief metals are lead, silver, and iron. The southern and western portions of the republic, but sometimes coasts, are productive of gold. Gold is found in veins in quartzose rocks; and in grains in alluvial deposits in the ravines, and in the sands of several of the rivers. Silver mines occur in several places in the department of Omo, and in the departments of Yoro, Santa Barbara, and Cortés, and in all the other departments, Copper is found of good quality in Choluteca and elsewhere. Lead and iron-ore are found in several places. Of the present annual products of the mines we have however no reliable statement. In Gracias occur veins of remarkably fine opals, as well as some yielding emeralds. Jasper, amesites, and chinchaca are likewise obtained. Excellent marble is wrought.

**Divisions, Towns, &c.**—Honduras is divided into seven departments: Comayagua, which occupies nearly the entire west coast, and maintains the head of the union; the north-west, and Santa Barbara to the north-west of Comayagua, both of which extend to Guatemala, and Santa Barbara includes the coast as far east as Punta de Sal; Yoro, which contains the district of the same name and extends from the mouth of the river of that name southeast to Cape Honduras, and contains the port-town of Truxillo; Tegucigalpa lies east of Comayagua, and is the chief mining district and most thickly inhabited department of the republic; on the north-east of it is the department of Choluteca, which contains the town of that name and the eastern districts; Comayagua is Choluteca, which stretches down to the Gulf of Conchagua, where is the little port-town of San Lorenzo, established a few years back in order to give the republic a port of entry on the Pacific. In the interior are several considerable towns; on the coast are only the small port-towns of Omo and Truxillo.

Comayagua (Valladolid de), the capital, is situated in a fine but unhealthy valley, at nearly an equal distance from the ports of Omo and Truxillo, in 14° 20' lat., 87° 30' west, and contains 5000 inhabitants. The public buildings are a cathedral, several churches, a college, an hospital, &c.

Topicalgapa contains from 8000 to 10,000 inhabitants, and is the most populous place in Honduras, being the chief town of the northern departments. The port of Tepic, or Truxillo, is a small place inhabited by a few ladinos, but is a good salt-warehouse, the harbour, which is formed by a small bay, is very good. The goods imported from Europe or America, are sent by barges to Guaná, on the banks of the Motagua.

The town is very unhealthy. The roads in the district of Tegucigalpa were constructed by the Spaniards in 1802. The Spaniards effected the subjugation of the country a few years later; from which time it remained a part of the Spanish kingdom of Guatemala until the declaration of independence by South America in 1824. Honduras was then comprised in the Mexican empire of Yucatán, on the dissolution of which in 1823, Honduras formed one of the federal states of Central America; but this union was also of short duration, and Honduras then became and has since continued to be an independent republican state.

(Jarros, History of Guatemala; Headkins, Central America; Baily, Central America, &c.)

**HONDURAS, BRITISH, or BELIZE,** a British settlement on the east coast of Central America, is bounded N. by Yucatan, W. by Vera Paz, S. by Guatemala, and E. by the Bay of Honduras and the Caribbean Sea. The settlement extends from 15° 54' to 15° 30' N. lat., and from 85° to 89° 30' W. long. The area is about 10,370 square miles, and the population, which consists chiefly of Caribs and negroes, is about 5000.

The surface is very irregular. In the interior it is greatly elevated, while the coast is for the most part low, and fringed with reefs and small islands, termed keys, which form the best harbours. The coast is frequently frequented by storms, and is watered by numerous rivers, the chief being the Belize, which is navigable for 150 miles from its mouth. The rocks are principally primary and calcareous. The easterly or seafires which prevail during nine months of the year, temper the heat, which however is scarcely ever excessive; the
The thermometer seldom rises above 80° Fahr. even in the hottest time, and during the wet season it sinks to 60°. In June, July, August, and September heavy and frequent rains fall, and these are the most unhealthy months of the year, disease being engendered by the marish使命感 arising from the levees and swamps. The soil by the coasts and rivers is a rich alluvial deposit, and very fertile. On the higher grounds are marly soils, sandy marly-soils, or magnesite-
nesses, and the logged-wood arboretum in the hills. Cedar and other valuable timber-woods are among the natural products. The plantain is extensively cultivated. Maize, rice, cassava, arrow-root, yams, &c. are grown. Cotton, maize, rice, cassava, &c. are grown. Of the birds that are nearly extinct, the woodcock, the black tiger, the black-cat, the leopards, and other wild animals, and game, are found. Turkeys abound on the shores.

British Honduras is governed by a Superintendent, and a Perpetual Court, consisting of seven magistrates appointed by its inhabitants. The superintendent is immediately subordinate to the Governor of Jamaica, from whom he holds his commission. He is assisted in the administration of government by an Executive Council consisting of the chief justices, the attorney-general, the officer commanding the land forces, and the public treasurer. An Act of the local legislature has however been passed by which the constitution of the council and assembly is proposed to be altogether remodelled. The raising of the capital, and indeed only town of any size, Belize, or Belmopan, under which it is more fully noticed, and where will also be found mentioned various other facts relating to the settlement. [Belize, or Belmopan.]

HOMESTONE. [MELIATA.]

HONEY-SUCKLE, FRENCH. [HEDYARUM.]

HONKENNEJA, a genus of Plants belonging to the natural order Coryophyllales, and the sub-order Alstroemeriaceae. It has 6 species, all large perennials, with ample, sessile, or very few, large seeds.

H. pedicellata in a British species found on sandy sea-coasts. It has ovate-acute sessile leaves,舟形, glabrous, and large flowers which are ovate, shorter than the petals, the style is closer, crenulate, or foliaceous; the flowers from the spines of the stem frequently deciduous; capsules large, globose; seeds few, large. [H. pedicellata.]

HOPPER, THOMAS, architect, was born at Rochester, in Kent, July 6th, 1776 or 1777, and, according to a family tradition, was descended from a natural daughter of Richard III. Thomas Hopper, when very young, was placed under his father, a stonemason and Surveyor, and it is supposed he very soon had the chief duty and responsibility of the business. Thus led to direct his attention to architecture, he became in some degree a self-taught architect; and when this time introduced to Mr. Waltham Porter, a friend of the Prince Regent, and of a sort of authority in matters of taste, Hopper was so fortunate as to please Porter, and was employed by him in extensive alterations and restorations to his house at Fulham, called Craven Cottage. His house became a remarkable specimen of the 'cottag

taste, and the art of the day—the character of which last has been sufficiently pointed out above—were suited to one another; and, favourably introduced, and possessing great energy, a work of conformation, and high spirit, it is not surprising that, at a time when there were fewer profess

ional architects than there are now, Thomas Hopper would have speedily entered upon a large practice. Amongst the buildings of all kinds which he was employed either executing or superintending, in Ireland, for the Marquis of Cowguy; Penkyn Castle, near Bangor, North Wales; Glastonbury, Arungh; Easton Lodge, Darrow, for Viscount Maynard; Leigh Park, near Spa, for Sir Thomas Leigh; St. John's House at Kimmeldale, for the Hon. Mr. Wylde; Ashpje, for Lord Dinoriv; the pleasure house at Salisbury; Danbury Palace, Essex; Gatton House, Surrey; Wyvyanooe House; Llanover Court, Monmouthshire, for Sir Benjamin Hall; Stansted Park, near Havant, Plants; Mar

..now you mentioned several different styles—the baronial castellated, then in favour, of being course amongst the numerous. Penkyn Castle is perhaps the best exemplification of the latter kind of taste, and is indeed in many respects impressive in effect, and may be safely said to have been almost entirely expended on it. He designed a baronial castle for the Duke of Atholl, at Dunkeld, in Scotland, which if completed would have rivaled Windsor Castle in extent, though the building never got beyond the foundations. He erected a similar structure for another baron, which afterwards he made alterations costing 40,000L. on its conversion for the cellular system. In London he was the architect of Arthur's Club House, in St. James's-street, the Legal and General Assurance Office in Fleet Street, and the Atlas Fire Office in Cheapside. His general manner for such buildings was derived from the class of edifices to which the Banqueting House, Whitehall, belonged. His last work, St. Mary's Hospital, Paddington, which is inferior in character, and splendidly but not expensively executed, was intended by him greatly and miasma

Honey-stone. [MELIATA.]

Honeysuckle, French. [HEDYARUM.]

Honkenneja, a genus of Plants belonging to the natural order Coryophyllales, and the sub-order Alstroemeriaceae. It has 6 species, large perennials, with ample, sessile, or very few, large seeds. H. pedicellata in a British species found on sandy sea-coasts. It has ovate-acute sessile leaves, boughy, glabrous, and large flowers which are ovate, shorter than the petals; the style is closer, crenulate, or foliaceous; the flowers proceed from the spines of the stem frequently deciduous; capsules large, globose; seeds few, large. [H. pedicellata.]

Hopper, Thomas, architect, was born at Rochester, in Kent, July 6th, 1776 or 1777, and, according to a family tradition, was descended from a natural daughter of Richard III. Thomas Hopper, when very young, was placed under his father, a stonemason and Surveyor, and it is supposed he very soon had the chief duty and responsibility of the business. Thus led to direct his attention to architecture, he became in some degree a self-taught architect; and when this time introduced to Mr. Waltham Porter, a friend of the Prince Regent, and of a sort of authority in matters of taste, Hopper was so fortunate as to please Porter, and was employed by him in extensive alterations and restorations to his house at Fulham, called Craven Cottage. His house became a remarkable specimen of the 'cottag
which may help to justify the position which we have given to his name.

HORHOUND. [Bellota ; Marrubium.]

HORNBLINDE, a Mineral belonging to the group of the Anhydrous Silicates of Magnesia. An account of its general characters and formation is given under Acorsa. It consists in general of crystals differing much in appearance, arising from isomorphism and crystallization. Alumina enters into the composition of some of them, and replaces part of the other ingredients.

The light coloured varieties belong to Tremolite or Grossulite. It comprises the white, greyish, and light-greenish slender crystallisations, usually in blades or long crystals, penetrating the gauze, or aggregated into coarse columnar forms; it is sometimes nearly translucent. The specific gravity is 2-93.

The light-green varieties are called Actinolite. Glassy Actinolite includes the bright glassy crystals of a rich green colour, usually long and slender, and penetrating the gauze like tremolite. Radiated Actinolite includes olivine-green masses, consisting of aggregations of coarse acicular fibres, radiating or diverging. Aedolostrom Actinolite resembles the radiated, but the fibres are more delicate. Massive Actinolite consists of masses of nodules and fibres. The specific gravity is 2-92 to 3-00. [Actinolite.]

Abestus is also included under this division. [Abestus.]

To the dark-coloured varieties belongs Pargasite, a term which is applied to dark-green crystals, short and stout, of a dark red loire, of which Parga in Finland is a notable locality.

The term Hornblende is applied to the black and greenish-black crystals and massive specimens. It contains a large per centage of oxide of iron, and to this it owes its dark coloration. It is a tough mineral. Pargasite and Hornblende both contain aluminous silicate.

The varieties of Hornblende fuse easily with some sulphur, the pale varieties forming a colourless glass, and the dark become more or less covered with iron. Hornblende is an essential constituent of certain rocks, as syenite, trap, and hornblende-slate.

Actinolite is usually found in magnesian rocks, as talc, asbestos, or serpentine. Tremolite occurs in granular lime-stones and dolomite; Actinos is occurs in the above rocks, and also in serpentine. [Data. Manual of Mineralogy.]

HORNBY. [Lancashire.]

HORNSEA. [Yorkshire.]

HORNBY. [Middlesex.]

HORSTONE. [Quartz.]

HOUGHTON-LE-SPRING. [Dorset.]

HOUNSWAY. [Middlesex.]

Plants belonging to the natural order Rhamnaceae. The peduncles of H. dulcis become extremely elongated and succulent, and are in China in much esteem as a fruit, resembling in flavour, it is said, a ripe pear.

Some parts are eaten raw.

HOWARD, HENRY, R.A., Professor of Painting in the Royal Academy, was born on the 31st of January 1769. He was a pupil of Philip Reinagle, R.A., and was admitted a student at the Royal Academy in March 1778. As a student his success was very decided; and it was his fortune, for the first time in the history of the institution, to receive on the same occasion, December 10th, 1790, two of the highest premiums—the first silver medal for the best drawing from the life, and the gold medal for the best historical painting; and he was at the same time appointed the silver medalist, or a silver medal of the president, Sir Joshua Reynolds, for the excellence of his historical design. In the following year he visited Italy, and at Rome he and Flaxman pursued their studies in conjunction.

On his return to England Mr. Howard was employed to make drawings for the Dilettanti Society, and designs for book-plates; he also painted some portraits. His first contributions to the Royal Academy, “These and Anchises” and the “Death of Euryalus” (1796), were much admired by persons of classic tastes; and from this time for more than half a century Mr. Howard continued, without a single intermission, to send to each annual exhibition some paintings almost invariably of the classes of which these works are examples. In fact the whole of his productions in that of a series of pictures which he executed, though illustrating themes from the Scriptures, and from Greek, Roman, Italian, and English history, poetry and mythology, have all or nearly all the same character, for which perhaps there is no word so descriptive as that of ‘academic.’ His figures are almost always well drawn; of elegant proportions; have the established ‘classical’ contour and expression, or absence of expression; are clothed, or partly clothed, in the same costume in which they appeared in ancient pictures, except when their position, wear so easily and gracefully in pictures and statues, despite the ordinary laws of gravity, which however may fairly be regarded as not applying to such beings; and they are almost always presented in an agreeable conformity to the rules of pictorial composition; while the colouring, if not rich and glowing, is chaste and harmonious. They were in fact good ‘academic’ pictures, and they are no more. Always strictly attentive to the correct proportions of the human form, and never rising in action, they often simulate, in a Venus rising from the Sea, ‘a Love animating the Statue of Pygmalion,’ or a cold ‘Primeval Hope,’ that can by any chance give the slightest shock to the nerves of the most susceptible—who is not shocked by the very mere mention of the word ‘undraped female beauty.’ But if his ‘beauties of fair forms’ are never like those of Eutyl trembling on the verge of the voluptuous, they never like them are buoyant with the exuberance of life and youthful vigour—never exhibit the tricks of the eye and the airiness of movement that move action. They are works to be looked at with a certain quiet admiration of the artist’s skill, not to seize the attention and linger in the memory. In a word, they are works of taste, not of genius.

Mr. Howard was elected an associate of the Royal Academy in 1801; in 1808 he became an academican; and in 1811 he was appointed secretary to the Academy, an office he held till his death, though for some years previously its active duties were performed by an assistant. He died on the 4th of October 1828, in the 80th year of his age.

The titles of a few of his pictures will sufficiently indicate the range and character of his subjects. Of his scriptural paintings, the most ambitious are “Christ blessing Little Children,” painted as an altarpiece in the chapel in Little Berwick Street; ‘the Angel appearing to St. Peter in Prison;’ and ‘Aaron staying the Plague.’ The great bulk of his pictures as already mentioned are however those in which the subjects were chosen with a view to afford the opportunity of painting the nude female form; and to this class his best pictures belong. The most admired of these is his ‘Birth of Venus,’ painted in 1829. Others are ‘The Marriage of Cupid and Psyche,’ ‘Prosperine,’ and like stock subjects; but a large number consists of figures floating in the air, as in the ‘Sleeping instants’ as the ‘Fidalgos,’ the ‘Solar System,’ the ‘Circling Hours,’ ‘Morning,’ ‘Night,’ &c. Besides numerous pictures from Spenser, his favourite poet, Milton, Shakespear (especially the ‘Midsommer Night’s Dream’), &c., he also painted the preparatory cartoons for the grand and fanciful subjects with which his name is connected; he also painted many portraits. It deserves to be mentioned as illustrative of his life-long devotion to his art, that not only did he continue to paint pictures for the Academy exhibitions up to the year of his death, but that on the occasion of the first cartoon competition, 1813, he did not shrink from entering the lists, though then seventy-three years of age, and in the rude encounter with the young artists fresh from the schools, his cartoon, ‘Man beset by Contending Passions,’ carried off one of the premiums of 100l. in 1814 Mr. Howard won the prize for a medal for the Patriotic Society, and thefortunately he was generally employed in preparing the designs for the medals and great medals for the Society, he was appointed as an artist to the Seamen’s Fund, and his designs for works to be executed in silver, chiefly for the homes of Rundle and Bridge. Frank Howard, the son of Mr. Howard, is well known as an able designer, and the author of several elementary works on art. To a brief memoir of his father contributed by him to the ‘Academy’ for November 13, 1847, we are indebted for most of the facts in this notice.

HOWLET. [Bramham.]

Hosia, a plant of the genus Hesperis belonging to the natural order Aoeapocadam. It has 6-leaf, rotative corolla. Crown of appendages depressed, 6-leaved; leaflets spreading, feathery, with the inner angle extended into a tooth lying upon the anther. Anthers terminated by a membrane. Pollen-masses are included in the anther. Stigma not parted, or scarcely so. Follicles smooth.

H. viridiflora is a native of Coromandel, Sylhet, and the
Hume, Joseph, was born at Montrose in the year 1777. His father was the master of a small coasting-vessel, and after his death his widow supported herself by keeping a shop in Montrose. Having received the merest rudiments of education, including Latin and a smattering of Greek, at school in his native town, he was apprenticed in his fourteenth year to a surgeon. In 1793 he entered the University of Edinburgh for the purpose of prosecuting his medical studies; and having taken a medical degree, and passed the London College of Surgeons, he was for some years in the employ of his father.

He distinguished himself not only in his medical capacity, but also by acting as pursuer on his voyages out, and conducting a most complicated business in a very successful manner. He was chosen as a fellow of the Royal Society of Edinburgh, in which capacity, which he declines, he is often called upon in colonial and municipal abuses, election expenses, the licensing systems, the duties on paper and printing, and on articles of household consumption. He took an active part in carrying Roman Catholic emancipation bills through the legislative chambers, and in the passing of the Reform Act of 1832. A remarkable passage in his life was his discovery, in 1835, of an extensive Orange plot, commencing before the accession of William IV. An account of this transaction, in all the minuteness of detail, will be found in Miss Harriet Martineau's 'History of the Thirty Years' Peace.'

The health of Mr. Hume began to break soon after the parliamentary session of 1834, and he died at Burnley Hall, his seat in Norfolk, on the 20th of February 1835. At the time of his death he was a representative of the county of Norfolk, in the house of commons, and a deputy lieutenant for the latter county. As a proof of the general esteem in which he was held, we may add, that in the House of Commons there is a picture of him by Mr. Philipon, engraved by Mr. Maguire, as his character. He married a daughter of the late Mr. Burnley, by whom he left a family of several sons and daughters. His eldest son is Mr. Joseph Burnley Hume, barrister-at-law.

Hymotopic Acid. [Chemistry, No. 1.]

Husband. [Divorce, No. 3; Separation, Journals, No. 2; Women, No. 2.]

Hyacinth. [Garden, No. 2.]

Hydrazine, a genus of Plants belonging to the natural order Cereales. H. globosa yields a fruit which is collected by the Cape Coloureds, and is sometimes used as a poison for hares by being rubbed over meat.

Hydra (Linnaeus), a genus of Polypiferous Animals, including the Fresh-Water Hydra, or Polyple. It has the following technical definition:—Polyple locomotive, single, naked, gelatinous, subcylindrical, but very contractile and mutable in form; the mouth encircled with a single series of granulous filiform tentacles.

As of all the forms of polypiferous animals the Hydra is the most interesting, and gives an abstract of their history, from Dr. Johnstone's 'British Zoophytes':—

Leeuwenhoek discovered the Hydra in 1703, and the uncommon way its young are produced; and an anonymous Englishman, Mr. Bouche, in 1760, described the true nature of the life of the Hydra in England about the same time, but it excited no particular notice until Trembley made known its wonderful properties about the year 1744. These were so contrary to established experience, and so foreign to every preconceived notion of animal life, that by many they were regarded as impossible fancies. Leading men of our learned societies were daily experimenting on the creature and transporting it by careful posts from one to another, while even ambasadors were forwarding to their respective courts early intelligence of the amazing accounts. The Hydra are found in fresh waters only. They prefer slowly-running or almost still water, and adhere to the leaves and stalks of submerged plants. The body is exceedingly contractile, and hence liable to many changes of form; when contracted into a sphere, a minute top most is seen; and when extended it becomes a long column, being ten or twelve times longer at one period than another, the tentacula changing in size and form with the body. On the point opposite the base, and in the centre of the tentacula, we observe a canal, or mouth, which leads into a wider cavity, excavated as it were in the middle of its body, and from which a narrow canal is continued down to the sucker. When contracted, and also when fully extended, the surface appears smooth and even; but in the intermediate stages it is alternately wrinkled and crenulated, an effect probably of a wrinkling of the skin. The tentacula encircle the mouth and radiate in a star-like fashion; but they seem to originate a little under the lip, for the body of the mouth is completely surrounded by them. They are cylindrical, linear, or very slightly tapered, hollow, and roughened, at short and regular intervals, with whorls of
tubercles, which under the microscope form a very beautiful and interesting object. The tentacles form a slender membranous tube, filled with an albuminous nearly fluid substance, intermixed with some oozing particles; and at certain definite places this substance swells out into tubercles or denser wartlike nodules, which are arranged in a spiral line. Every nodule is covered with a corolla of filaments, with a small cavity at the base, and with a very singularly constructed organ for catching the prey. The organ of touch consists of a fine sac, inclosing another with thicker parietes, and within this there is a small ball. From the point where the two sacs coalesce above there projects a long cilium, or capillary spine, which is non-retractable and apparently immovable. Surrounded by these cilia, and in the centre of the nodule, is placed the caput organ, called the ‘basta’; this consists of a long and slender sac, immersed in the nodule, and opening out at a small aperture even with the surface. At the bottom of the sac, and within it there is a sac-like vesicle, on whose upper depressed surface is seated a solid ovate corpuscle, which gives origin to and terminates in a calcareous sharp sagitta, or arrow, that can be pushed out at pleasure, or withdrawn, till its point is brought within the sac. When the Hydra wishes to seize an animal, the sagittae are protruded, by which means the surface of the tentaculum is roughened, and the prey more readily held. The cilia become quite at the same time injected—a conjecture offered to explain the remarkable fact of the almost instant death of the prey. The tentacles of the tentaculum are connected together by means of fine transverse fibres, named cords, which, when arranged, the body of the Hydra becomes a viscid, formless, and somewhat papery mass of organ in the form of a portion of a sphere. The cephalic extremity is a viscid, and forms the mouth, the circular aperture of which is lined with a viscid, and forms the mouth, the circular aperture of which is lined with a viscid, becoming in all respects as in size similar to the parent. It remains attached for some time, and grows and feeds, and contracts and expands after the fashion of its parent, until it is at length thrown off by a process of exfoliation or sloughing. They develop with great rapidity in warm weather, and sometimes the young ones themselves breed others, and they again a third or fourth generation before they become separated from the original parent. This generation is much faster, and the young ones, when the parent is a forty-five year-young ones in two months. In autumn the Hydra generates by internal osmotic gymnastics, which extrude from the body, and lie during the winter in a quiescent state, and are stimulated to evolution only by the return of the warm weather. They increase in numbers in these ova, so that their structure, source, manner of escape, and condition, are scarcely known.

These are the modes in which the Hydra naturally multiplies its kind, but it can be increased by artificial means of the body in the same manner that a perennial plant can by shoots or slips. If the body be halved in any direction each half in a short time grows to a perfect Hydra; if it is cut into four or eight or even miniced into forty pieces, each piece, if well treated, will develop into a complete Hydra; it is itself capable of being multiplied in the same extraordinary manner. If the section is made lengthwise so as to divide the body into two or more slips connected merely by the tail, they are quickly reunited into a perfect whole, or if the pieces are kept under each will become a perfect poly. If the tentacles are cut away, new ones are quickly produced, and the lost-off parts are not long without a new body. When a piece is cut out of the body the wound quickly heals, and in a day or two there is the polyp sprout from the wound more abundantly; when a polyp is introduced by the tail into another body, the two unite and form one individual, and when a head is lost off, it may safely be replaced on the body of any other individual, one. And this polyp is capable of bringing itself by all these apparently cruel operations; for before the lapse of many minutes the upper half of a cross section will expand its tentacles and catch prey as usual, and the two portions of a longitudinal division will after a time take food and retain it. A polyp cut transversely is three parts requires four or five days in summer and longer in cold weather for the middle pieces to produce a head and a tail, and the tail part to get a body and head, which they do in pretty much the same time. And what is still more extraordinary, polyps produced in this manner grew much larger and are far more prolific in the way of their natural increase than those which were never cut. When such things had been announced, when a little worm was the first animal body are found to be capable of artificial generation, and the whole of affections of antiquity realied, it is not wonderful that the vulgar disbelieved when naturallists, familiar with all the miracles of the insect world, were amazed and wist not what to do.

The following are British species of this animal —

*H. viridis* (Polypus Verus of Trembley), is of a green colour.

The body cylindric or insensibly narrowed downwards; tentacles 6 to 10, shorter than the body. It is commonly found in ponds and still waters. The polyps of this species differ from the following only in beingöklikwise in their arms, which are much shorter in proportion to their bodies, capable of but little extension, and narrower at the root than the extremity, which is contrary to the other species; the arms are always green. They have both a very small and slender worm, but seemed to suck it fast till they could master and devour it, which they did
HYD

as with much greediness as any. It was first observed in
Essex in the spring of 1743 by a Mr. Ducane of
Essex. It appears to be a hairy animal, and is easily kept for
a length of time in a phial of water.

H. vulgaris is of an orange-brown or yellowish colour,
body cylindrical, tentacels 7 to 12, as long or longer than
the body. It is found in weedy pools and slowly-running
tidal streams. This does not exceed H. varius in size, which it
resembles also in its habits and form. It is always of an
orange-brown or red colour, the intensity of the tint depend-
ing on the nature of the food, or the state of the creature's
mood. Every part of the body is generative of young,
which may be seen in the female parent at the same
time in different stages of their growth.
H. attenutata is of a light oil-green colour, the body at-
tended below, with pale tentacels longer than itself. It is
found in ponds, and in Yetholm Leugh, Roxburghshire.
This is a species of H. varius, and is rare, but less
notable for external impressions, and of a more
gaudy form. Its colour is a pale olive-green, with paler
streaks, which are considerably longer than the body,
and hang like silken threads in the water, waving to and fro
without assuming that regular circular disposition which
they commonly do in H. varius. Dr. Johnson says he has
not observed more than one young at a time, which pulalitized
from near the middle of the body, and after this has attained
a certain growth, its body, the polyp has the appearance of being
dichotomously divided.

H. oligactis (Polyopes à Long Bras of Trembley) is brown
or griseous; inferior half of body suddenly attenuated;
tails or tentacels are longer than the body. It is found in
still waters in England, rare. In a pond at Hackney, and in
a pond at Crammore, near Belfast, September 1812. The
tails of these are long, slender, and transparent, and when
placed under the microscope a long straight canal may be
seen passing from the body or stomach to an opening at the
end thereof; these are rather lighter coloured than H. vul-
garis, and have seldom more than 6 or 8 arms, those
of great extent. It may be worth while to call attention to the
remarkable resemblance of the Hydra fusco
the Oceanicae cirrata of Müller, which is an intestinal
worm.

(Johnston, History of British Zoophytes; Landborn, Popular History of British Zoophytes; Trembley, Memoires pour servir à l'Histoire d'un Genre de Polyoses d'aujourd'hui, the Hage, 1743; Baker, Natural History of the Polyope.)

HYDRIDE, a family of Snakes belonging to the Cen-
tryside sub-order of Dr. J. E. Gray's arrangement, and the
first section of this sub-order, which includes the Hydrides
and Boa. The latter is thus characterized: with
narrow elongate shields or scales, nearly resembling
those of the snakes.
The following is a synopsis of the genera, and a list of the species. Compiled from the Catalogue of the species of Snakes in the British Museum:

Hyrida.—The ventral shields narrow, hexagonal or
band-like; the hinder lips not developed; the eyes and
nostrils superior, vertical, the latter valvular, generally
placed in the middle of a shield, with a slit or groove to its
outer edge; fangs moderate, intermixed with the maxillary
teeth; papill small, round; tail compressed or conical. They
live in the sea or salt-water lakes, or in fresh water.

Synopsis of the Genera.

1. Tails compressed (except in Acharondr.). Belly keeled,
with two rows of small scale-like shields, often united
in a single, rather broad, 6-sided shield.

4. Head shielded to the nape. Nasal shields very large,
with a large, opacified, superior nostril in their hinder
division; frontal shields two pairs, small; loreal
shield none; labial shields, large, high. Hydrina.

These are the true Sea-Snakes. They coil themselves up
on the shore, and appear to live on sea-weed, and lay their
eggs on the shore. They are often found asleep on the
surface of the sea, where they are easily caught, for they
cannot escape the spilling of the seas, or the spouting
of waves to their backs. This arises apparently from the necessity of
spilling the air from their large lungs. They are often
thrown shoreward in the surf, and are occasionally carried
upstream by the tide, but they cannot live in fresh water.
Their bite is venomous, and they are held in great dread by
fishermen wherever they occur, on this account. In spite of

their venomous properties, one species at least, the Hydrina
(Pelamis) bicolor is said by Cuvier to be eaten at Tahiti.

a. Scales square or 6-sided, placed side by side.
   Head elongate, depressed.

1. Pelamis.
   P. bicolor. Pacific Ocean. For figure see Hryna.
   P. ornata. Borneo.

2. Lopeus.—Head moderate, short, rounded in front;
dorsal scales square; ventral shield broad, 6-sided.
   L. Hardwickii. Borneo.

3. Aturia.—Head moderate, short, rounded in front;
dorsal scales 6-sided; ventral shield 6-sided.
   A. ornata. Indian Seas.
   A. Belcheri. New Guineas.

4. Microcoelophis.—Head small; scales 6-sided; ventral
scales keeled.
   M. gracilis, the Kadal Nagam. Madras.

δ Scales ovate, 6-sided, imbricate, keeled, or with the keel
reduced to a tubercle on the centre of the scales; head
and gape moderate.

   Lateral shields occupying the greater part of the
     lip; the eyes over the fourth, or rarely over the
     third, or the fourth or fifth shield; ventral shield
     united.

5. Enhydrina.—Rostral plates narrow, erect; lower
linear; sunken, nasal rowed in front; ventral shield flat;
head moderate, short; eyes moderate.
   E. Bengalensis. Madras.
   E. Volakadjen. Madras.

6. Hydrophis.—Rostral broad, transverse; lower trian-
gular; nasal truncate or notched in front; ventral shield
flat; head short; eyes small.
   H. obscura, the Shooter Sea. Madras.

7. Chitulia.—Rostral broad, transverse; lower triangular;
   nasal truncate or notched in front; ventral shields flat;
   head elongate, depressed.
   C. tenuorita. Indian Ocean.
   C. fasciata. Indian Ocean.

8. Kerila.—Rostral broad, transverse; lower triangular;
   nasal truncated or notched in front; ventral shield broad,
   convex, forming a slight keeled ridge; the hinder ones with a
   keel on each side; head short, shelving; scales very large,
   broad, 6-sided; eyes rather large, over third and fourth
   labial shields.
   K. Jerdoni, the Kerilia. Madras.

   K. Sherali, the Kerilia. Madras.

   ** Lateral shield occupying the front half of the lip; eyes
   over the fifth or sixth shield; hinder part of the face
   covered with small scales; ventral scales generally
   6-rowed, forming a keeled ridge, some united in pairs
   in 6-sided scales.

   H. major, the Sea-Snake. India; Australia.
   H. annulatus, the Ringed Sea-Snake. Singapore.

   c. Body covered with smooth polished imbricate scales;
   head large as the body; ventral shields rather large, trans-
   verse, smooth, united to the keel, and large and broad.

10. Tomaspater.—Head with regular shields; supernumerary
   shields simple; ventral shields entire.
   T. Eydousi. Indian Ocean.

11. Stephanohydra.—Head shields numerous; supernumerary
   shields 3 or 4; ventral shields nicked behind.
S. fusca, Jukas's Hypotrophis. Darnley Islands.

B. Head covered with scales, like the body; nostrils surrounded by a small, continuous ring; eyes surrounded by a series of small scales; labial shields small, with a larger series above them; pupil round; ventral shields very small, scale-like, separated on each side of a keeled ridge. The species are all inhabitants of rivers.

Acrochordina.

12. Cherthydrus.—Tail compressed, sword-shaped, prehensile; body fusiform, covered with small rhombic scales, with a central tubercular keel.

C. granulatus, the Cherthydrus, Madras. For figure see Hydrops.

C. annulatus. Madras.

13. Acrochordina.—Tail conical, tapering, moderate; body fusiform, covered with tricuspid scales.

A. Jianaxia. Java.

II. Tail conical, tapering. Belly rounded beneath, with more or less broad band-like shields. Rivers or ponds.

A. Head shielded; tail scaly beneath; abdominal shields flat, small, 6-sided, with a keel on each side, as if formed of two united scales; nostrils in a ring of small scales; scales keeled. Erpetonsina.

E. tentaculatus, the Erpeton. [Eenroaw.]

B. Head shielded; tail with two series of shields beneath; nostrils between two shields; abdominal shields broad, keeled on each side; scales smooth. Bikiana.

B. hydroides.

C. Head shielded; scales striated, and keeled or smooth; tail conical, tapering, with two series of shields beneath; nostrils in centre of a large nasal shield, with a groove to the outer side; ventral shields rounded (or rarely slightly keeled on the sides): frontal shields 3, rarely 2 or 4, all small. Cerberina.

a. Crown scaly; occipital rudimentary; frontals 4; anterior pair very small.

C. inauris, the Baroe Bokadam. India.

C. acutus. Borneo.

C. unicolor. Philippines.

C. musculus. Australia.

b. Crown shielded; occipital moderate.

* Head distinct, depressed; frontals 4; anterior pair small; rostral rounded.

17. Feraria.—Scales smooth; seventh upper labial low, with a large shield over it.

F. Siewoldi. Bengal.

** Head distinct, depressed; frontals 3; anterior transverse; rostral rounded.

† Fourth and fifth hinder labial shields small or divided.

H. bicuspis. Java.

H. Hordivitis. India.

P. punctata. India.

+++ Hinder labial large, like others; scales keeled; rostral rounded.

20. Uranops.—Scales truncated, strongly keeled, striated; eye over fourth shield.

U. angulatus. Tropical America.

21. Tachynectes.—Scales truncated, strongly keeled.

T. Leoparctina.

22. Tropidophis.—Scales ovate, keeled, striated; eye over fourth and fifth shield.

T. Schistoma, the Chittee. Ceylon.

23. Myron.—Scales ovate, slightly keeled, smooth.

M. Richardsoni. Australia.

M. trinitatis. India.

24. Helicops.—Scales ovate, polished; of back and tail keeled.

+++ Hinder labial large, like others; scales smooth; rostral rounded.

25. Hypotisina.—Seventh labial large; eye over fourth and fifth labial; loreal distinct.

H. plumbea. Borneo.

H. Hardivitis. Penang.

H. Aer, the Ulak Aer. Borneo.

H. bilunata. China.

H. Bennettia. China.

26. Farancia.—The seventh labial large; eye over the third and fourth labial.

F. fasciata, the Wampan-Snake. New Orleans.

27. Hydro.—The seventh labial large; eye over the fourth labial; ventral shield broad; body thick; loreal none.

H. Mariti. Brazil.

28. Hygrina.—The seventh labial large; eyes over the fourth labial; ventral shield narrow; body slender; loreal none.

H. fasciata. Demerrara.

29. Dimodes.—The seventh labial short, small; eye over third and fourth labial; loreal none.

D. piciculitis. New Orleans; North America.

+++ Head moderate, depressed; frontal 3; anterior elongate erect, between the nasals; seventh smooth; rostral rounded.

30. Furudonia.—Scales broad, rhombic; ventral shield rounded; loreal none; eye over third labial.

F. leucohyla. Timor.

F. unicolor. Borneo.

31. Gerarda.—Scales broad, rhombic; ventral shields rounded; eye over fourth labial; loreal square.

G. bicolor, the Gerard. West Indies.

32. Hippotes.—Scales narrow, flattened; ventral shields keeled at each end; loreal square.

H. fasciata. West Indies.

+++ Head indistinct; frontal 4; anterior 4-sided, rather smaller; scales smooth; body cylindrical.

33. Abatdr.—Body cylindrical; loreal shield none; anterior frontal 4-sided; posterior ocular 2.

A. erythrogena, the Striped-Wampum. North America.

34. Radixia.—Head small, conical; body subcyindrical; anterior frontal very small, triangular; loreal distinct; posterior ocular.

R. Indica. India.

35. Mariosia.—Head small, conical; body compressed; frontal plates 2 pairs; loreal none; posterior ocular 2.

M. alatons. Java.

+++ Head moderate, depressed; frontal shields, 2, small lateral; rostral shield angular, high, erect, between frontal and nasal.

36. Fleiaxia.—Head small; rostral plate large, produced between the frontal, angular and recurved in front.

F. olivacea. Mexico.

+++ Head small; frontal shields 2, transverse, band-like; rostral triangular, subangular.

37. Proptoma.

P. naeoaria. Guinea.

D. Head covered with small scales; tail with one row of shields beneath; abdominal shield broad, rounded, smooth; nostril in a shield, anterior, sublateral; scales granular, with rows of keeled scales. Xenedermis.

38. Xenedermis. J. Xanonicis, the Genionote. Java.

Dr. Gray says, "The separation of the specimens of this family into species and genera is attended with great difficulty; the form and number of the shields of the head, lips, temple, and chin are liable to great variation, not only in the
different specimens, but often in the two sides of the same individual. The two ventral series of scales are, in the same specimen, sometimes separate, and at other times united into a shield; and many specimens have a series of small triangular shields on the edge of the lips, between the stipes of the lip-shield, not found in other individuals of the same species.

* The distribution of the organs on the body appears to be one of the permanent characters of the species; but this becomes less distinct in the older specimens, and is often lost in the specimens that have been carelessly or long preserved in a museum. The existence of this family of Water-Snakes has undoubtedly given rise to the notion that a large Ophiad, which meets the popular view of a Great Sea-Serpent, exists. In all cases however the reports of the existence of such a creature have been traced to the capture or sight of some other animal, or to the exaggerated representations of some other natural object. The Hydroidae amongst the Hydroidea are of comparatively small size, seldom equalling the Boidae in this respect, and falling far short of the enormous dimensions popularly attributed to the Great Sea-Serpent.

** HYDROIDEA. ** [Mineralogy, S. I.]

HYDROCYON, a genus given to Fishes belonging to the Malacopterygi Abdominatae. The species are very numerous. They have the point of the muzzle formed by the inter-vallii, the maxillaries upper, before the eyes, and completing the upper lip. The tongue and vomer smooth, the jaws with conical teeth, and the large suborbital covers the cheek like an operculum. A large number of species inhabit Brazil. They are also found in the Nile.

** HYDROIDA. **

A name given to a section of the order Polyphora, embracing forms resembling the fresh-water Hydra in the simplicity of their organisation. The following is Dr. Johnston's arrangement of the families of British Polyphora referred to the Hydroidea:

1. *Ovira* or bulbules naked, land-like, pollinating from the stipes of the tentacles.

2. *Tubularia*, Ehrenberg (Tubularia, Linnaeus; Tubularia, Linnese; Tubularia, Johnstone; Leu Tubularia, Van Baeended).

3. Family I.—Polytrk naked, or only with a rudimentary polypid: Corynaea.

+++ Polytrk naked.

The tentacular scattered. *Ovira.*

The tentacular in one row. *Hydactilina.*

+++ Polyp with a horny cuticle.

The tentacular with globose tips. *Coryne.*

The tentacular filiform. *Coryphora.*

+++ The tentacular in a single row. *Exudinrnum.*

+++ The tentacular in a double row.

Polyplid rooted. *Tubularia.*

Polyplid unrooted and deciduous. *Corynora.*

** Ovira in the form of horny capsules or vesicles scattered on the polypid, and deciduous.

Family III.—Cells of the polyp sessile. *Sertularidae.*

+++ Cells biseria.

Cells alternate, tubular. *Haliclum.*

Cells vasiform, everted. *Sertularia.*

Cells comico-tubular, appressed. *Thiaaria.*

+++ Cells uniseria.

The branchiata plumose or pectinate. *Pumilulata.*

The branchiata whorled. *Antennulata.*

Cells alternate, campanulate. *Laomedea.*

Cells irregular, or whorled. *Campanulata.*

+++ Polypid propagating by buds and ova, which develop themselves on and in the body of the parent.

** HYDRA. **

Ehrenberg (Hydra, Linnaeus; Hydrara, Johnstone). One genus only. *Hydra.*
valves of the involucres are convex or gibbose throughout, touching only by their edges, which are quite entire. The range of this species seems to be much more extensive than that of its congeners, and it appears to be a taurus species and northern species, and generally to prefer a greater elevation; still the two plants are often intermixed, particularly about the waterfalls in the vicinity of Killarney, and it is very frequently difficult to distinguish the one from the other.

(N. S. & E. F. V.)

HYOSCIA MA. [CHEMISTRY, S. 1.]

HYPERURIC ACID. [CHEMISTRY, S. 2.]

HYPOXIDACE.E. Hypoxis, a natural order of Endogenous, Herbaeous Plants, with tumbous or fibrous perennial root. Leaves always growing from the root and crown, nowhere else, linear entire, plaited, of a dry texture, Scapes simple or branched, occasionally very short. Flown complete, hermaphrodite. Perianth petaloid, adherent to the ovary, 6-parted, with the sepals conser than the petals. Stamens are inserted into the base of the segments of the perianth; filaments distinct; anthers turned inward, 6-celled, erect, opening lengthwise. The number of the plants of this order is very inconsiderable. Those that are known inhabit the Cape of Good Hope, Australia, the East Indies, the tropics of America, and the warmer parts of the United States.

The roots of Curculigo orchoides are somewhat bitter and aromatic, and are employed medicinally in India. The tubers of C. stoechad are eaten in the Marianne islands; those of Hypoxis roscia are employed by the aborigines of North America in healing ulcers and against intermitting.

I

IBALIA. [Galanthum.]

IBRAIL, IBRAILow, or BRAYLOW, a large town in Wallachia, is situated on the left bank of the Danube, 15 miles S. from Galatz, 103 miles N.E. from Bucharest, and has about 20,000 inhabitants. It stands nearly opposite the Turkish fortress of Matchin, and is the chief shipping port of Wallachia, whence the corn and other products of that principality are exported. The town has of late years risen rapidly in extent and importance. Its population in 1836 was estimated at only 6000. The harbour, formed by an arm of the Danube, is sheltered by an island. There are extensive granaries and warehouses in the town. Between 600 and 700 vessels enter and leave the harbour annually. Many of the inhabitants are engaged in the sturgeon fisheries of the Danube. In the wars between the Turks and Russians in the 18th century, the town was more than once besieged and taken by the Russians, who burnt it in 1770. After the peace of Kutchuck-Kainardji in 1774, the town was strongly fortified in the European manner; but the Russians took it again in 1826, and demolished its defences. It was restored to Turkey by the treaty of Adrianople.

INDIAN EMPIRE. The British Empire in India now extends from the Indus on the west to the Tenasserim Provinces and the Eastern India Settlements on the east, and from the Himalaya Mountains and the frontiers of Nepal on the north to Cape Comorin on the south. Under the head Hindostan an ample description has been given of the whole of that great peninsula, including the Punjab, Goojerat, and the island of Cutch. India is described separately [Singh, S. 1.], as also are the Tenasserim Provinces [Tenasserim], and the Eastern Straits Settlements [Malacca; Penang; Singapore; &c.].

The administration of British India is now under the Governor General of British India in Council (who is Governor of the Presidency of Bengal), the Lieutenant-Governor of Bengal, the Lieutenant-Governor of the North-Western Provinces, the Governor of the Presidency of Madras, and the Governor of the Presidency of Bombay. A Return furnished by the East India Company, and presented to the House of Com-
We shall now add the additional historical details down to the present time (March, 1850), in the form of a chronological account, arranged under each of the successive years.

1847.

1848.

April 30. Mr. Vans Agnew and Lieut. Anderson, with a small body of troops, arrived in the city of Moollan on the 1st of April, accompanied by the newly appointed governor-general, Lord Napier. Lieut. Anderson was murdered on the following day, by order of Moolraj, the ex-governor, who immediately began preparations for a war with the British. Lieut. Edwards, who was then on the west bank of the Indus, hastened to join the army with another force. Edwards met the retreating defeated army, till they descended by the western bank of the Indus, while 10,000 troops sent by Moolraj descended by the eastern bank. Edwards crossed the Indus with 3,000 irregular troops and about 800 cavalry, but not artillery, in order to make a junction with the army of the Nawab of Behulpur, leaving Cortalnd to procure boats and bring over the rest of the troops and guns. Before this could be done, the troops of the Nawab were defeated, and Edwards, with his small body of men, was attacked by Moollan's force of 10,000 men and 100 guns. Edwards defeated the retreating defeated army, till at length Cortalnd got over gun after gun, and gradual reinforcements of men. The Sikh forces were then defeated, and fled to the city of Moollan. This was the last battle of which it is necessary to speak. July. Lieut. Edwards and the Nawab of Behulpurpoor invaded the city of Moollan.

August 15. General Whish arrives with additional troops before Moollan, and a bombardment is commenced on the 18th of September.

September 22. General Whish, in consequence of the defection of SherSing with 6,000 troops and a quantity of artillery, is obliged to raise the siege, and take up a position in the vicinity, waiting for reinforcements.

Several various movements by the Sikh forces under SherSing and Chutter Sing, and the British under General Gough and Major-General Thackwell. The Sikhs are driven from an advantageous position at Ramban, by Thackwell, November 2, who again defeats them, December 3, below Vizierabad. December 27. Reinforcements having arrived, the entrenchments of Moollan are again attacked.

1850.

January 18. Battle of Chillianwallah, between the forces under Sir Hugh Googhe and the Sikhs. In this battle Sir H. Googhe attacked precipitately; and though the enemy suffered great loss and retired, the loss of the British was 537, and that of the Sikhs 7,307, and Chatter Sing with a large force of insurgents from Attock. Sir H. Googhe, in his dispatch, said the victory was complete; but the Duke of Wellington and the British government thought otherwise. At this time Sir Charles Napier was appointed to supersede Sir Hugh Googhe as commander-in-chief. January 29. Practicable breaches having been made in the citadel of Moollan, and preparations made for storming, Moolraj surrendered himself and the garrison unconditionally. January 14 to 16 February. After the battle of Chillianwallah there were several movements of the Sikh forces and the British.

February 17. General Whish crosses the Chenab, and, with his forces in communication with those of General Gough.

February 21. Battle of Goojerat. By this battle the brave old Gough retrieved his character and won additional fame. The Sikhs under ObstunSingh and Shere Singh were strongly posted on the village of Goojerat, with 80,000 men and 60 pieces of artillery. The British force was 34,000 men and 97 pieces of artillery. The battle lasted from six o'clock in the morning till five in the afternoon, when the Sikhs were attacked. In the night, the British camp was taken, and the work of some artillery was immediately commenced. They were poured fifteen miles. The two leaders escaped with about 6,000 men into the Salt Range Hills. The final result was that 23 of their guns and all their ammunition were captured.

March 14. Chutter Sing, Shere Singh, and the principal chiefs of the Sikhs, together with 15,000 men of the Sikh army, surrendered, with all their arms and 41 guns, to Major-General Gilbert, at Rawul Pundee.

March 29. Proclamation by the governor-general, announcing the annexation of the Punjab to the British possessions in India. Duleep Singh, the deposed Malah-Raja of Lahore, retires to Poona, on a pension of 40,000l. a year.

May 6. Sir Charles Napier arrives at Calcutta as Commander-in-Chief.

September. Moolraj having been condemned to death in August, for the murder of Agnew and Anderson, is sentenced to transportation for life.

1850.

February 27. Sir Charles Napier, by a general order, disperses the 66th Bengal Native Infantry, for mutiny.

July 2. Sir Charles Napier resigns his office of Commander-in-Chief, and arrives in London, March 19, 1851.

1851.

January 28. Death of Bajee Rao, ex-Peshaw of the Mohrattas, at Bithoor. He enjoyed, by treaties, June 13, 1817, and June 1, 1816, a pension of eight lacs of rupees (90,000l.), a year. Greenwatt Nursee Punk, Nana Sahib, eldest son of Bajee Rao, is domiciled by his uncle as his heir, and on the death of Bajee Rao, claimed the continuance of the pension, which was refused by the Supreme Government of India, and the refusal was confirmed by the Court of Directors.

September 1. Prince of Wales Island, Singapore, and Malacca, formed into a separate government, independent of the Supreme Government of Bengal.

October 29. A British naval force arrives before Rangoon, in consequence of disputes between the government authorities of the Burman Empire and the Supreme Government of India.

1852.

January 4. The victory of Rangoon erects stockades and batteries, to prevent the British vessels from communicating with the shore or leaving the harbour. The British com- modore destroys the batteries, and forces the passage of the river Irrawady.

February 6. Marathas stormed by the troops sent from Hindustan.

April 14. Rangoon stormed and captured by General Goodwin.

October 9. Prome recaptured.

December 3. Pegu invested by a Burmese army. A British force of 4,400 men sent from Rangoon destroys the besiegers, which relieves the siege.

December 30. A proclamation of the Governor-General of India annexes the province of Pegu, which formed a part of the Burman empire, to the British possessions in India.

June 20. Proclamation by the Governor-General of India announcing the termination of the war with Birma.

The Charter of the East India Company, granted in 1833, being to terminate in April, 1854, an Act was passed, August 30, 1853, "to provide for the government of India." The following is the substance of the most important clauses:

August 30. Act 16 & 17 Vict. c. 95. 1. Until Parliament shall otherwise provide, the British territories in India are continued under the government of the East India Company. 2. After April 1854 there are to be only fifteen directors of the said Company, any ten of whom are to form a Council. 3. The Crown is to appoint six of the directors. 9. Six of the twelve elected directors must have resided at least ten years in India to provide for the government of India.

December 11. Death of the Raja of Nagaop, whose territories were then added to the British possessions in India.

May 31. Treaty with Dost Mahomed, who is afterwards re-instated on the throne of Cabul.

February 7. The Governor-General announces by a proclamation the deposition of the king of Oude, and the
annexation of the kingdom of Oude to the British possessions in India. The King of Oude is granted an annual pension of twelve lacs (120,000L.).

For a notice of the dispute between the British and Chinese authorities at Canton, see China, S. & S.

1857.

The year 1857 is sadly distinguished by the mutiny of the native regiments in India. In January, February, March, and April, there were mutinies of single regiments at Barrackpore, Berampore, and Lucknow, which were suppressed; but on the 10th of May the 3rd regiment of Bengal cavalry broke out into open mutiny at Meerut, and was joined by the 11th and 30th regiments of infantry. The mutiny spreading, the authorities of England, General Canning, on the 21st of May, orders the evacuation of Delhi, and the British forces retire to the Residency at Lucknow. On the 22nd, the British forces had entire possession of the city of Delhi.

September 25. General Havelock, accompanied by General Outram, with 3,000 troops, arrives at Lucknow and relieved the Europeans besieged in the Residency, but is unable to force the gates of Delhi.

October 27. Sir Colin Campbell, having been appointed Commander-in-Chief, leaves Calcutta on his route to Cawnpore.

November 3. Sir Colin Campbell arrives at Cawnpore. November 13. Sir Colin Campbell, with about 15,000 troops, commences the attack on the rebels at Lucknow.

November 17. Sir Colin Campbell, after a series of operations and some severe fighting, forces his way into the Residency at Lucknow.

Sir Colin Campbell, having remained two or three days, evacuates the Residency at Lucknow, and by a well-directed feint, brings about the whole of the besieged garrison, with all the sick, the women, and children, without the loss of an inch of ground, to a point where the whole are placed in the hands of Alumbagh, about three miles from Lucknow.

December 7, 8. The Gwalior contingent force having surrendered, under General Seals and the nominal possession of the town, Sir Colin Campbell attacks the Gwalior mutineers, and defeats them.

December 10. The defeated Gwalior troops are pursed by General Hope Grant, with cavalry and infantry, and are completely dispersed, with the loss of the remainder of their guns and all their baggage, stores, and ammunition.

1858.

In the early part of this year various bodies of mutineers are found at different places. In the mean time Sir Colin Campbell at Fathelugar and Cawnpore, having collected troops to the amount of about 20,000 and about 130 heavy guns, commences the siege of Lucknow on the 1st of March. In connection with the troops of Sir James Outram and other officers, altogether, it is stated, amounting to about 50,000 men.

The last mail from Bombay states that the old King of Delhi has been tried, found guilty, and condemned to behead-ment.

Lord Palmerston's late government announced the intention to bring a hill into parliament, for the purpose of transferring the government of British India entirely from the East India Company to the British government, and Lord Dufferin, the Secretary of State for the Home Department, introduced (March 24, 1868) a bill for the same purpose.

Having now brought down the historical details as far as they are known at the present time (March, 1868), we shall give an account of the chief products of British India, and also of the commercial progress which has been made there in recent times.

The products of India are as numerous as its surface is diversified and its climate various. The staple products are cotton, indigo, sugar, hemp, flax, opium; maize, wheat, rice, and other cereals; besides which there are tea, spices, gums, dyestuffs, and many articles of minor note.

Cotton is the leading feature of Indian agriculture. There is little land, save that which is sterile, swampy, desert, or unhealthy, which may not be cultivated; and the soil on which it can be grown. In most of the large lands upon the plain country, it forms part of a two years' course; and outside the village walls, hand-woven have been seen from time immemorial, making the coarse cloth universally worn by the natives. The home-cotton is the fine cotton; it is immense, and geographically its growth is confined to no particular limits in the Indian peninsula, for it is found at Travancore, the southernmost part, on the coasts of Chittagong and Arracan, of the Gulf of Cutch, in the valley of the Ganges, and in the northernmost part of the Panjab. Poor porportion, its principal localities have been the district of Goorjat, in the Bombay Presidency; of Kandahar, in the kingdom of Berar; from Bunderland, in the Bengal Presidency; Belgaum, Darwar, and Bellary, in Mysore, and from the Panjab and Sind, amounting to millions of acres, are stated in the statistical returns, printed by authority, to be under cotton cultivation in the three Presi-
The quantity of raw cotton exported to Great Britain in 1854 was 1,048,336 cwts., valued at 1,641,714£; but it, by means of railroads, the great cotton field of Bihar, situated within the dominions of the Nizam of Hyderabad, was placed nearly on an equality in point of facility of transport, with the maritime cotton districts, then a breadth of land sufficient for the growth of a quantity perhaps equal to the full demand of Great Britain, might at once be made available.

The foregoing conditions relating to the province and prospects of Benares are partly in course of being fulfilled. When the great Indian Peninsula Railway shall be complete, the great rivers of the Belgaum, the Nerbudda, and the Indus, will have an outlet to the port of Bombay on one side, and to Mirzapoor and the river Ganges on the other; and the railroad which is intended to connect the cities and presidencies of Madras and Bombay, will pass through the cotton districts of Bellary and Ceylon. The cotton of Bundelcund, of the Delhi territory, or of Oude, may be seen to this day, uncleaned and unpressed, passing down the rivers Jamna, the Ganges, and the Indus, in unwieldy country boats, which drift no faster than the current will bear them along. Still more to be deplored are the efforts required to convey it in country carts, or upon the backs of bullocks, from the great cotton-field of central India towards the sea-coast, or to the banks of the Ganges. Freedom from the inconvenience of the burdensome nature of the cotton commerce may be seen struggling among unknown roads, extricated with difficulty from the sands of unbridged rivers, and passing at the rate of 10 to 14 miles a day, on one side towards Bombay, and on the other to Mirzapoor, the railway will vastly contribute to the exportation of the article. It is, however, a remedy; and if one line should not be sufficient, they should be multiplied, until the shipments of cotton from Nagpore shall be as certain and as cheaply effected as they now are from Calcutta or from the mouths of the Indus.

Great importance is attached to culture; but the nates of large tracts already employ a mode of cultivating the cotton plant in principle nearly the same as the American, but better suited in some respects to the locality. The great importance which the cultivation of the Indigo and of the cotton plant has in many parts of India, and the situation of this substance in the market, has brought it into great demand in this part of the world—what benefits it has conferred on the soil of the lands—this is, in the way in which it is gathered and stored, and chiefly in the way in which it is separated from the seed, and prepared for the market, as well as in its transmission to market. At the gathering the effort for improvement should commence.

The introduction of improved methods of cleaning and packing is of the first importance. The cultivation has to contend with sundry disadvantages, but those are compensated by the superior character of the produce. It is found that in many parts of India being only 14£ per lb, while in America it is from 50 to 100 per cent. more, ranging from 2d to 3d.

The Indigo is one of the principal articles of produce of the Bengal Presidency. It is grown to some extent in the alluvial soil of the North-Western provinces; but Bengal proper, below the junction of the rivers Jamna and Ganges, is its chief locality. There is a considerable cultivation of the plant in the Madras territory, and in Cochin, the southernmost district of the Panjab, as well as in Sinde; but in none of these countries has the manufacture of Indigo had the benefit of that European superintendence and skill, which have brought this dye to such perfection as it is now in Europe. It is grown in Bengal under a degree of skill which, in a climate favourable to the plant, and backed by the cheapness of labour in Bengal, has enabled them to bid defiance even to the more practised manufacturers of the west. The culture and manufacture, being established, Indigo has continued one of the staple products of Bengal. The quantity imported into the United Kingdom from India in 1854 was 64,964 cwts., valued at 1,464,134£.

Jute-Canvas is another of the indigenous productions of India, from whence it has been supplied to other countries, where, especially in the West Indies, it has been brought, by European skill and culture, to yield a far better substance than the sugar of the country from which it was originally imported. It is styled ‘Jute’ in India, and ‘Jute’ elsewhere; but, with regard to this article of commerce, should not compete with any other country in the world. In various parts, it has soils and climate which are capable of producing the cane in the greatest perfection. In the whole of Bengal, in the North-Western Provinces, the Panjab, in the Madras territories, and on the east side of the Bay of Bengal, the sugar-cane is grown with perfect ease and in the greatest abundance. But, so far as observation goes, the method of propagation of this crop is faulty to a degree, and some of the leading principles of vegetable physiology are set at nought. The cane attains, in some places, a height of eight or ten feet; it has numerous ramifications in its roots, and several long roots; the top produces an extraneous shoot set so close together, that either air nor light can sufficiently penetrate for the proper development of the plant, and the deposit of the full proportion of ascarine matter which is essential to a perfect article. It is said of this plant, with regard to both its cultivation and the manufacture of it, there is more room for improvement, as well as greater prospect of success, than with respect to any other agricultural product of India. A few sugar factories, superintended by Europeans, have been established and are successfully worked, but if one tithe of the attention should ever be paid to sugar in the East, which it has met with in the West Indies, the results to India, as well as to England, would be very great. Already it forms an important article of export from British India, the quantity imported into the United Kingdom in 1854 having been 776,189 cwts., valued at 891,708£. Samples of East India sugar sent to this country have been pronounced equal to any from the West-Indies. But to give the sugar success it is necessary to make it profitable, it is necessary to pay as much attention to the culture of the cane as to the manufacture of the sugar.

The true Hemp-Plant is common to nearly all Asiatic as well as European countries, but is believed to be of Eastern origin. In India, it is grown in many, perhaps the greater part of the districts of the Himalayas, it is not cultivated for its fibre, but for the intoxicating juice it contains, which is manufactured into the delirious drug termed Bhang. In almost every part of India it is cultivated and planted widely, for the better production of which, it is now in great request. Hemp is of great utility to commerce; but, it is remarked, the hemp of the Himalayas is different from that of Russia, Poland, and Italy. The hemp of the Himalayas, a district of the Himalayas, the north of the Panjab, has recently acquired some celebrity, having proved on trial superior in strength to even the best Russian hemp.

There can be no question with regard to the practicability of producing here of a quality suited to the European market, over vast tracts of country on the lower slopes of the Himalaya Mountains. It has been stated, on good authority, that Himalayan hemp may be landed in England, including all charges, at from 2d. to 3d. per ton, and it is said that its value here would be 36£.

But there are other fibres considered as substitutes for hemp, which are received from India, and have become most important articles of commerce. The Bum of Bengal, and Jute, and Gunny, which is manufactured from these, these products are from plants totally different from the true hemp, which has just been described.

Sisam, or Indian Hemp, under which name the article is exported from that country, is the produce of a leguminous or podded plant, and has a close resemblance to the Spanish hroom, which is a sub-division of that order. It is cultivated everywhere in India for its fibre alone; and with this object, the natives affirm, that the thicker it is grown the better it is, on the principle of—'sow thick that the wind be no friend to thine enemy;" which is a proof that, without any acquaintance with the physiological reasons by which the correctness of this system can be shown, they have, by long practice and observation, arrived at the true method of culture. In their treatment of the plant however, after it has come to maturity, they have much to learn, in order that the fibre may be produced in the best state for the markets of Europe.

The fibre of Jute, or Jaw's mallow, has not been till lately an article of commerce; but within the last few years it has been much employed in our manufactories. In India it has been long employed for making both cordage and cloth. The material is obtained from two distinct plants, one of which appears to abound chiefly in India and China, and is termed the Jute Plant; the other, called Jute. The quantity of hemp, gunny, jute, &c., exported from the three Presidencies, but much the largest part from Bengal, amounted in the year 1854 to 570,320 cwts., valued at 200,476£.
Flax, or the linseed plant, has been cultivated in India from its earliest time, not for its fibre, but only for its seed, from which the well-known oil is expressed. It is accordingly sown, not thickly together, as is the case with sunn, which is grown for its fibre, but along the margins of fields of other crops, where the sun and air can freely reach it, and in the same fields from which its seed depends.

But, if in India this plant could meet with some portion of the attention which is bestowed upon it in Russia, Poland, Belgium, Germany, France, Italy, and Ireland, it would, no doubt, become important to India, as it is already so for its seed. The quantity of linseed and flax-seed imported from India into the United Kingdom in 1854 was 196,570 quarters, valued at 601,994.

It has been already stated, that the winters of Hindostan, and certainly of the upper Indian provinces, the north and north-western provinces, are so temperate as to resemble the autumns of Europe. For a season ranging, according to latitude, from October or November to March or April, all trace of the tropical heats seems to have disappeared, cultivation of nearly all the European types occupies the soil. Abundance of wheat and barley are grown in this interval, being sown towards the conclusion of the rains in August or September, and reap'd in April before the heat set in. The wild grasses, too, that spring up amongst the crops, may this enrich the golden corn; not a single hedge marks the boundary of one field from another, nor even of the numerous village lands; and on an apparently interminable level plain, there is nothing to arrest the eye over this rich expanse, save the great trees that mark the entrance to the villages and their wells. No wheat comes from India to this country; but rice, which is grown in vast quantities as food for the inhabitants, is also exported to the United Kingdom; the quantity in 1854 having amounted to 2,851,285 cwt., valued at 875,977.

Allusion has just been made to the introduction of the Tea Plant in India. In 1834 Lord William Bentinck determined upon attempting the cultivation of tea in India. Dr. Rogie, who was sent out by the Government of the East India Company to examine the Resources of India, says: "A committee were then assembled for the purpose of submitting to Government a plan for the accomplishment of this object." But so far back as the year 1827, Dr. Royle had drawn attention to this matter, and pressed it upon the notice of Government. "The tea plant," he stated, "delights particularly in sheltered valleys, the declivities of hills, or the banks of rivers, where it enjoys a southern exposure to the sun. But it is found also to grow on the rugged tops of mountains; and although it appears to attain the greatest perfection in the climate of West Nankin, yet it flourishes in the northern latitude of Pekin, and in Japan, as well as about Canton, and these places are comprised within the parallels of 30th and 40th north latitude." Dr. Royle had observed that the tea of the Himalayas, or at moderate elevations, there was considerable prospect of success in the cultivation of the tea plant; for the different elevations allow of every variety of climate being selected, and the geographical distribution of the plant is sufficiently extended, and the natural sites sufficiently varied, to warrant its being beneficially cultivated. Taking the extreme limit, the Himalayas extend over 45° of latitude, but not making more than 10° of neither in its whole extent. Though the effect of longitude no doubt produces difference in climate, yet as this is chiefly influenced by latitude and elevation, it is evident that along the whole extent of this mountains country, there must be many localities which differ little in latitude and in elevation, and within the same locality the climate must vary, and therefore probably also in vegetation.

In the hills of Assam, the tea plant was found to be indigeneous. Plants also were procured from China, "as well as seeds and cultivators, to carry on the experiment;" and it was resolved that when the practicability of producing the kind of the tea most commending to commercial purposes shall have been ascertained, it may be safely left to the enterprise of individuals. This course has been strictly followed. The Court of Directors, and the Government of India, have consistently exerted their utmost efforts to the successful issue of the tea plant, have handed over its further extension to a private company, who, engaged in the cultivation and preparation of tea in Assam, for the half-year ending the 31st March 1856, amounted to 19,6551.

In the Kohra district, quite at the other extremity of the British territory, still on the lower slopes of the Himalayas, in the Murree Hills, and in Ghurwal, Kumaon, and the Dehra Doon, and Darjeeling, similar successful experiments in tea culture have been made, and annual produce of quality white tea at a price. Its cultivation by the natives has been encouraged by grants of land on favourable terms; but too much is not to be expected of them in this respect, as they will succeed except under European superintendence. It can only, therefore, be expected that tea will be produced over the great extent of the Himalayan range which bounds India on the north, and which contains such important commercial companies, like that which has succeeded in Assam. Besides the Assam Company, another has been recently established for the growth and manufacture of tea in Darjeeling, a part of the Himalayas to the eastward of Nepal.

The iron is in small lumps from one or other of these districts. In the Kumaon Hills, vast beds of hematite iron have been recently brought to notice by Colonel Drum-
mon. Unfortunately no coal occurs, nor is likely to be found within any reasonable distance; but abundance of charcoal can be made from the boundless forests with which the lower slopes of the Himalayas and the plains adjacent to the Ganges are clothed.

There are copper mines worked by the natives in several districts of the Himalayas; but the produce is small, and India has never supplied herself with this metal. Brass vessels are above all use; but copper, spelter, and manufactured brass are imported annually at the principal ports of the three Presidencies, to a large amount. The natives of Hindustan have neither possessed the capital nor the skill to mine deeply, and to abstract the riches which lie buried in their mines. This is one of the greatest misfortunes of the country.

The southern portion of the Tenasserim Provinces, from the province and latitude of Tavoy, to the Pakchan river, abounds with the ore of tin, which is found in the greatest purity in the beds of streams, and in hills of disintegrated granite on the plain. It is a pure perekUse, requiring the application only of a moderate heat to produce the perfect metal. The quantity hitherto prepared in the British territory, can be reckoned only as an indication of what might be obtained if labour and machinery were duly applied to the task. The extent of tin-working which has been carried on in Tenasserim, has not been by the natives of that province, but by the enterprising and more industrious Chinese, who are in almost every case the only miners of tin that can be seen dotted here and there in the forests. They have a smelting establishment at the mouth of the Pakchan river, and the tin is carried away in junka to Pananag and Sagain.

It is an article of manufacture in India almost exclusively for domestic consumption, the value exported being insignificant.

Sufficient has now been said of the most independent industries of India, to show in what her real wealth and value to England consist;—above everything, it has been intended to prove that, in comparison with the actual produce of her soil, all else sinks into insignificance when we contemplate the resources, or endeavour to ascertain the material progress of that country.

There is no step which has a more direct bearing on this subject than the irrigation of the land by artificial means. There are traces in various parts of the country of works constructed in ancient times for this purpose. Canals and reservoirs have been in India long known and useful. The discharge could be regulated and distributed when the ground was parched. It has been commonly and with some justice remarked, that to furnish the native cultivator with the command of water is to give him nearly everything he wants. It is now properly brought to the notice of the world.

The East India Company, following the example of the Moguls, their predecessors in the government of the country, have greatly extended the means of irrigation in the North-Western Provinces, in the Panjub, and in the Presidency of Mysore.

With regard to irrigation canals, the waters of both the Jumna and the Ganges rivers have been freely drawn upon. The country on the right and left banks of the Jumna, from Susanger to Allahabad, and even south of Allahabad, may be said to be secure against drought, cultivation now, over a large surface, being entirely independent of the periodical rains. The Eastern Jumna and the Western Jumna Canals, with their branches, are 450 miles in linear extent. The volume of water available for irrigation from this river, has been calculated at 8,370 cubic feet per second, and each cubic foot has been found adequate for the annual irrigation of 315 acres of land; but as one-third of a district only is necessary, the needs of the Ninghal and the Jumna canals will be exceeding, one cubic foot of water per second will suffice for 654 acres of land, equal to about one square mile, so that the canals of the Jumna are supposed to serve for the irrigation of 3,870 square miles.

The Jumna is still nobler work. Nearly the whole tract of country comprised between the rivers Ganges and the Jumna, from Hardwar to Allahabad, is included in this large system of irrigation for the North-Western Provinces. The main line of this canal, which was completed, and received water for the first time in 1854, in 856 miles in length. Its extreme breadth is 170 feet, and its greatest depth 10 feet; and, as truly described by the Lieutenant-Governor, "it is a work which stands unexceeded in its class and character among the wonders of the world." In the time of its construction, it shall be finished the canal will be about 900 miles in length, and the area which may be irrigated by its waters is stated to be not less than 1,470,000 acres. It is adapted also to navigation. No sizable canal in Europe has attained to half the magnitude of this Indian work. It nearly equals the aggregate length of the five greatest canals in France. It greatly exceeds all the first-class canals of Holland put together, and it is greater by nearly one-third than the greatest navigation canal in the United States. It stands thus as one of the greatest triumphs of the engineering art of which any country can boast. Its total estimated cost is 1,666,648/, or of which 1,400,000/ had been expended up to the beginning of the year 1857.

In the Panjub a system of similar canals has been projected and partially commenced, to afford the means of irrigation to the greater parts of the tract of country comprised between the rivers Ravee and the Sutlej. With the branches, the total length when finished will be 450 miles, and the cost 500,000/.

The head waters, like those of the Ganges and Jumna canals, will be taken from the rivers at a high level, and carried along the slightly elevated ridge which is generally found to exist between two rivers, having a gentle declivity on each side, and so designed as to be suited to the country. But towards the southern part of the Panjub, at and below Mooltan, and on each bank of the Indus, another description of irrigation canal prevails, which has been formed by taking advantage of the annual inundation of the rivers. The waters of the Indus are collected in the Godavery, the Cauvery, and the Krishna rivers, so as to store up their waters and distribute them at pleasure during the dry season. These works on the Godavery have cost about 950,000/., on the Cauvery 60,000/., and on the Krishna 150,000/., and, notwithstanding the number of the localities are endless, both in that Presidency and in various other parts of India, where similar works might be constructed with the greatest advantage.

Next in importance to the future progress of India, and in a still wider sense than may yet be known, not only with regard to its material interests, but to its social and moral advancement, is the continuous chain of iron roads by which it is hoped, that before many years shall have passed, the whole of the Indian Empire will be linked together. The natives of every class and caste, contrary to general expectation, unimprovable of any prejudices, living together in the same railway carriage, have seized with avidity the advantages of the locomotive train in Bengal, Madees, and Bombay. The opening of the railway for short distances at Calcutta, and the two other Presidencies, has been hailed with acclamation by the whole people, who flocked from their villages for miles to see the progress of the works.

The grand trunk lines now in progress of construction are of great extent. From Calcutta the main line will lead through the entire valley of the Ganges, for a thousand miles to Delhi, with an eventual extension, in the same general direction, across the river of the same name, to the Kandershe, Saugor, and Bundelcund, branching into the great cotton-field of Central India to Nagoop, and affording an easy outlet for that valuable product, either to be shipped at Bombay, or for conveyance down the river Ganges, from Mirzapoor to Nagpur, and from the Nile to the Bengal. At Miliase is a still nobler work. Nearly the whole tract of country comprised between the rivers Ganges and the Jumna, from Hardwar to Allahabad, is included in this large system of irrigation for the North-Western Provinces. The main line of this canal, which was completed, and received water for the first time in 1854, in 856 miles in length. Its extreme breadth is 170 feet, and its greatest depth 10 feet; and, as truly described by the Lieutenant-Governor, "it is a work which stands unexceeded in its class and character among the wonders of the world." In the time of its construction, it shall be finished the canal will be about 900 miles in length, and the area which may be irrigated by its waters is stated to be not less than 1,470,000 acres. It is adapted also to navigation. No sizable canal in Europe has attained to half the magnitude of this Indian work. It nearly equals the aggregate length of the five greatest canals in France. It greatly exceeds all the first-class canals of Holland put together, and it is greater by nearly one-third than the greatest navigation canal in the United States. It stands thus as one of the greatest triumphs of the engineering art of which any country can boast. Its total estimated cost is 1,666,648/, or of which 1,400,000/ had been expended up to the beginning of the year 1857.
Indus, which seems to be a first step towards a direct rail-way, or mixed railway and river steam communication, from the Panjib to the sea. In the Presidency of Madras, two trunk lines are projected: one to penetrate the peninsula in a longitudinal direction, and to connect Bombay, passing through some rich cotton ground in Darwar and Belgaum; the other to strike across to the western coast, having its other terminus at Bombay. At the beginning of 1837 the number of miles of railway already opened for traffic at the three Presidencies, and the extent of each line actually in a state of progress, are as follows:—

When these grand trunk lines of railway shall have been completed, a glance at the map will show that, although the richest parts of the peninsula have not been penetrated, the principal cities connected, the 3,926 miles of which they consist, are but the foundation and groundwork of what will be ultimately required, before it can be said that India is completely provided with communications; before, in fact, many of the inlying districts can be supplied with food, when their own internal resources may fail.

Inland steam navigation has existed for several years on the river Ganges, and also upon the Indus; but not by any means to the extent which even the private traffic of Bengal and the Punjab requires.

The ordinary highways of India is a subject which cannot be regarded with much satisfaction. Until the period when Lord William Bentinck governed the country, the subject of roads does not appear to have attracted much attention from the State. The communications of the country were in a most neglected condition, consisting of native wheel-tracks, or little else. Above Allahabad, and in various other parts, a regular system of roads, a regular arrangement in country, of relief from one station to another, had to be proceeded by a native guide. This is now altered. Roads, even if unbridged and unmetalled, exist in almost every district; and there are three grand lines of communication of considerable length; the earliest begun only in 1836, from Calcutta, and recently prolonged to Peshawur: this, however, is not yet complete in parts.

The three grand trunk roads constructed and maintained, are as follows:

The average annual expenditure upon public works of all kinds in India during fifteen years, between 1837 and 1852, was 289,732l. In this are comprised roads, bridges, embankments, canals, tanks, and all works of irrigation; but since 1856 the outlay has been much greater, including the sums spent upon the Ganges and Punjab Canals, and the guardianship interest upon Railway Stock, which must be regarded as a contribution to public works.

The electric telegraph, which has been recently established with so much rapidity and success, can scarcely be regarded as a public work. As nearly upon the wants and welfare of the people, as other public works which have been briefly described. Except inasmuch as it is an aid to good government and to the preservation of peace, the rapid transmission of intelligence from any part of the country to the other, is as yet slightly regarded by the native community, but when traffic shall be accelerated by the railways, it will not be long before the telegraph will be rightly valued. More than 4,000 miles of telegraphic wire are now set up in India, and in constant use. The superintendent, Dr. O'Shaunessy, availing himself of the executive officers of Government throughout the country, to set up the posts and to build pillars for the support of the wires, and with his own trained engineers, has enabled the public service to be established from England, was enabled to complete the communication between Calcutta and Agra, a distance of 800 miles, in the course of five months. In fifteen months, all the lines from Calcutta to Agra, and from Bombay, and the lines behind over 2,000 miles of space, were ready for use. Other places more distant have since been embraced in the electric circle, and the average cost of these 4,000 miles does not exceed 560l. per mile, although the physical obstacles encountered have been great.

INDIAN TERRITORY, United States of North America, an extensive tract of country set apart by the Congress and federal government, for the permanent residence of the various tribes of native Indians removed from the settled states and territories of the United States, is an area, in which it lies generally, 9° 30' and 39° N. lat., 94° and 100° W. long., but the limits are not very strictly defined. It is bounded S. by Texas; E. by Arkansas and Missouri; and N. by the newly created Territory of Kansas. The area, as given in the "Reports of the Census" of 1860, is 157,171 square miles, but this is considerably more than in previous statements of the area of what is sometimes called the Indian Territory proper, and perhaps includes a portion of the country since appropriated to the State of Kansas.

In the south-eastern portion of the Territory, there is a range of hills of moderate elevation; the remainder is a plain, or ma
doubtedly the southern portion of the country, is a large district of prairie ground, but along the rivers there is a good deal of timber. The country is well supplied with water, having several good-sized rivers running through it or along its borders on their way to the Missouri and the Mississippi. The Aransas flows through the southern portion of the country, and across the southern boundary, and receives in its passage numerous tributaries, some of considerable size. The chief of these tributaries is the Canadian River, which also has numerous branches. Its right fork, the Red River, wanders the southern and the Kansas the northern portion of the state; both of these, as well as the Arkansas, are navigable within the territory at certain seasons by steam-boats. The country possesses capabilities for the prosperous maintenance of a large population. The middle, and by far the largest part of the country, appears to belong to the Lower Carboniferous series of rocks. On the east are Upper Carboniferous strata, or coal-measures, a part of the great coal-basin of Missouri and Illinois. The western and northwestern districts belong to the Grand Canyon series, and the belt of Lower Silurian rocks, consisting along the Red River of blue limestones, with impure rocks. Coal is not the only mineral. Both lead and iron are found; and there are large beds of salt springs, which might be made use of for the manufacture of salt. The climate is generally healthy. The northern parts are subject to keen westerly winds from the Rocky Mountains, and the winters are rather cold; but in the southern parts the winters are mild, and all the plants are cultivated which are raised in other parts of the United States of the same latitude. The soil on the eastern side of the Territory is generally fertile; the northern parts are well adapted for grazing cattle. Wheat, maize, and other grains, produce good crops in almost every place where they have been tried.

As already said, this large tract of country has been appropriated for the permanent residence of the Indian tribes transported from the settled parts of the United States. It was regarded as a good test of the capabilities of the country. But they have shown that they are capable of steady industrial efforts, and they have made very considerable advances in civilization. Under the guidance of missionaries, who have settled amongst them, and with the sanction and concurrence of the Commissioner of Indian Affairs, some of the larger tribes have established regular governments, legislatures, judicial officers, churches, schools, newspapers, &c.; have introduced the manufacture of agricultural implements, cloth, and most articles of ordinary domestic use, and have set up trading posts, with a considerable amount of skill; rear horses and cattle; build houses; and export to neighboring states maize, cotton, hides, &c. By the treaty of removal and settlement, the federal government furnishes them with blacksmiths, wheelwrights, and some other mechanics, and at their settle,
The principal Indian tribes settled in the Territory are the
Cherokees, who numbered according to the Commissioner of
Indian Affairs, about 17,600 in 1853, but whose numbers are
usually estimated much higher; the Chicksaws, with about
4,900; the Creek, 16,000; the Choctaws, 4,941; the
Chickasaws, 4,797; the Pottawatomies and Chippewas, 4,680;
the Pawses, 4,500; the Seminoles, 3,000; the Sacs and
Foxes, 2,737; the Shawnees and Senecas, 1,400; Delaware, 1,130, &c.
The Cherokees occupy the whole of the eastern part of
the north of Arkansas, and adjoining the state of
Arkansas, and are the most civilized of all the Indian tribes.

The Chocktaws occupy the most southern point of the
territory between the Red River and Canadian River. The
Chickasaws, whose territory is about as great as that of
the Choctaws, is settled by two tribes, one of which
inhabits the northwestern part of the state, and the
other the southeastern. The Creek, the most populous tribe
in the state, occupies the whole of the northwestern part
of the state, without distinction of races, and are
composed of various tribes, 

1. The Capitolium. The undeveloped axis is here nearly
enlarged upward, with a feathery or spongy substance, and
the more so if the number of flowers is very great. It may be
more minutely designated as simple, double, capitate, lageno-
form, conical, and cylindrical, as it approaches nearer to
one or another form. The cap or one part of the cap
passes gradually into the epixis. 

Special varieties are:—

* The Calathium (Anthodium, Ehrh.; Flora Composita,
Linn.), a many-flowered capitulum, whose single flowers
stand in the axis of more or fewer stunted bracts, and are
surrounded with one or more circles of sterile bracts, as in
the family of the Compositae.

** The Cenanthisium, Nees (Hypanthodium, Link.).
Exactly like the preceding inflorescence in some
Urticaeae.

1. The Cyme, defined by the shape of the peduncle in
Ficus is no distinction, except in those which is
wider than the peduncle; and it exists in some
Dorstenia, the Cymetium, the Cymetum, and the
Composita, and some others.

*** The Spadix, Bickel, the simple inflorescence of the
Grasses and Cyperaceae; namely, a few-flowered spike,
whose flowers have no bracts, surrounded with the same,
or two stant bracteae (Gymnophyllum).

2. The Umbel (Umbellifera) when
compound termed an Umbellula (Umbellula) 6.

3. The Raceme (Racemum) occurs in very different forms;
usual to distinguish in it—

The Cymetum (Corymbi), a pyramidal raceme.

β Inflorescentia Centrifugae.

5. The Cyme or False Umbel (Cyme), is a corymb
with Inflorescentia Centrifugae.

That only singular cases are distinguished in these is a
proof of the totality of scientific patching together of our
terminology. The compound raceme, the compound umbellum,
and capitulum, with inflorescentia centrifugae are all called
the Cyme (Cyme), which is contrary to the commonest scientific
laws. De Candolle has a different appellation for the same Cyme
Inflorescentia centrifugae, and he adds the fiction, that the
undermost first-blooming flower is really the terminal
blossom, and the second, the terminal blossom of side axis, is developed in a
disproportionate degree, &c. From the rolling up there is
just as little to be deduced as from the same phenomenon in
the leaves of Ficus and Oxalis. The position of the
bracts, as seen in Ceratost, contradicts this fiction; and the
history of the development, which can alone determine the
point, appears to prove that here a one-sided raceme or spike
is present, whose unrolling is only a peculiar situation of
the kinds.

C. Once-Compond Inflorescence.

a. Pure or Homomorphic

** Inflorescentia Centrifugae.

6. The Spike of the Grasses (Spica), several spikes united
in a spike-like arrangement, as in the Grasses; the component
spikes are termed Spiculae (Spiculae).

7. The Umbel (Umbellula). Umbels united in umbels; the
components are termed Umbellae (Umbellae).

Sound terminology would have long ago rejected these
words, and exchanged them for Spica and Umbella Compo-

4. The Solitary Flower, as terminal or axillary-flower (Flo-
Solitaria, terminalis vel axillaris). The latter may be
situated in whors, and then form a Verticil (Verticillus).

B. Simple Inflorescence.

* a. Inflorescentia Centrifugae.
10. The Anthela; see No. 16.

* Inofficiens Centrifuga.

See No. 14.

** Inofficiens Centripeta.

See No. 11.

D. Many-Times-Compound Inofficiens.

* Inofficiens Centripeta.

11. The Panicule (Panicula), every many-branched information of apples universally, and otherwise wholly in developed pedicels. 12. The Thyrs (Thyrsus), a panicule, with very short pedicels; with the exception of Grasses, found almost universally.

Both terms are applied also to once-compound inflorescences. De Candolle uses the term Thyrsus for those in which Inofficiens Centrifuga and Centripeta are mingled; others differently; all arbitrarily.

13. The Anthela, an inflorescence that has the kind of aspect of that of the *Amoranthus caudatus* or the Cephemiales.

** Inofficiens Centripeta.

14. The Cyme (Cyma), also in manifold combinations, in which however we do not consider whether the side ramifications follow the Inofficiens Centripeta or Centrifuga in longer pedicels.

15. The Bush (Fasciculus), a manifold compound cyme, with pedicels, and rather crowded.

16. The Anthela, all kinds of inflorescences in the Juncoceae and Caryophylaceae.

The Glomerules (Glomerules) many inflorescences that appear almost like capsulaceae, and consist only of ill-formed, imperfect flowers, as in some Chamomilaces, Urticaceae, and Juncaceae.

We subjoin Professor Schleiden's closing remarks:—

I leave every one with thinking faculties to draw for himself the sad conclusions which the preceding survey affords; and I think that I have not to defend myself to any one who is acquainted with our literature, against the charge that the foregoing is a frivolous vagary of my humour. Köper first attempted a scientific development of the inflorescence.

No one that I know of has followed him, except Lindley. Physiologists seem not to have accounted it of sufficient importance. Systematists have too much to do with their herbaria, and it is much easier to coin a new word than to study intelligently the processes that have produced them in a large numbers of species. For the sake of those unacquainted with these matters I will insert the following examples:—In *Lotus corniculatus*, Koch (*Syn. Fl. Germ.*) has a Capsulatum, Kunth (*Fl. Berol.*), an Umbella, Reichenbach (*Fl. excurs.*), and *Eryngium corymbosum* to *Entherium eorymbosum* Kunth, gives a Spica; Koch, a Spicula. For *Cladosium Maritimum* Kunth has Umbella Axillares et Terminalis; Koch, Anthela Axillares et Terminalis; Reichenbach, Cyme Axillares et Terminalis; *Icelpus subfasciatus* Koch has Spicula in Fasculatum aggregatum; Kunth, Spica Conglomerata. I have here omitted the French and English botanists, or the matter would have been still more glaring.

INFUSORIA. At the time the classification given under the names of the above groups was drawn up, the distinctions that limit the vegetable and animal kingdoms were less perfectly understood than at present. One of the first members of this group of organised beings that was withdrawn from the animal kingdom was the Dendrocysta, which are now generally recognised as plants. [Dendrocysta, S. 2.] The group of *Paraspidoptora toricata* must also be placed amongst doubtful creation, although many physiologists do not hesitate to group them amongst plants [*Diatomeeae*, S. 2.], whilst the groups *Monadina*, *Volvocaceae*, and *Paludicula* have recently undergone the most searching investigation, with the result that many of these forms are more decidedly vegetable than animal in their character. Some have even gone further than this, and have deduced the *American Journal of Science*, for 1832, thus writes to Mr. Dana:—"You may remember a paper read at the meeting at Cambridge, United States, in August 1843, in which I showed that the embryo which is hatched from the egg of *Platyrus* is a genuine polygastric animal.
ment and evolution of a Tricodium, a discovery which Ehrenberg has attempted to explain by the supposition that the Microscopium, or Infusoria, resembles the shell of an animal which to its own accommo-
dation has its bluish color seamed upon its sides with brown and orange. Dr. Stein's important researches are continued through the family of the Vorticellina, and his observations given upon 

Actinophrys, Polyphaga, the genus Tricodium, and on the nature of the Oligonema, the propagation of the Chloronema and of the Polysiphonum, the body of which is a single cell or an aggregation of cells, which derives its nutri-
tion by absorption from without. Professor Kohler has recently described the method by which one of these bodies, the Polygastrica of the Polyzoa, was studied. The case in question was of great interest, and it was observed

"As regards the vegetable functions," says the Professor, "the mode in which the Actinophrys is nourished is one of the highest and most special interest. Although the creature has neither mouth nor stomach, yet it takes in solid food, and rejects what is indigestible. This marvel, for so it may almost be called, is thus effected with minute Buccinatum (Kolli-
ker, minute species of Lymnesa, the young of Cyclops, &c.), and the lower Alga (Diactonema, spots of Vauxoula, Clastotetra, &c.), which in its progress through the water it approaches and in the act of attack seizes and compresses. When an Infusoria or Vorticelle is in contact with it, both plant and animal, as soon as they touch one another, the tentacular filaments, usually adhere to it. Now, as the filaments with their prey slowly shorten itself, and the latter appears to be devoured. The body of the 

infusoria is gradually thrown out to the extent that the filaments apply themselves upon itself, bending their points towards the animal, so that the captive becomes gradually inclosed on all sides. According to all appearance these filaments also become more or less shortened. In this way the morsel is gradually brought to the surface of the body, the principal by which it was seized, being finally so much shortened as to disappear altogether, and having, as not unfrequently happens, relinquished its hold upon the prey, after the latter has become encompassed by the surrounding filaments. These gradually apply themselves more and more closely together around it, forcing it towards the sur-
face of the body.

The following account now takes place: The spot of the surface upon which the captured animalcele is lying slowly retracts, and forms at first a shallow depression gradually becoming deeper and deeper, in which the prey, apparently adherent to the surface and following in its retract

ion, is gradually lodged. The depression by the continuous retraction now extends into the imprisoned animalcele, which up to the time had projected from the surface of the Actinophrys, disappears entirely within it; and at the same time the tentacles, which had formerly rushed out, are forced to surround it, again

erect themselves and stretch out as before. Finally, the depression acquires a flask-like form by the drawing in of its

margin, the edges of which coalesce, and thus a cavity closed on all sides is formed in which the prey is lodged. In this small cavity remains for a longer or shorter time, gradually

approaching the central or nuclear portion, and at

last passing entirely into it, in order to await its final de

structive. In the mean while the external portion of the

infusoria recovers its pristine condition.

The enucleated morsel is gradually digested, and is readily seen by its change of appearance from time to time. If entirely soluble, as for instance an Infusoriaumin, the space in which it is contained contracts as the dissolution of the bodies and final disappearance of the object. Should there be however an indigestible residue (a membrane composed of cellulose, a portion of chitin, a shell of a

Lymnesa, or case of a rotifer, &c.), a passage for its exit is formed, and it is expelled by renewed contractions of the Homogeneous, the eduction in the cavity, and the diameter of the vessel contracting as before, so, as that which the morsel followed in its introduction.

The passage and the opening through which the expulsion was effected disappear again without leaving any trace."

The characteristic point in the Actinophrys, and in the Vorticelle, is the existence of the creature which inhabits the shell of the large family of Foraminifera, and Dujardin suggests that the foraminiferousiferous forms are transitions to the more decided forms of Foraminifera. Hence he proposes to include several forms of Ehrenberg's Infusoria, with the Foraminifera or Polyclamia, under the term

Hydroidea. Little therefore is left to say of what may be regarded as true Polygastrica. They all appear to have a distinct mode of life, and it is found in the cavity of the body, and this is usually surrounded by vibratile cilia, and is seen in Monas atomos and Leucophora patale. These cilia ap

parently bring the food to the mouth of the animal. An anal orifice is described by Ehrenberg in the majority of the Polyclamia. With the name of Monas at atomos, or carmine or indigo (a writer in the "Microscopical Journal" recommends the red pigment which lines the cornes of the common house-fly) is introduced into the water in which they are contained, the trans-parent body of the animalcelle is speedily seen to be stained with color, and portions of the ciliate appear to resemble an aggregation of the particles of colouring-matter. Ehrenberg regarded these globules as distinct sacs, which he supposed were given off from a central intestinal canal, as seen in Leuophorus; and he supposed that in many stomachs, he gave them the name of Polygastrica (many-stomached). It is however still a question as to whether in any case these masses are contained in a distinct sac. The whole body of the animalcelle is often covered with vibratile cilia, and it is to the constant action of these organs that the varied movements of these animalcelles are due. The movements thus effected are perfectly automatic, and in no way connected with any intelligent conscious

ness. All the movements of these organisms are not due to cilia, as the whole of the tissue of the animalcelle is capable of contracting to contract in Amoeba, Amphipitus, and the stalk of the Vorticelle.

— Although Ehrenberg has described a complicated apparatus and the retraction of the instanter contents and cilia, it is amongst the true Polygastrica. Their modes of multiplica

tion are by fission and gemmation. In a large number of cases a simple division of the unicellular organism into two equal parts takes place. This process goes on so rapidly that, according to Ehrenberg, a single Foramensculum could produce 268,000,000 of cells in a single month. From ana

logy we must suppose this process would not go on continu

ously, and, as in plants, we must regard the separate cells thus produced as belonging to the same individual. Further observation is probably only needed to demonstrate the existence of a union of two cells—a sperm cell and a germ cell—as is now known to be almost universal in the vegetable kingdom. In the account above given of Stein's researches it will be seen, that it is not improbable that the manner of the modes by which these beings are enabled to spring suddenly into existence, is the production of winter-eggs, or reproductive bodies of a kind that will resist the influence of an absence of moisture from the spots in which they ordina

rily abound.

The true Polygastrica seem universally diffused. Where the organic matter exists in a decomposing state, there they abound. They exist in incredible numbers in the waters of the ocean, in rivers, lakes, ponds, pools, and ditches. They have been found in the liquid of the stomachs of man in man. Wherever the organic elements, carbon, hydrogen, nitrogen, and oxygen, are capable of uniting to form water, carbo

natic acid, and ammonia, there they may be expected to be found. The composition of the liquids in which they are found, seems to determine the forms they assume. One set of forms inhabits salt water, another fresh. Every mineral
ACTED, called dissolved itsology distinguished dal 1821, in career the tit devoured numerous nance organic Infusoria, for animals, and inorganic destruction inflammatory and's ions and assimilate. Surely we must in some degree be indebted to those ever-active invisible scavengers for the salubrity of our atmosphere. Nor is this all: they perform a still more important office in preventing the gradual diminution of the present amount of organised matter upon the earth; for when this matter is dissolved or suspended in water, in that state of comminution and decay which immediately precedes its final decomposition into the elementary gases, and its consequent return from the organic to the inorganic state, those material mechanical and and's ions of the police are everywhere ready to arrest the fugitive organised particles and turn them back into the ascending stream of animal life. Having converted the dead and decomposing particles to living tissues, they themselves become the food of large Infusoria, as the Rotifers, and of numerous other small animals, which in their turn are devoured by larger animals, as fishes; and thus a pabulum, fit for the nourishment of the highest organised beings, is derived from the extremity of the realms of organic matter.

"There is no elementary and self-subsistent organic matter, as Buffon taught; the inorganic elements into which the particles of organic matter pass by their final decomposition, are the products of decomposed animal and vegetable kingdom. No animal can subsist on inorganic matter. The vegetable kingdom thus stands, as it were, between animal thought and its ultimate destruction; but in this great office of plants must derive most important assistance from the Polygastric Infusoria. These invisible animulacra may be compared, in the great organic world, to the minute capillaries in the microcosm of the animal body, receiving organic matter in its state of minionest subdivision, and, when in full career to escape from the organic system, turning it back by a new route towards the central and highest point of that system."

INGHIRAMI, CAVALIERE FRANCESCO, a distinguished Italian archaeologist, was born in 1776, at Volterra in Tuscany. From the completion of his education he devoted himself with unwearied diligence to the study of ancient art. He wrote several papers in the artistic and antiquarian journals of the day; procuring for him a high standing in art authorities; but the work which acquired for him a European reputation was the splendid publication entitled 'Monumenti Etruschi,' of which the first part appeared in 1821, and which was finally completed, in 6 vols. 4to, in 1826. This great work was intended to comprise a complete survey of all the existing remains of ancient Etruria; and it has formed the great treasury of all subsequent writers on Etruscan antiquities and the Etruscan people. His other works—see Lettere Etrusco-Francese, 8vo, 1868-69; 'Galleria Omerica,' 3 vols. 8vo, 1852 & 31, work intended to illustrate the 'Iliad' and 'Odyssey' by the monuments of antiquity; 'Pitture di Vasi Fintili esibite dal Cav. F. Inghirami,' 4 vols. 4to, 1830-37, in which it was his avowed object to illustrate the mythology and the history of the ancients; and 'Storia della Toscana, in Sette Epoca distribuita,' 16 vols. 13mo, 1841-43, the last two volumes being devoted to the bibliography and index. He also wrote many papers and papers on particulars in archaeology and history in the 'Archivio Italiano,' & Cavalier Inghirami was for several years keeper of the Laurentine Library at Florence. He died on the 17th of May 1846.

INGLIS, SIR ROBERT HARRY, Bart, many years M.P. for the University of Oxford, was the only son of Sir Hugh Inglis, Bart, formerly chairman of the East India Company. He was born in 1786, and received his early education at Winchester, and Christchurch, Oxford. Soon after taking his degree, he became private secretary to the late Viscount Sidmouth, and was appointed by him one of the commissioners for settling the affairs of the Carnatic. In 1834 he entered parliament as member for Dundalk, a borough at that time in the possession of the Earl of Donoughmore. In 1838 he was elected for Ripon; the representation of which borough he resigned in the spring of 1828, in order to contest the University of Oxford against the late Sir Robert Peel, when the latter accepted the Chiltern Hundreds on irregular grounds. In 1839, when the Earl of Donoughmore retired, the post of sheriff of the county of Meath became vacant, and Sir Robert, who had a very strong feeling in favour of the Irish National party, took it, and held it for five years, and during that time he continued to represent the University until January 1838, when he retired from parliamentary life, and was sworn a member of the Privy Council. His public life was one of those devoted to the interests of the country which it is the lot of few to accomplish, and his name is henceforth associated with that of his ancestors in the estimation of the people of Ireland. In 1849 he was appointed junior solicitor to the Athenaeum, and in this position he continued till 1851. In the year 1849 he published 'The Irish National Question,' a collection of a series of articles being his observations on the Irish question. In 1850 he died in England, at London, on the 2nd of August, and was buried in the churchyard of St. Bride's, Holborn, on the 8th of August. In 1851 he was elected for the borough of Banbury. The seat had long been filled by a representative of the Duke of Bedford, who, however, died some years before, and the representation of which borough he continued to represent on behalf of the City of London, and was re-elected in 1852. He was also re-elected in 1853 and 1854, but in 1855 he resigned his seat, having been defeated in the last election. In 1856 he retired from public life, but continued to reside in London till his death, on the 30th of October, 1860. A memoir of this gentleman will be found in the 'Quarterly Review', vol. 109, p. 216. An injunction or an offence either at Common Law or by Statute (7 & 8 Vict. c. 34.) INJUNCTION, in Chancery. One of the recent improvements in the procedure of the Courts of Equity, consists in the abolition of the distinction between Common and Civil Law. An injunction is not now thought of as it was formerly, merely as a matter of course. Sufficient primae facie grounds must be stated in all cases before it will be granted, thus in effect making all injunctions proceed on a basis of proof.

INJUNCTION, at Law. The Common Law Procedure Act, 1834, among other improvements, has enabled the Superior Courts of Common Law to grant warrants of injunction after action brought, in order to restrain the repetition of conduct injurious to the plaintiff. This is sufficient self-complaint, or because no such way avoiding the necessity of a return to the Court of Chancery. This process is, it will be observed, of very limited application, an injunction being generally sought to prevent an injury, and not the repetition of one. INNS OF COURT AND CHANCERY. A report on the present state of those societies was laid before Parliament in 1856, by certain Commissioners appointed to examine into the nature of the legal education thereby afforded. This report being however in many respects erroneous and founded on insufficient information, and its conclusions, nothing has as yet been done towards carrying out the recommendations of the Commissioners.

INSITE. [CHEMISTRY, S. 2.] INSOLVENCY. The Commissioners of the Court for the Relief of Insolvent Debtors no longer make circuits through England, to hear the petitions of prisoners confined for debt in the country districts. This branch of the jurisdiction of the Insolvency Court is now exercised by the County Court Judges, to whom the petition and schedule of the prisoner are for that purpose transmitted. The County Court Judge exercises the same authority as the Court in London, in his decision being final and conclusive. (10 & 11 Vict. c. 105.) See also below. INTRUSIONS. [See below.]

INTESTINES. The structure of the coats of the intestines has been most carefully observed by means of the microscope. The minute structure of the intestines corresponds to a considerable extent with that of the skin—which is the stomach. There are however differences of structure especially in the mucous coat of the intestines. We shall describe first the muscular structure, and in doing this we shall follow Professor Kólliker in his 'Manual of Human Histology.' The muscular coat of the smaller intestines is somewhat thicker in the duodenum and the upper portions, thins in the lower; it has in general a thickness of 2—4 mm, and is composed only of longitudinal and transverse fibres. The former are the innermost, and do not continue continuously, since they are very few or entirely absent along the attachment of the mesentery; they are usually most distinct upon...
the free border, though even here they may be readily torn away with the serrate membrane, so as to leave the second layer exposed. The latter is complete and continuous, consisting of circular bundles, which not uncommonly anastomose at very acute angles.

In the large intestines the longitudinal fibres are reduced to the three ligaments of the tube, muscular bands of 4°—6°, or even 6° broad, and 1°—3° thick, which commencing upon the edges of the submucous layers. Occasionally these bands are longitudinal fibrous layers, thinner than in the small intestines, and more especially developed in the duplicatures, which are known under the name of the plicae semilunatae.

All these ligaments have an imbedded network of muscular fibres. Many of them present knot-like enlargements and frequently zig-zag flexures, which produce the transversely striated appearance of the entire bundles of such muscles so frequently met with in spirit preparations. The arrangement of the fibre-cells in the different strata is simply this, mutually applied in their length and breadth, and coherently. They are united into thin muscular bands, which when invested with a coating of connective tissue, and frequently also united into second and third strata, constitute thicker or thinner muscular tunics of the different regions; which, again are surrounded and separated from the contiguous parts by considerable layers of connective tissue.

Blood-vessels are abundant in the smooth muscles; and they form a characteristic network with rectangular meshes. Nothing is known about the lymphatics; nor are the relations of the nerves yet ascertained, except that Ecker has observed the division of fine nervous tubules in the muscular tunics of the large intestines.

The mucous membrane of the small intestines is thinner than that of the stomach, but more complex in its structure, inasmuch as besides the tubular, or Lieberkühnian glands it presents a great number of permanent folds. The mucus membrane is also imbedded in its submucous, circular, but not longitudinal fibrous layers, the so-called submucous and Peyser's glands, and, in the submucous tissue of the duodenum, Brunner's glands. The mucous membrane consists of connective tissue which is internally homogeneous, and the detached or divided glands exist there is but little submucous tissue, so that it is pretty closely connected with the muscular tunic. Upon the inner surface of the mucous membrane there rests a cylinder epithelium, whilst externally towards the submucous tissue it is bounded by a layer of smooth muscle, discovered by Brücke, which measures at most 0'017°.

They are disposed longitudinally and transversely, but in man their slight development renders it often very difficult to discover them.

The villi of the small intestines are small elevations which can be seen, even by the naked eye, and which are therefore readily distinguishable with the naked eye, and which distributed upon and between the villus convolutes through the whole extent of the small intestines, from the pylorus to the ileum, of which every part is clothed. Besides these, together as to give the mucous membrane its well-known velvety appearance. They are most numerous (60 to 90 upon a square line) in the duodenum they are broader and less elevated, resembling folds and laminae y°—1° in height, 1°—2° or even 2° in breadth. In the jejunum they appear for the most part to be conical and flattened; frequently they are even foliated or cylindrical, or filiform, the latter forms predominating in the ileum. The length of the villi is from m°—n°, the breadth from y°—1°, or even 1°, the thickness in the flattened forms is b°.

The villi are composed of two portions, a deeper cost b) containing the mucus membrane, and an epithelial superficial cost. The contour of the former, or villus proper, is similar to that of the entire villus; it is simply a solid process of the mucus membranes containing blood-vessels, lymphatics, and smooth muscles, whose matrix, through which a vascular system of the villi in different varying strata exhibits no morphological peculiarity more decided than that of the mucous membrane itself, yet must most undoubtedly be regarded as a metamorphosed connective tissue without any of the epithelial characteristics that the villi are so numerous that when well injected those whose epithelium has been detached become coloured throughout; and in living animals, or in those which have just been killed, each villus if viewed from above appears as a red dot surrounded by a clear ring. In man every villus contains a close network of capillaries of 0'003°—0'005°, with rounded or elongated nuclei, which lies immediately beneath the homogeneous external layer of the matrix, and is supplied by one, two, or three small arteries of 0'015°—0'010°. The blood is usually carried back directly into the larger trunks of the submucous tissue by a vein of 0'020°, which does not arise as in animals, by the arching round of the artery, but proceeds from the gradual confluence of the finest capillaries. The villi have not hitherto been perfectly made out; for although the majority of investigators are inclined, like the older observers, to suppose that they commence by one or two conical branches, and that they arise from the vessels of the mucous layer, it is not certain that in many cases only a single lacteal, which has a conical and frequently enlarged end, and whose diameter is much greater than that of the capillaries, traverses the villus. It is in all instances true that the villi have a filiform or cylindrical and filiform villi will be found to present this condition, but that, on the other hand, the number and mode of origin of the lacteals may possibly be different in the broad and foliaceous forms.

In addition to the villi, the organ also contains, as Brücke discovered a short time ago, a thin layer of longitudinal smooth muscles, situated more centrally round the lacteals; these however are not always distinct in man, they produce contractions of the villi, which are very evident immediately before or after death, and are produced by the small lacteals, or vessels external to the villi, in the living animal. They have in all probability an important influence over the propulsion of the chyle, and of the venous blood in the villi—always supposing that there is no object to the villi, that is, that the villi are not the place for the performance of any digestive contractions during life. Nothing is known about the nervous system to the villi. The epithelium of the villi and of the rest of the surface of the mucous membrane, although it is very intimately united with the deeper-seated parts during life, only becomes detached by the few external fluids, and may only be found in the dead subject, and can only be observed in perfectly fresh portions of the intestine. It consists everywhere of a simple layer of cylindrical cells slightly narrowed below of 0'015°—0'012° in length and 0'004° in breadth, whose contents are usually nothing but fat granules, and an oval, clear, vesicular nucleus, provided with one or two nucleoli. During life, these cells, which agree in all their chemical characters with the deeper cells of the oral epithelium, are so intimately united, that even in the best preparations of epithelium, as yet seen, they either not at all or only indistinctly distinguishable, though on the surface they have the appearance of a beautiful mosaic. The cylinders only become quite distinct when they are either spontaneously or artificially detached, and may then be observed in the same manner that they hang together in continuous portions, all the cells covering a villus sometimes coming off together like the epilayer of a moss.

The addition of water to these cells produces a separation of the cell contents from the broad end, giving rise, in separate cells, to the appearance of a membrane thickened upon one side, and, in series of cells or entire villi, to that of a peculiar structureless coat, like the cuticle of plants; by its elongation, however, or by that of the intestine, the bursting of the cells produces apertures in them, or they become distended into large pyriform clear vesicles.

We may here refer to the changes which the epithelial cells and the villi in general undergo during digestion. The most striking circumstance is the occurrence of a fat-glomerulus in different parts of the villi, which may always be observed during the formation of a fatty milk-white chyle. The succession of the morphological steps is as follows: — The fat contained in the chyle at first enters only isolated epithelial cells, but finally the whole villus becomes filled with fat, and consequently bright and shining, with those which are empty and pale. In the end all the cells become filled with these drops, and the epithelium appears quite dark by transmitted, but whitish by reflected light, giving its aspect to the whole villus.

digested on, between walls of the mucous membrane, and agree by

digested at the extremities, though hardly ever dichotomously divided. The best idea of the number is obtained by viewing the mucous membrane either from above or in vertical section, under a low power. In the former case we see the cocca standing close together, almost like palisades, but in the latter they do not occupy the whole surface, but only the interstice between the villi; here however they exist in such numbers as to leave no intervale of any width, the mucous surface being all appearing pierced like a sieve. Even on Peyer's patches, as on the solitary follicle, these glands are to be met with; but in man they leave those portions of the mucous membrane which lie immediately over the crypts of villi free, and therefore are arranged like wings around them.

The length of the Lieberkühnian glands equals the thickness of the mucous membrane and varies from 3″—4″; their breadth is 0″289—0″036″, that of their aperture, 0″185—0″008″, composed of a delicate homogenous membrana propria, and of a. simple epithelium, which even during chylification never, like that of the intestine, contains fat; their cavity is filled during life by a clear fluid secretion, the so-called intestinal juice, which however becomes modified and thickened by contact with the foodstuff, so that the glands appear to be filled with cells, or with a granular mass.

The most important of the closed Follicles are Peyer's patches (glandulae aminativa). They are rounded flattened organs, invariably situated in the mucous membrane, which is opposite the mesentery; they are most distinct upon the inner surface, where they appear as rather depressed smooth spots, without any very sharp definition, but they are also recognisable from the exterior by the slight elevation to which they rise, by the more transparent or more opaque portions of the membrane. These patches are usually the most abundant in the ileum, but they are not uncommonly to be met with in the lower part of the jejunal to the duodenum, and even in the interior horizontal portion of the duodenum itself. Ordinarily there are 20 to 30 of them; but when they are found higher up there may be as many as 60 to 60, but they are always most closely set in the lowest portion of the ileum. The dimensions of the separate patches are in general the larger the closer they are to the cæcum; their length is usually 0″6—1″1, but may diminish to 0″5, and increase to 0″5—0″6, or even 0″1; their breadth from 0″3 to 0″5, or even 0″1. The villi of the valvulae conniventes are usually interrupted; in the jejunum however these folds are also to be met with upon the Peyer's patches and in the ileum; rows of closely-set villi often take their place. More minutely examined, every Peyer's patch is seen to consist of large villi of 0″3—0″5″ in diameter, either rounded or slightly conical towards the intestinal cavity, which lie partly in the mucous membrane itself, partly in the submucous tissue; and are on the one side not more than 0″05″ distant from the mucous surface, while on the other they are in immediate contact with the muscular tunic, which here somewhat more closely united with the mucous membrane.

Villi from the interior of the intestine their most striking feature is man is the presence of many small rounded depressions 0″4—0″5″ apart, which corresponds with the separate follicles, and whose floor is indeed rendered slightly convex by the latter, but which present no villi whatever. The remainder of the patch is occupied by common villi, or by resculated folds, and by the apertures of the Lieberkühnian glands; the latter are disposed around the slight elevations produced by the follicles in cicles of 6 to 10 and more apertures, the coruscular tubulum of stroma.

The structure of the follicles resembles the separate elements of Peyer's patches so closely in size, contents, and general structure, that there is no reason for considering them as distinct, particularly as the number of follicles is considerable in the small intestine of animals at least, we find Peyer's patches with 2—3—5 follicles. In man, as all writers justly agree, their number is excessively inconstant; sometimes not one can be found, whilst in other cases the whole intestines, as far as the mucus of the ileo-colic valve, is thickly beset with them; or, lastly, they may occur in the ileum and jejunum, but in no very great number. Their entire absence must probably be considered abnormal, since they are constant in newly born children, being more abundant in the jejunum than in the ileum. The solitary villous however, which are often met with in immense quantities in the small intestines and stomach in celiac affections of the alimentary tract, may very probably be entirely or partially pathological, since the occurrence of such cases has not been demonstrated in other organs also (in the liver according to Vorhöf). The solitary follicles have the same structure as the elements of the patch, only they occur also in the mesenteric border, and support villi upon their intestinal surface, which is usually somewhat convex.

Professor Kölliker expresses himself as decidedly opposed to the notion that the follicles of Peyer's patches have any apertures. Of their functions he says: They and the follicles of the jejunum in general seem to be nothing but glandular organs, analogous to the splenic follicles, the tonsils, and the lymphatic glands, which contain peculiar elements and a vascular network. In these a constant development of cells takes place, and at the same time substances are decomposed, and perhaps also from matters not of a fatty nature, absorbed from the intestine, a part of which in all probability is at
his uncoloured. Bodemaal.

Visits Stomach the sensation. Hydrous this. A are. was. This was a plain officer of artillery, Isabey had been on terms of friendship with him, and when the empire was founded Isabey continued in favour, and was appointed miniature-painter in ordinary to the emperor. In this capacity he accompanied Napoleon I, the emperor, the young king of Rome his son, the members of the Bonaparte family, and the favourite courtiers and generals. Among the most famous of the imperial pictures was a "portrait of a large slab of porcelain, representing Napoleon I and the most illustrious of his generals, and known as the 'Table des Maréchaux.' Besides the portraits, he executed several court and ceremonial pieces, one of which, a 'Visite de l'Empereur à la Manufacture d'Arbalâtre,' is a picture of the highest excellence, and quite admirably executed with the direction of works relative to the coronation of the emperor, when he was named officer of the Legion of Honour.

On the first abdication of Napoleon I, Isabey accompanied the empress Marie following her to Venice, where he painted a large tablet of 'One of the Conferences at the Congress of Vienna,' chiefly remarkable for the faithful likenesses of the numerous important personages assembled. On Napoleon's return from Elba, Isabey repaired to Paris, and propitiated the emperor by presenting him with a miniature of himself which he had just painted at Vienna. The restoration of the Bonbons brought no loss of fortune to Isabey; but a picture which he exhibited at the Salon in 1817 of 'A child playing with Flowers,' caused some 'sensation' among the Parisians, from the child, who was holding up a bunch of forget-me-nots, bearing a striking resemblance to the young Napoleon. The 'Constitutionnel' having ventured to make a pointed allusion to the likeness, received a warning from the police. Isabey soon after accepted an invitation to the court of St. Petersburg, where he painted the emperor Alexander, the empress, the grand-dukes Nicholas and Michael, and many of the magnates of the court. On his return to Paris he painted the portrait of Louis XVII., and as long as he continued to paint he found ample occupation; his sitters, it is said, having included most of the sovereigns, as well as a large proportion of the most distinguished personages, of Europe. Isabey survived till the 16th of April, 1856. He may be said to have formed a new school of miniature-painters in France. His likenesses have much character, and are generally esteemed faithful. His style is marked by force as well as delicacy, but almost necessarily from the numberless works he executed, also by a good deal of mannerism.

ISARIA, a genus of Fungi, belonging to the division Trichospororia, and the tribe Iaresis of Lévêlile. It is characterized by a compound, solid, capitulated, or elongated receptacle. The species are found parasitic upon caterpillars and the larvae of various insects. Rohin enumerates the following species:

1. Eleuteroborus has been found upon the Carabidae in the autumn of the year.
2. Fascites, upon the larvae and chrysalides of Bombus Jacobea.
3. Strigosus, upon the chrysalides of Notus Upson.
4. Arachnomphus, upon small spiders belonging to the genus Geosora, in the autumn.
5. Leprosus, upon the chrysalides of Notus instabilis.
6. Tornaria, observed by Robin on an unknown spider, in the autumn.
7. Crossus, upon decaying chrysalides.
8. Lychnus, upon a dead hornet.
9. Elycela, upon the larvae of a moth.
10. Araneaceus, an American species, found on spiders in Carolina.
11. Pneumonotus, also found in America, upon the caterpillars of the silk-worm moths.
12. Giganteus, found upon a Mygale in the island of Cuba.

ISEWORTH. [MIDDLESEX.]

ISMAIL, a strongly fortified town of Turkey, in the province of Silistria, is situated on the left bank of the northern or Killia arm of the Danube, 20 miles east from the mouth of the Pruth, and about double that distance from the Black Sea, in 40° 21' N. lat., 28° 50'E. long., and has about 20,000 inhabitants. It was taken by storm by the Russians under Suwaroff, Dec. 29, 1790, when the Turkish garrison numbering 30,000 men were put to the sword; the Russians lost 20,000. Under the Turks Ismail was important, not only in a military but in a commercial point of view; it contained 17 mosques, a large number of khans and bazaars, and many splendid houses. On its capture by the Russians all was put to fire and sword, and the town remained in a ruinous condition till 1812, when it was ceded to Russia by the treaty of Bukharest. Since then it has been rebuilt, and now contains about 2500 houses and 12 churches. The Killia arm of the Danube is navigable for steamers and for vessels of considerable burden, of which about 150 enter the harbour of Ismail annually, and are chiefly engaged in the corn trade. There are remains of a fine Turkish palace in the town.

Ismail is now chiefly of importance in a military point of view, and the Russians rendered its defences very strong. It was restored to Turkey after the late war in the Crimea, by the new adjustment of boundary consequent on the treaty of Paris of 1856.

ISONANDRA, a genus of Plants belonging to the natural order Spermatoz. It is distinguished by the stamens being all fertile, and twice as numerous as the lobes of the corolla.

J. Gutta (Hooker), the Gutta-Percha Tree, has its leaves on long stalks, obovate-oblong, with a short point golden beneath; flowers axillary, fascicled; stamens 12. This tree is a native of the Malayan Archipelago.

The substance yielded by this tree, and designated by the name of Gutta-Percha (pronounced ' Pertaha') is, like Caoutchouc, a carburet of hydrogen, and isomerous with that substance, and possesses a great number of the properties which characterise India-Rubber [Caoutchouc], but exhibits certain special properties which admit of its being applied to particular uses to which caoutchouc is not adapted. Gutta-Percha possesses as great an indestructibility by means of chemical agents as caoutchouc. It has an intermediate consistence between that of leather and wood; it is capable of being softened by heat, and of regaining its primitive consistence on cooling. It is therefore at the same time capable of taking and of retaining the most delicate impressions. The important uses to which it has been lately applied are only the forerunners of those to which it will be adapted hereafter, a scarcity of this precious material (which unfortunately is produced in much less quantities than India-Rubber, and in localities much more circumscribed) does not present an obstacle to it.

Whilst the plants which furnish caoutchouc abound in the whole of the territorial zone which extends between the tropics, the Isonandra Gutta is the only tree which yields Gutta-Percha. It grows scarcely anywhere except in certain parts of the Malayan Archipelago, and up to the present time has been almost exclusively obtained from Singapore. It was brought for the first time into England in the days of Tradescant, as a curious product, under the name of Musar-
JACK, a common name of the Fresh-Water Pike. [Esox, S. L.]

JACOB'S LADDER. [Polemonium, S. 1.]

JAMAICA. [Chemistry, S. 2.]

JANIPHA, a genus of Plants belonging to the natural order Liliaceae. It has a glabrous, oblong, acuminate, 5-parted; petals wanting; stamens 10 in the male flowers; filaments unequal, distinct, arranged round a disc. In the female flowers the style is scabrous; stigmas 3, consolidated into a rosy mass; capsule 3-coccos.

J. Manelot (Jatrophca Manelot of Linnena) is a native of Brazil. It has an oblong tuberous root, as big as a child's hand, full of a wheyish, venomous juice. The stems are white, brittle, having a very large pith, and several knobs standing out on every side like warts, being the remains of the foot-stalks of the leaves, which have dropped off, usually 6 to 7 feet high, with a smooth white bark; branches crooked, and have on every side near their tops leaves irregularly placed on long terete pedicels, broadly-cordate in their outline, divided nearly to their base into spreading lanceolate entire segments, alternate at both extremities, dark-green above, pale-green beneath; the midrib strong, prominent below, and there yellowish-red; from it there branch off several oblique veins, connected by lesser transverse ones; stipes and pedicels short, thick, brown; filaments, or compound racemes, axillar, and terminal, 4 to 6 inches long, bearing sometimes all male or female flowers, at other times these are mixed on the same peduncle; pedicels with small subulate bases. Male flowers smaller than the female. Calyx purple, on the outside, fulvous-brown within, cut out half-way down into five spreading segments; disc orange-coloured, fleshy, annular, 10-rayed; stamens 10, alternate with the lobes of the disc; filaments shorter than the segments yellow, or brown; stigma 3, reflexed, furred and plaited, white; capsule ovate, 3-cornered, 3-coccos; seeds elliptical, brown, shining, with a thick fleshy funiculus. The expressed juice is dangerously poisonous. Felons of the root harmless when separated from the juice and exposed to heat. It is called Cassava. Cassava, the principal article of diet in South America. The nutritious substance known as Tapioca is the Cassava differently prepared and granulated. These preparations are obtained by scratching the roots after the bark has been removed and straining off the water, when the mass is gradually dried in pans over the fire.

JARROW. [Dorham.]

JASMINUM, a genus of Plants belonging to the natural order Oleaceae. It has a tubular 6 or 8-lobed calyx; a 6 or 8-parted corolla; stigmas 2-lobed or bifid; berry dry, globose, having one of the lobes usually abortive; seeds without albumen. The species are usually twining shrubs. Leaves simple or compound; petioles articulate; flowers white or yellow.

J. Sandea, Single-Flowered Arabian Jasmine, is a twining plant; the leaves almost sessile, membranous, from cordate to oblong, acute or obtuse, glabrous; berries globular; branches, petioles, and peduncles downy. It is a native of the East Indies. The flowers generally form small trichomes, umbel-like, without fragrance. The berries are black. A perfume, known as Oile of Jasmine, is obtained from this plant.

J. angustifolium, Narrow-Leaved Jasmine, is a native of the American coast. It is a twining bright plant, with ovate leaves, and a shining deep-green colour. The flowers are large, white, with a slight tinge of red, star-shaped, having a peculiar but very pleasing fragrance. The bitter root of this species, ground small and mixed with honey, is used in India as a valuable external application in cases of ringworm. The plant being constantly covered with leaves of a bright deep-green, sometimes as small as those of Box, render it always beautiful, and well adapted for screening windows and covering arbours in warm climates.

J. officinale, Common Jasmine, is a native of the South of Europe. It has opposite leaves, pinnate; leaves ovate-acuminata; buda eroticum. The plant is glabrous, the branches angular. Calycine segments 6, subulate; corolla white, 4 or 5-cleft, sweet-scented; the terminal leaflet is the largest. The Common Jasmine has been a favourite plant in the Indies, not only for the sake of its perfume, but also because of its beauty; as well as the date of its introduction, are unknown. Gerard in 1597 says it was in common use for covering arbours. There are golden and silver-edged leaved varieties of the Common Jasmine, as well as a double-flowered variety.

J. grandiflorum has opposite pinnate leaves, leaflets bluntish, the outer ones 3 to 6-confluent, buds horizontal. It is a native of the East Indies, and greatly resembles J. officinale, except in the size of the leaflets, and in the exterior ones being confluent, and the flowers larger and reddish underneath. Both this and the former species yield the true essential oil of jasmine of the shops.

The leaves of J. undulatum are slightly bitter. The root of J. succulentus is thought to be elecctric.

JATROPHA, a genus of Plants belonging to the natural order Euphorbiaceae. It has monocious flowers; 4-parted or lobed calyx; corolla 5-parted or absent; stamens 8 or 10, with unequal mounadelpus filaments; styles 5, bifid or capitate; fruit in the shape of a capsule; seeds with a thick yellow rind.

J. Carcusa, Physic-Nun, is a very common small tree, bush, or coast of Coromandel. The bark is smooth and light ash-coloured; leaves scattered, stalked, broad, cordate, 9-angled, smooth, about 6 inches each way; petals rounded, smooth, 4 to 6 inches long: stigmas abortive; panicles terminal or from the exterior axils, bearing many small yellow flowers. The male flowers at the extremities of the ramifications on short articulated pedicels, and the female flowers in their axils, on thick fleshy pedicels. Bracts, a small one below each subdivision of the panicle, and generally one pressing on the calyx; calyx 5-lobed; corolla 5-petalled, campanulate, somewhat hairy; disc of 5 glandular bodies round the base of the filaments; filaments 6, the central one very thick, columnar, the 5 posterior ones filiform towards the base, adhering to the central one, all erect, and a little longer than the calyx; anthers 10, sagittate, equal; 5 supported by the large general filament, and 1 by each of the others. The leaves are rubefacient irritated; warm and rubbed with castor-oil, they are applied by the natives of India as poultices. The seeds are violently emetic and dractic; their expressed oil is reckoned a good application in itch and herpes, and also, a little diluted, in rheumatism. The juice of the seed is an excellent in the case of wounds; healing: it dyes linen black. The oil, boiled with oxide of iron, forms a varnish used by the Chinese for covering boxes. In large doses the seeds are emetic poisons.

J. glauca is found in Arabia Felix. It has leaves from 3-lobed, macronate serrate, toothed; petals naked; stig- pules palmate, with sessile or branched divisions, glindar at the apex. The seeds yield a stimulating oil recommended by the Hindoos as an external application in cases of rheumatic and paralytic affections.

J. glandulifera is a native of the East Indies. The leaves about the extremities of the branches are alternate, petiolated, and generally palmate; the lobes from 3 to 6, oblong, serrate, with each serrature ending in a short green glandular-beaded bristle; stigmas bristly, many-cleft, each division ending in a glandular head; panicles terminal, about as long as the leaves. Male flowers most numerous and terminal, small, of a pale yellowish-green colour. The female flowers few, and sessile in the divisions of the panicle. The pale yellowish, or whey-coloured juice is one of the most fresh and most popular as a medicine is employed by the Hindoos as an escharotic to remove films from the eyes.

J. multifida is a native of tropical America. It has palmate the 11-lobed, macronate serrate, toothed; petioles naked; stig- pules sessate, multifid; flowers corymbose, scarlet, with coloured pedicels. The seeds are one of the best of all emetics and purgatives, acting briskly, but without inconvenience; their effects are readily stayed by the administration of a glass of good white wine.
J. Marsh is now referred to the gena Jäniska. [Janu-
ary, S. 2.]

JAY, REV. WILLIAM, was born on the 8th of May
1769 at Tisbury, Wilts. His father, who was the son
of a small farmer, worked as a stone-cutter and mason, and
young Jay's first employment was that of a mason's boy.
While he was at school, under the tuition of Mr. Cornelin
Winter of Marlborough Academy, an institution
connected with the Congregational body, in which young men
were trained for the ministry. His abilities soon became
known, and he was placed in the Greek class at the age of
sixteen.

For about a year he officiated as the minister of
Lady Maxwell's Chapel at the Hotwalls, Clifton; and on
January 31st, 1791, he was settled as pastor of the church
assembling in Argyle Chapel, Bath, a position which he main-
tained for a period of six years. Mr. Jay retired from
the pastorate in January 1833, and died on the
27th of December in the same year, at the age of eighty-four.

His reputation as a preacher was very high, and was by no
means confined to his denomination, that of the Fede-
pedents. His published sermons have had extensive
circulation, and many a congregation throughout the kingdom
has often listened to Jay's sermons without knowing to whom
they were primarily indebted for the instruction they were
receieved. He became piece of pastor and his labours were
also in the family, and so well adapted for reproduction in
other pulpits, was their simplicity of style, combined with a
clear and methodical statement of the lessons sought to be
conveyed. The effect of his own ministrations was much
enhanced by his manner of delivery, a full command of his
pleasing vocal powers. Mr. Jay's regular con-
gregation was large, and visitors to Bath usually repaired
to his chapel to hear him preach. He generally made an annual
visit to London, and to the coast, where he delivered his ser-
mons elsewhere he attracted crowded congregations. When he
had completed fifty years of his ministerial labours his people
held jubilee services, in connection with which, at a public
breakfast in the Assembly Rooms on the 2nd of February
1839, an edition of music, consisting of 350 copies, were
presented to Mr. Jay. Besides his sermons, of which
several editions have been published, Mr. Jay wrote an
'Essay on Marriage'; 'Memoirs of the Rev. Cornelius Win-
ter'; 'Memoirs of the Rev. John Clark'; 'Lectures on
Female Scripture Characters' (published since his death);
and an 'Autobiography', from which and other sources a
memor of Mr. Jay was prepared by the Rev. Dr. Redford
and the Rev. J. A. James, and published in 1844. A uniform
edition of Mr. Jay's works was published under the author's
superintendence in 1845-49 in twelve volumes, post octavo.

JEFFREY, FRANCIS, was born in Edinburgh, on the
3rd of October 1775, in the upper part of a house now
marked No. 7, Charles-street, George-square. His father,
George Jeffrey, was one of the deputy sheriffs of the
City of Edinburgh; his mother, Henrietta Loudoun, was the
daughter of a Lanarkshire farmer. They had a rather numerous
family, Francis being the eldest son, though not the eldest
child. At the age of three he was sent to the High School
of Edinburgh, where he was for four years under the care of one
of the under-masters, Mr. Luke Fraser—a worthy man, whose
celebrity depends on his having, in three successive classes,
three pupils no less famous than Walter Scott, Jeffrey, and
Brougham. Jeffrey's classical attainments were, while he was under Mr.
Fraser, used afterwards to remember him as "a little clever,
auxious boy, always near the top of his class, and who never
lost a place without shedding tears." From Fraser's class, he passed, in regular course, in the year 1791 to that of the
reverend Dr. Adam Smith, who was the author of the" system of
society" and noted alike for his scholarship and the simple integrity of his
character. Jeffrey, as well as Scott, used afterwards to speak
with the highest respect of this old good man. It was in
the winter of 1786-7, while still attending Dr. Adam's
class, that Jeffrey, then a boy in his fourteenth year, and
post Burne. He was walking along the High Street, when he
was attracted by the appearance of a man on the pavement,
who, as he passed, was so much in manner, seemed to be from
the country, but in whose face was something
uncommon. It was Burns, then on his first visit to Edin-
burgh; and as "the little black fellow was gazing at him,
one standing at a'shop-door near said to him "Ay, laud's ye no look at that man; that's Robert
Burns!" " Jeffrey never saw Burns again; but he used to
dwell with pleasure on the incident.

In the winter of 1787, Jeffrey (his mother being then just
dead) was sent to the University of Glasgow; his father
for some reason or other preferring that university to the
University of Edinburgh. Here he attended the Greek
classes under Young, the logic class under Jardine (then recently
appointed, but already with something of that reputation as a
teacher which he afterwards maintained and increased),
and the economy class under the Rev. Dr. Arthur, the successor of the philosopher Reid. That he did
not also attend the law class, though taught by the able
and eloquent Miliar, is accounted for by the fact that his
father's opposition to the study of law was continued to the
same time as that of his eldest brother, and Jeffrey, like
tory, and likely to regard the teaching of a Whig like Milar
with suspicion. Jeffrey's class-fellows at Glasgow remem-
bered him afterwards as being there one of the cleverest
of the younger students, somewhat 'petulant' in his manners,
and 'melancholy' in his disposition. Mr. Jeffrey was
in his winter on his upper lip in spite of remonstrance
and ridicule. It was in the debating societies of the college
however that he first broke on his companions of that day in
the full display of his superiority. He was a fluent
and rapid speaker, a ready and ingenious writer, and
a merciless critic of the essays and opinions of others. It was
at this time also that he commenced the habit of reading and
versatile reading, and of noting-taking and essay-writing for
his own improvement in the performance of his duties.
On the 7th of January 1789, Jeffrey was accorded the great
ammonition after his removal from Glasgow back to Edin-
burgh in the year 1789. In his little room in his father's
house in the Lawmarket, he read and wrote continuously,
filling quires of manuscript with notes and abstracts from
books, and was concerned in a part in the editing of the Speculative.
Jeffery's friend Lord Cockburn gives a list of 31 different manuscript
essays on literary and metaphysical topics, all written by him
between November 1789 and March 1790. About the same
time he attended the first session of the University of Edinburgh.
In 1791 he went to Queen's College, Oxford, intending to complete his studies there.

While at Oxford he was very solitary and melancholy; he
disliked the place; and after nine months was overjoyed to see
his sister, Johna, and his friend during his stay at Oxford, "I see nothing that it
is possible to acquire in this place." On his return to Edin-
bwich, in July, 1792, his friends found that his stay at Oxford
had altered him in at least one thing: he now as long
spoken in his former natural Scotch accent, but in a sharp
and, as some thought it, an affected English style of pron-
cunciation. "Jeffery," Lord Holland used afterwards to say," had lost his broad Scotch at Oxford, but he had gained
only the narrow English." Very soon however his friend,
who knew his real intellectual force and the genius
good of his heart, became reconciled to his new style of speech;
and Lord Cockburn certifies that to his latest years, Jeffrey
had never really forgotten his native Doric, but could talk
brother Scots and Galwegian, as the habit of the countrymen
when he chose. He had a strong relish, too, for
Scottish anecdotes and humour. For a while after his
return from Oxford, it seemed uncertain whether he might
not be called upon by his father to give up the law;
but he came a merchant; but the legal profession was not
extinct

On the 19th of December 1792 he became a member of the famous
Spectaculat Society, then at the height of its fame; and then
he first formed the acquaintance of Scott and many other
young men of the day. This distinction as lawyers, literary men, and statesmen.
For several
years Jeffrey was one of the oraments of this society, reading
essays in his turn, and figuring with peculiar eclat in almost
every debated subject. In 1793, he was made a fellow of
Jeffery, Coll. of Honour and Benefactors; a set that in their
most glorious days did they speak better than they did
when young members of the Spectaculat. Already in these
 debates, Jeffrey, despite the Toryism of his father, was a
Whig at heart; he never consulted his father's wishes, while he
continued his habits of various thorough devoutly reading, and of incessant
composition in private on all sorts of subjects.
He had even a dream at this time that he was
born to be a poet; and he wrote, his biographer tells
of this great dream, says, from inspection, that though "viewed as mere literary practice
it is rather respectable," it could never have been accepted
as poetry. He adds that in one constitutional quality of the poet, Jeffrey was certainly highly endowed—the love of excitement. His work, according to Jeffrey, was in his earlier years, uniformly uphilt. It is significant of theperation of writing for the Edinburgh Review and political, to the purposes of rapid immediate effect, that, when a selection of his essays from the Edinburgh Review was published in four volumes in 1843, the work did not make much noise, and none of them were formally condemned, according to the similar collections of the essays of Macaulay, Sidney Smith, Carlyle, and others.

To return to Jeffrey's life, apart from the 'Review,' his professional practice rapidly increased, as his powers as a lawyer and orator were recognized; and it was found that he was not without a rival at the Scottish bar—combining good knowledge of law with singular perspicacity and ingenuity, and a rapid, fluent, and brilliant style of eloquence. He died, as a speaker in a libel case, where he was conducting the prosecution, after listening to his torrent of words, declared that, by calculation with his watch, 'that man had actually spoken the English language twice over in three hours.' Jeffrey's triumphs as a pleader in criminal and civil cases, were numerous; but nowhere was he more successful, or more in his element, than at the bar of the General Assembly of the Scottish Church, at its annual meetings in May, where he was usually retained in important ecclesiastical cases. With the increase of his practice there was a corresponding increase in his income. It is also of importance to note that he was a successful man professionally at Edinburgh, and Jeffrey were all afterwards the best of friends; and both the duel and the satire were laughed over among them. With Scott also, notwithstanding that their original political differences, were the cause of Jeffrey's resignation from the Edinburgh Review to aid in founding the Quarterly in 1809, Jeffrey always remained on terms of personal friendship; and nowhere were Scott's novels more cordially welcomed and praised than in the Edinburgh. At length, after remaining a widower eight years, Jeffrey married again. His second wife was an American lady, Miss Charlotte Wilkes, the daughter of Mr. Charles Wilkes of New York, and the grand-niece of Wilkes the notorious politician. He had met this lady during a visit of her family to Britain; but here they were parted for many years, until his return to America in 1813. During his brief stay in America, he saw some of the most important men in the United States, and formed an acquaintance with American society and literature, and with American literature. He had also been aided for some time in the new town of Edinburgh; but ultimately he removed to Craigcrook, a beautiful little property at the foot of the Corstorphine Hills, about two miles from Edinburgh, the old tarnished mansion of which, and the wooded grounds, were much improved by him in subsequent years. The vicinity of the place to Edinburgh made it perfectly convenient for his professional engagements; and till the time of his death he here received as his guests his professional and other friends, and all strangers of distinction who visited Edinburgh. The elegant hospitality of Craigcrook were proverbial; and the house and grounds retained their associations with Jeffrey, as Abbotford is associated with the name of Scott. Here Moore sang his songs under the roof of his former adversary, and here he remained till his death. Dickens formed that acquaintance with the venerable critic which ripened into so strong a friendship.

In the year 1821, Jeffrey was elected Lord Rector of the University of Glasgow. Whig politics were by this time in the ascendant in Scotland, and Jeffrey, as the Whig leader, took his part in the public meetings and other demonstrations which heralded the approach of the era of Reform. Having been chosen Dean of the Faculty of Advocates in 1829, he retired from the seat of his former rivalry, and here he remained till his death. The Edinburgh Review, which accordingly he resigned into the hands of Mr. Napier. He still took an interest in the Review, however, and at a considerably later period, when his son-in-law, Mr. Empson, succeeded Mr. Napier as editor, it was his delight to revise proofs and correct articles, as his son-in-law's deputy. In the meantime however he had passed
through new phases of his life. In 1830 he was elected a member of the first parliament of William IV., being returned for the borough of Douglas. In March 1831 he was unseated on petition, but was immediately returned again by Earl Fitzwilliam for the borough of Malton. He represented this borough till 1835, taking part in all the Reform debates; and in the end of that year he was returned for the borough of Edinburgh, along with Mr. Abercromby, the speaker (now Lord Donfermline). He remained in parliament till 1834, and was Lord Advocate of Scotland under the Grey government. His parliamentary speeches however did not attract much attention; it had been formed from his fame as a critic and a forensic orator; and he seems himself to have welcomed the change when, in 1834, he was raised to a vacant judgeship on the Scottish bench, and so relieved from the cares of political life. He had the reputation of an able judge, and hence Jeffrey was thereafter designated as Lord Jeffrey, though still legally only Francis Jeffrey, Esq. As a judge, he had a very high reputation for soundness, conscientiousness, and rapidity. He was noted for a habit of interrupting pleaders when they wandered, so as to bring them back to the point; and so long as he was in the second division more business was sent before him than before any other judge. He continued in the discharge of his duty almost to the last, dying at Edinburgh on the 27th of December 1850, he was buried at Craigcrook, on the 20th of January 1850. In the relotions of private life, Lord Jeffrey was a singularly affectionate and amiable man, soft-hearted to a degree which surprised those who, till they saw him, had figured him only as a sharp and severe critic. The best impression of this remarkable man is to be gathered from the selections from his correspondence published by his friend Lord Cockburn, as an appendix to his Biography, in 1852.

For his genius, the works of Professor J. S. Mill, belonging to the faculty of Logic and Ethics, established by Mr. Alder, and named after Mr. J. S. Mill, are to be referred to Rasselas. Forbes and Hanley give two species, J. d. sp. and J. d. sp., as inhabiting British seas.

...
JOHNSTON, JAMES F. W., late Professor of Chemistry in the University of Durham. He was born at Paisley, about the year 1796. His father subsequently moved to Manstone, Connecticut, afterwards returning again to England, and residing at Kilmarnock. During this time the education of young Johnston depended chiefly on his own efforts; he was however so successful that he was enabled to obtain his own livelihood by giving private instruction to pupils in the University of Glasgow. In 1835 he removed to Durham, where he opened a school. In 1830 he married the daughter of Thomas Ruddy, Esq., of Park-end. By this marriage his circumstances were so much improved that he gave up his scientific pursuits for a time, and remained as a farmer, long conceived of devoting himself to the study of chemistry. He accordingly repaired to Sweden, and became a pupil of the celebrated Berzelius. He made so much progress in his chemical studies, and became so well known as a chemist, that in 1846, Mr. Johnstone, the University of Durham, was invited to take the readership in chemistry and mineralogy. This took place in 1833, whilst he was yet pursuing his studies on the Continent, and the chair was not occupied till he returned to fill it. On his return, he took up his residence at Edinburgh, and devoting himself to the department of agricultural chemistry he became appointed chemist to the Agricultural Society of Scotland. On the dissolution of this society, he left Edinburgh, and resided permanently in Durham, where he devoted himself to the production of works on the relation of ch-short to agriculture. In this he was very successful, and few writers have been more extensively read in this department of literature. His Lectures on Agricultural Chemistry and Geology are an able exposition of the principles of chemical and geological science to the art of agriculture. He also published a 'Catechism' on the same subject, which at the time of his death, in 1855, had gone through thirty-three editions, and translated into almost every European language. He had travelled in America, and was well known as an agricultural chemist in the New World; and his works have there as large a circulation as in his own country. His experience of America he gave to the world in 'Narratives of Travels in North America,' in which he discusses many of the important agricultural questions connected with the resources of that great country. He was an eminent popular writer and teacher, and all his writings exhibit an enthusiasm which renders them attractive even to the unscientific reader. One of the most popular and the last of his works was his 'Chemistry of Common Life,' which has had a vast circulation, and done much for diffusing knowledge of the principles of chemistry involved in the ordinary occupations of human existence. A few years before his death he had written a 'Manual of Chemistry,' which was published in 1855. In the year 1843; in Travelling on the Continent in his natal health, when he was suddenly seized with spitting of blood, which terminated in a rapid decline, and he died at Durham on the 18th of December of that year. He was made a Fellow of the Royal Society in 1827, and was a member of other learned societies.

JOINT-STOCK COMPANIES. The great alteration in the principles which have influenced modern legislation with reference to Joint-Stock Companies calls for some repetition of what has been already stated with reference to them. [Bank, Banker, Banking Partnership] These Companies are distinguished from other Corporations by being associated, not for any public or administrative purposes, but for the purpose of carrying on a trade, with a view to individual profit. They possess other peculiarities equally deserving of notice. This system of association, which has received such gigantic development in the last century, was for a time widely known. and, of recent origin. Institutions founded on the same principle as the trading guilds of the middle ages seem to have existed among the Saxons; and soon after the conquest we find companies of different trades established in the various seaports and other towns of importance in the kils, or companies, other trading associations sprung up from time to time. The general company of Germans, called also the Merchants of the House, dates from 1290, and became in the fifteenth century the Company of the Steelyard. In 1658 the 'Merchants Adventurers' for the Company of the 'Merchants Adventurers to the Netherland,' obtained a charter of incorporation, prohibiting the former from interfering with them, and the Steelyard Company seems thereafter to have gradually declined. This Company established the merchants adventurers for the discovery of lands in America, the &c. &c., before known by the English, which resulted in the establishment of a trade with Russia. This Company subsequently obtained several Acts of Parliament, and still elects its officers. The Turkey Company, the African Company, the Eastland Company, the East India Company, were all chartered monopolies; but the Hudson's Bay Company alone remains on this ancient footing. Soon after the Revolution, the principle of association began to be applied to a variety of purposes besides those of foreign adventure. Numerous projects were started, the execution of which could not be compassed by private means, but which it was thought might be attained by raising capital on the joint-stock principle. Hence arose, in the early part of the eighteenth century, the speculative mania, remembered in connection with the famous South Sea Company; of which we have seen counterparts more than once in our own times. To meet the evils occasioned by this speculative mania, the 'Bubble Act' (6 Geo. 1, c. 18), was passed, declaring all companies which pretended to act as corporate bodies, and to pretend to raise transferable stock, public nuisances, and the promoters of them punishable accordingly. This statute, intended as a sop to quiet all who proposed schemes as a Corporation without authority, as with a view to prevent the frauds of unprincipled adventurers, who propounded schemes merely as basins to extract money out of the pockets of the thoughtless. Such an object, however, is not to be effected
by mere legislation. The gambling in stocks and shares which seems to be periodically revived among us, and which, in 1719, produced the 'Bubble Act,' came to an end during the crash following the wild speculation which led to the statute; but the Act, nevertheless, had some effect in restraining the desire of speculators for projects of the character to those against which its provisions were directed.

During the last century a large number of useful public undertakings, such as the making of canals, bridges, harbours, docks, and the like, have been carried into effect by companies. These joint-stock companies, which were first incorporated by Acts of Parliament; and more recently our gigantic system of intercommunication by railway has been obtained in a similar way. In these undertakings, the appearance of the joint-stock company was not so much to give a corporate existence to an association of capitalists, as to enable the company to carry out its project by the compulsory purchase of property, and to make by-laws binding on the public for protecting the rights of the corporation. These companies, like the old trading associations, partake of the advantages derived from incorporation; advantages in which mere associations of individuals joined together to promote such common objects cannot possibly participate. A mere assembly of adventurers cannot, for instance, by any agreement among themselves, or individually, give the name of any one of their body, or of any officer they may select for the purpose; they are liable, on the contrary, to the same laws as ordinary partnerships, and each individual is made liable for his own debts without limitation and omission of the contracts and debts, of the body generally. To facilitate the operations of such associations, various statutes have been passed; but owing to the fluctuation in opinion regarding the true policy to be pursued, the legislation relating to them has been rather confused.

The original mode of forming a joint-stock company was by means of a deed of settlement, which constituted trustees of the partnership property, directors of its affairs, and of its accounts, and other officers, defined the number of shares into which the capital was divided, and the form and mode of transferring them, and laid down rules for periodic meetings of the shareholders. In the absence of legislative interference, the rights and liabilities of the members of such bodies, in relation to the public, were the same as those of other members of ordinary partnerships; their rights and liabilities inter se depended on the provisions of the deed of settlement. The difficulties which were soon found to arise, in carrying on the business of such undertakings, induced the earlier joint-stock companies to obtain private Acts of Parliament, which usually enabled the company to sue and be sued in the name of the Secretary or some public officer appointed for the purpose, and almost invariably contained a clause whereby nothing could be done to incorporate the partnership; for one effect of incorporation would have been to destroy the individual responsibility of the members for the acts of the association, which the Legislature had, quite recently, most carefully retained. As joint-stock companies, however, in order to secure their usefulness, the cost and trouble necessary to obtain a private Act of Parliament were felt to be extremely burdensome; and the attention of Parliament being called to the subject, it was thought expedient by the Legislature to empower the Crown to grant to joint-stock companies such powers as were likely to be most useful to them, without, however, conferring all the incidents of a corporation. The first attempt at legislation in this direction was the statute 6 Geo. IV. c. 91, which enabled the Crown to incorporate them after to be granted, to provide that the members should be individually liable for the debts and engagements of the corporation. This Act proving ineffectual, another mode of proceeding was tried by 4 & 5 Will. IV. c. 94, which enabled the Crown to grant to joint-stock companies the privilege of suing and being sued in the name of any of their officers. This Act was soon repealed, and another attempt made in the same direction by 7 Will. IV. and 1 Vict. c. 72. The Act of 1840 was passed for the registration, incorporation, and regulation of all future joint-stock companies not requiring nor obtaining a charter or Act of Parliament. This statute introduced a system of public registration; and which the company became incorporated, for the purpose of carrying on banking or business for which it was formed, according to the provisions of its deed of settlement; but every shareholder remained liable individually for the debts and contracts of the company, and might be proceeded against as though he were not a member of the corporation. Banking companies were excepted from this statute, the 7 & 8 Vict. c. 113 being passed for their special regulation.

A great many joint-stock companies were formed, and by reason obtained the corporate privileges, which they were now enabled to do; but before long the affairs of several became involved; and the difficulties which thus presented themselves in attempting to adjust the rights and liabilities of the shareholders led to the Windig-up Act, 11 & 12 Vict. c. 45, and 12 & 13 Vict. c. 78, which several years exercised the acumen of the Judges of the Court of Chancery, in a series of hopeless attempts to interpret and follow out their provisions. The effect of the food of the Act was to give to the shareholders a very strong light upon the principles of legislation applicable to joint-stock companies; and the knowledge was purchased at an enormous expense, which has recently led to the repeal of the Registration and Windig-up Acts, and to a total remodelling of the law regarding these associations.

This has been effected by the statute 19 & 20 Vict. c. 47, which provides for the registration, under the provisions of these Acts, of all companies previously registered under the former statute. The Act itself has been amended by 26 & 27 Vict. c. 21.

The principle of limited liability, or the restriction of the responsibility of each member to the amount of the capital subscribed by him, which had long been conceded to partnerships, and corporations in the Staple, has been extended by the ordinary joint-stock companies. This statute contains a complete code for the effects to the commonwealth, has been at length extended to all joint-stock companies coming within the operation of these Acts, which choose to adopt their provisions, on the simple condition of obtaining registration and conforming to a few simple rules, whereby the personality of the companies is defined. From its operation are excepted all companies established by Act of Parliament, royal charter, or letters patent, all banking or insurance companies, and associations engaged in mining in the Stanniferous counties; companies with a limited liability may be formed conformably to certain local customs, which are generally known as the Cost-Book System.

There now exist, therefore, four classes of joint-stock companies.

1. Banking companies incorporated by special Acts of Parliament. This class includes railway, dock, harbour, and canal companies, many insurance companies, and a vast number of other bodies engaged in every species of profitable employment. Formerly each company thus incorporated was governed by the peculiar provisions of the Act which it obtained; but in order to introduce uniformity, a general Act, applying to all future companies, was passed under the title of 'The Companies' Clauses Consolidation Act,' 8 & 9 Vict. c. 25. This statute contains a complete code for the regulations of the proceedings, the transfer of the shares, and the general management of companies incorporated by Act of Parliament, 'The Lands' Clauses Consolidation Act,' 1840, was passed at the same time, consolidating all those provisions of earlier acts, and defines the special Act of any company, which required powers of acquiring land compulsorily for the purposes of the undertaking.

The peculiar character of railway undertakings rendered necessary 'The Railways' Clauses Consolidation Act,' 1845; which lays down regulations as to the construction of railway works, the amount and mode of enforcing the payment of tolls and fares, and the making of by-laws for the conduct of their business, which are binding upon all persons whatsoever.

2. A second class of joint-stock companies are the very few established under the statute 1 Vict. c. 73, or the proceeding Act, 6 Geo. IV. c. 91, which have been already referred to.

3. Banking companies formed since 1844 form a distinct class. They were until recently regulated by the statute 7 & 8 Vict. c. 113, but must now be registered under 'The Joint Stock Companies' Act, 1846.' This Act was nearly intended to limit the individual liability of the partners, and contains provisions for the company being wound up. Banking companies constituted previous to 1844, may avail themselves of the advantages of the statute, by being registered under its provisions.

4. The last class of trading corporations are the registered joint-stock companies, regulated by 'The Joint-Stock Companies' Acts, 1850 and 1867, under which seven or more
persons may, by subscribing a memorandum of association, and otherwise complying with the requisitions of the statute in respect of registration, form themselves into an incorporated company, with or without limited liability.

This registration is conditioned upon the subscriber or subscribers, or the registrar of joint-stock companies a memorandum of association, stating certain particulars in a prescribed form. Upon registration being effected, the subscribers, together with any person as from time to time shall by agreement of the company, become a body corporate, having a perpetual succession and a common seal, and power to hold lands to a certain extent, and with consent of the Board of Trade to any extent whatever.

The company hold itself forth to the public as one of those which the members are liable either with or without limit, according as the founders of it choose to adopt the principle of limited liability or not. Where the liability of the shareholders is limited, it is by the memorandum of association, the word 'limited' must be the last in the registered title of the company, and must be inseparably attached to its name.

The statute requires that a register of shareholders shall be kept; and that this list be annually revised, and a copy furnished to the registered joint-stock companies. This copy is open to public inspection, so that all the particulars of importance respecting the company can be at any time ascertained by persons dealing with it.

The affairs of a registered company are also liable to examination, and the Registrar of Companies is empowered to demand, and from time to time to examine into the accounts, and to make an inspection of the properties of the company, to see if the same are being properly managed, and if the company is being conducted according to its memorandum of association or the conditions in which it is or has been registered.

Any person is authorized to demand of the Registrar an order to inspect the books, accounts, and documents of any company, and the Registrar is bound to issue such an order on any application of a creditor, subscriber, or the like, provided he is satisfied that the same are not being properly managed, or are not being conducted according to the conditions in which the company is registered, or are not being conducted according to the conditions in which the company is registered.

The insolvency of the company is necessary to the dissolution of the company. The patent or deed of incorporation of the company must be surrendered to the registrar of companies, or to the court of probate, or to the court of exchequer, or to the court of chancery, as the case may be, whenever the company is dissolved.

The dissolution of the company is in all cases declared by the court of probate, the court of chancery, the court of exchequer, or the court of admiralty, according to the circumstances of the case. The court of probate is the court of first instance, and the court of chancery is the court of appeal, and the court of admiralty is the court of appeal in admiralty.

This species of company may be dissolved by being wound up, either voluntarily or compulsorily. A voluntary winding up may take place: 1. Whenever the period, if any, fixed for the duration of the company expires, or the event or accidents, on which it is to be dissolved; 2. Whenever the company has passed a special resolution requiring its winding up.

A company may be wound up compulsorily: 1. By virtue of a special resolution to that effect; 2. Whenever it does not commence business within a year after its incorporation, or suspends business for a year; 3. Whenever the shareholders are less than in number: 4. Whenever the company is unable to pay its debts: or, 5. Whenever three fourths of the capital have been lost or become unserviceable.

A company is to be deemed unable to pay its debts: 1. Whenever a creditor for 50l. has served a demand of payment, and the company has for three weeks neglected to pay or arrange or settle the claim; 2. Whenever the satisfaction of the creditor: and, 2. Whenever an execution is returned unsatisfied, in whole or in part.

The proceedings take place in the case of companies whose liability is unlimited, in the Court of Chancery; in the case of companies with limited liability in the Court of Bankruptcy. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. i. p. 363.)

JOSEPH-ETTIENNE DE, was born in the hamlet of Jouy, near Versailles, in 1760. When only thirteen he accompanied the governor of French Guyana as sous-lieutenant to that colony, but remained there scarcely a year. He returned to Versailles, continued his education for two years, and then left France a second time for the French East Indian possessions as an officer in the Luxembourg regiment. In 1790 he was again in France, joined the revolutionary party, and rapidly attained military promotion, but during the war of the French Revolutionary Wars, which he spent in the Swiss canton of Schwyz. On Robespierre's fall in July 1794 he returned to Paris, was placed on the staff of the army of Paris under General Menou, and contributed to the triumph of the Convention in the streets of that city on the 21st of May (2nd French Consul) with the Second Battle of Paris, on the 5th of June, then released, and sent as commander to Lille; then again arrested on an accusation of being in communication with Lord Malmesbury the English minister, but acquitted and restored to his functions. Disgusted however with these repeated prosecutions he resolved to abandon his military career; he therefore solicited his discharge, which he obtained together with a pension for his good services and wounds. He was now thirty years old, and after a few months' service in the fleet of M. de La Veriere, and in 1797, was transferred to the 3rd Dragoons, in which gained him admission to the Academy in 1815. This was followed by several other operas, among which were 'Les Amazones,' with music by Meyeh, and 'Les Absences,' with music by Cherubini, which still retain possession of the stage. He has also written 'Sylva,' a comic opera, the reverse, with considerable success; and several tragedies, of which 'Syella' obtained a marked success. The work however on which his reputation mainly rests is 'L'Hermitte de la Chaussée d'Antin,' a series of essays on men and manners in France, which first appeared in the 'Gazette de France,' in 1813-14, and were afterwards collected and published in five volumes, 12mo, 1815. They were considered in France as the successful rivals of the English 'Spectators,' 'Guardsmen,' and 'Rambler,' though they doubt have considerable merit, the style is easy, the observation acute, the description animated, and the characters often drawn with much quiet humor. They may exhibit some resemblance to the essays of Addison or Steele, but none whatever to those of Johnson. They display a happy mingling of the serious and the comic, but they have little depth. Some attempts are made at the pathetic, but they are rather mandlin. They were however very successful in France, and the author followed up his success by the 'France Parlez,' 'L'Hermitte de la Guyane,' 'L'Hermitte de la Martinique,' series of novels, the last a collection by several writers, but all infinitely inferior to the first. 'L'Hermites en Prison,' however, and 'L'Hermites en Liberté,' written in 1823 and 1824, in conjunction with M. Jay, were of a better kind, and henceforth published under the patronage of the liberal party in France. M. Jouy has also written on political economy, and likewise two novels, 'Colli,' and 'Le Centenaire,' in 1827 and 1833. He edited for some time the 'Journal des Arts,' and he contributed innumerable articles to various newspapers and journals. He died at Paris in October 1846.

JUDICIAL COMMITTEE. The appellate jurisdiction of the Judicial Committee of the Privy Council has been already mentioned [Delattre, 'Court or, &c.'], It only extends to cases in which the courts of England, Ireland, and Scotland, or the courts of admiralty, and colonial causes, the Judicial Committee has been recently constituted the Court of Appeal from the judgments of the Court of Probate. It also decides upon applications for the admission of aliens to the patent books of the state, and the republication of books, which, after the death of the author, the proprietor of the copyright has refused to publish.

JUDICIAL SEPARATION. [Separation, Judicial, &c.]

JUDSON, ADONIRAM, founder of the American Baptist Mission in Birma, was born August 9, 1788, at Malden, Massachusetts, where his father was a Congregationalist minister. Having passed through the classes of Brown University, where he took honours, he entered the Andover Theological Seminary, and then, a year before, a sermon by Dr. Claudius Buchanan, which he chanced to meet with, turned his thoughts towards the missionary service in India. Some fellow-students, to whom he communicated his views, became similarly interested, and they eventually persuaded the college authorities their desire to devote themselves to the missionary office. There was then no missionary society in America, but the council referred the matter to a general committee, who resolved that it was advisable to institute a 'Board of Commissioners, with a view to the promotion and the republication of books, which, after the death of the author, the proprietor of the copyright has refused to publish.'

JUDSON, ADONIRAM, founder of the American Baptist Mission in Birma, was born August 9, 1788, at Malden, Massachusetts, where his father was a Congregationalist minister. Some fellow-students, to whom he communicated his views, became similarly interested, and they eventually persuaded the college authorities their desire to devote themselves to the missionary office. There was then no missionary society in America, but the council referred the matter to a general committee, who resolved that it was advisable to institute a 'Board of Commissioners, with a view to the promotion and the republication of books, which, after the death of the author, the proprietor of the copyright has refused to publish.'

Having on the 5th of February 1812 married Miss A. Hasseltine, he, twelve years after, embarked with his young wife for India. Four months later they landed at Calcutta,
where they met with a warm welcome from Dr. Carey and his wife. The next day the government, unaccustomed to having the blessing of a remunerated home missionary, ordered Judson and his companions to return to America by the same ship in which they had arrived. Judson had been appointed for a missionary work, and he was henceforth to be considered as such. He accordingly started on the 14th of April, 1813, and returned, as is recorded, to Rangoon, in Burma, where he arrived July 14, 1813.

Before leaving Calcutta, Mr. Judson, whose views on the subject of baptism had undergone a change, was, with his wife, re-baptised by immersion by Dr. Carey. In consequence of this change of opinion with regard to baptism, and when he returned to Rangoon to commence his missionary work he was unconnected with any society, and without any means of future support. He addressed himself however with success to some of the chief people of the country unaided by dictionary or grammar, whilst the native he engaged as a teacher knew not a word of English. By persevering labour he in some two or three years was able to speak the language with some degree of readiness. The Baptists of America, on hearing of his devotions, had promptly formed a missionary society to support him, and sent him some assistance, one of whom was a printer. The Samaritan missionaries presented a printing-press and a font of Birmese type. Mr. Judson, now not only engaged in preaching and teaching, but also in writing and translating, laboured to benefit those whom his voice could not reach, drew up in Birmese a 'Summary of Christian Doctrine,' which was the first work issued from the Rangoon press; and portions of scripture and sermons were translated as speedily as possible. As the mission was fairly at work Mr. Judson made visits to other Birmese towns, and to Ava, where he had an interview with the king; and, having obtained permission set about establishing schools, in which Mrs. Judson, who had also mastered the language, was a very great help. The mission was so successful that help was required from the British camp to mediate. A treaty of peace being signed, Mr. Judson and his companions were permitted to resume their labours. He returned to Rangoon; and, there, worn out with toil and anxiety, the companion of his early dangers and the sharer of his labours died, October 25, 1815, leaving his absence felt in Ava. Some eight years later he married a second wife, the widow of a fellow-missionary named Boardman.

From an early period Mr. Judson had regarded the translation of the Scriptures into Birmese as a work of the first importance in his life; and, after having been for several years engaged upon it, he at length, January 31st, 1834, had the happiness to complete his task. He lost no time in putting it to press; and, by the end of 1835, the printing was finished of the first edition, in 3 vols. laege 18vo. Each volume was divided into many sections, and the writings of the many imperfections, and he at once set about thoroughly revising the whole, with such assistance as he could obtain. This revision was completed in the autumn of 1840, and immediately printed in a thick 4to volume. It has since undergone careful correction by various Oriental scholars, and now holds a high place among the translations of the Scriptures into the eastern tongue. Almost as soon as the printing of this revised edition of the Bible was finished, with characteristic energy, Mr. Judson was engaged at Moulmein in the work of his country, and the mission was removed, the preparation of a Birmese Dictionary. But his own ill-health interrupted the work, and the health of his wife failing also, he determined to return to America, in the hope that their native air might restore their vigour. Mr. Judson died off St. Helena (September 27, 1852) while on his journey. He arrived in safety at Boston a month afterwards. His reception by the various religious societies in America was one of the most enthusiastic kind. Special services were everywhere got up in his honour; and the marriage of his second wife (a memoir of the first had already been written), was expressly arranged to accommodate young lady, Miss Chubbuck, whose writings under the pseudonym of Fanny Forrester, had had an unusually large amount of popularity in religious circles; and she was invited to attend the funeral of the life of the · very Worms, the dying Mrs. Judson, but soon consented to become the third. They were married in June, 1846; and in July they embarked at Boston, and in December they landed at Moulmein. The mission was now in a flourishing state, and Judson felt that he might now devote himself to the completion of his Dictionary. Of this he was permitted to see the first part printed in 1849, but he did not live to complete it. His health failed, and he was directed to proceed to the Isle of Bourbon to recruit his forces. But, growing worse, he was allowed to return to the 12th of April, 1852. His 'Birmese and English Dictionary' was completed from his papers by Mr. E. A. Stawens, and printed at Moulmein in 1852. It is regarded as a work of great value, and is a fact that it was written in a language spoken by more than a million people. His 'Birmese and English Dictionary' was completed from his papers by Mr. E. A. Stawens, and printed at Moulmein in 1852. It is regarded as a work of great value, and is a fact that it was written in a language spoken by more than a million people.
struggle with in devoting himself to his favourite pursuits. His example appears to have produced an effect on others of the family, for Antonin, a younger brother, became a physician, and entered the military service, and was eventually transferred to the schools of Bohemia in 1774, and Jungmann, though from his name he was evidently of German descent, and though, as his after life evinced, he had talents for acquiring languages, seems to have left his peculiar bardine the Bohemian language. He was still more distinguished by his celebrated attainments in the Bohemian language. He made it the main business of his after life to restore and promote the study and cultivation of the Bohemian language, which, in his boyhood, was almost abandoned to the use of the peasantry, and which, owing to its being treated as a secondary language of Bohemian authors, who were formerly accustomed to employ either German or Latin. He studied first at Beran, and then at the University of Prague; and in the year 1799 obtained an appointment as teacher in a Bohemian grammar school, of Leitmeritz, where he devoted part of his leisure to giving gratuitous instruction in Bohemian. While at Leitmeritz he translated several specimens of English poetry— Pope's "Eloisa," and "Messiah," and Dr. Johnson's "Edwin and Angelina;" Gray's "Elegy in a Country Churchyard;" and above all the "Paradise Lost," which was completed about 1804, but not published till 1811, and which came to a second edition in 1843, in the "Novocek's Bibliothek," where it was transferred to Prague as professor of Latin at the grammar school of the Old-Town, of which, in 1834, he became the prefect, or principal. In 1840 he was chosen rector of the university, an office which was delivered to him by his brother Jan. In 1842 he was transferred to a more important post, when his brother Jan had assumed the management of the gymnium, but he was still occupied with correcting works for the press at the time of his death, on the 18th of November 1847. He had for several years been an asylum, or in the native tongue. In 1845 the infancy of age compelled Josef to retire from the management of the gymnium, but he was still occupied with correcting works for the press at the time of his death, on the 18th of November 1847. He had for several years been and the ordinance of the Ministry of Education, and besides being decorated with the grand eagle of the Legion of Honour. He was likewise sent on several missions to the Court of Lisbon, his part of ambassador being suddenly changed at last into that of aggressor, when the good understanding between France and Portugal had ceased, in 1806. Junot then took forcible possession of Portugal, and held his ground there for nearly two years, when Sir Arthur Wellesley's victory at Vimiera, on the 21st of August 1808, and the evacuation of the city of Lisbon, brought an end to the occupation of Portugal by the French army, and Junot's return to Paris. He had already received his title as Duc d'Abrantes; but from this period he lost all favour with Napoleon, having no chief command to gratify his ambition. In 1812, the title of the Grand Army was assumed by the viceroy, and the 6th corps was ostensibly placed under his command, but the orders from Berthier were rather to his lieutenants than to himself, and the only time his name was mentioned in a bulletin, he was reflected upon as having shown "a want of resolution." Under this reproach his spirit sank; he was refused employment in the campaign of 1813, and shortly afterwards was attacked with mental disease. In this state he was conveyed to the house of his father, at Buzenans, on the 22nd of February 1816; the following day he threw himself out of a window, broke one of his thighs, and it became necessary to amputate the leg. He died on the 29th.

Laura Praxedis, Duchess d'Abrantes, was born at Montreal, November 6, 1784, and was only sixteen when married to Junot, in 1800. She was a woman of great frankness of speech, and equally remarkable for the propriety of her expenditure. As a consequence she made enemies at court, and during her husband's absence from France she obtained an annuity of 12,000 francs, which she was to use for the benefit of the poor. In 1811, Napoleon had turned the tide of his fortune, she had no savings to support herself and family. She therefore had recourse to her pen for her subsistence. She wrote many tales and novels, but her principal work was her Memoirs, which were written between 1798 and 1813. As these memoirs contained many incidents relating to the early life of the French emperor, its success was universal throughout Europe. The Duchesse d'Abrantes died in extreme poverty on the 27th of June 1839.
K

KAFFRARIA. [AFFRARIA]
KAFFRARIA, BRITISH. This name is applied to a dependency or military possession, recently annexed to the Cape Colony in South Africa. The annexation arose out of the Kaffir War of 1847. For twenty years before that date the settlers in the Albany district of the Cape Colony, being near the eastern frontier, were often exposed to invasions from the Kaffirs. Successive governors of the colony—Sir B. D'Urban, Sir P. Maitland, and Sir H. Pettinger—had endeavoured in vain to suppress these inroads. In 1847 Sir H. Pettinger sent a force to attack the Kaffirs himself; but his endeavours were successful only temporarily; the Kaffirs continued to be seated against the white settlers or lack out again with great force in 1850. On the last day of that year Sir H. Smith issued a proclamation from King William's Town establishing military law in the colony, and ordering all colonists between the ages of 16 and 20 to rise en masse to defend the frontier against the Kaffirs. The British troops suffered much annoyance and loss in the harassing bush-warfare which ensued. On the 8th November, 1851, in an encounter with the Kaffirs in the Waterloof, Lieutenant Colonel Fordyce and several officers and men of the 74th regiment were killed, and a considerable number wounded; the Kaffirs escaping unhurt. In January 1852 Major General Cathcart replaced Sir H. Smith. On the 20th December General Cathcart defeated the Basutos, a Kaffir tribe, on Berea Mountain in the Orange Sovereignty, shortly after which three chiefs named Macomo, Sandilli, and Krell submitted to the British, and the war was virtually at an end. A treaty of peace was ratified at a conference between the British and the Basutos held near King William's Town on the 9th of March, 1853. This war cost England about a million and a half sterling. The country called British Kaffraria is a large district eastward of Cape Colony, on the eastern side of the Orange river. It is a kind of sovereignty or protectorship, the precise character of which has not been very clearly defined. British military posts are maintained at various points over the area. The district is divided into counties. Buffalo River is considered the harbour. A town called Basuto was established at the mouth of Buffalo River.

KALE, or KAIL, SEA. [CHAMBA.]
KAI SARIEH, a town in Asia Minor, is situated in a plain to the north of the Euphrates (the ancient Argoans) in about 36° 41' N. lat., 35° 25' E. long., and has a population variously estimated at 28,000, 40,000, and 50,000, consisting of Turks, Greeks, and Armenians. The plain is laid out in corn-fields, and screened on the east and west by low hills covered with gardens and vineyards, and the whole neighbourhood abounds with volcanic deposits. The town is surrounded by an old walled moat, and further defended by an old citadel partly in ruins. The houses, which are from 8000 to 10,000 in number, are built of stone and lime, but many of them have a cracked and dilapidated appearance caused by the frequent earthquakes. The streets are narrow and dirty, the squares and market-places also abound with filth; and the naturally healthy climate is poisoned by the filth. Among the principal manufactures of this town are leather, wine, and tobacco. The chief exports are corn, beans, rice, and tobacco. The Armenians have a bishop and two churches in Kaisarieh; the Greeks also have a church. The manufactured products of the town are chiefly yellow marocco leather, cotton stuff, and cotton-yarn.

Kaisarieh in site and sound is identical with the ancient Cesarea, the capital of Cappadocia, which was originally called Mazaca. The plain in which it stands is watered by the Melas, now called the Karasu, which was dammed up by King Ariarathes to form a lake a little above its entrance into the Halys (not Enaphrates as erroneously stated by Strabo). Mazaca was called also Beroeia, and numerous coins with this epigraph have been found on the site. It was taken by Tigranes, and its inhabitants carried off to his new capital Tigranocerta. When Cappadocia was made a Roman province in the reign of the emperor Tiberius, Mazaca was named Cesarea. It became a place of great importance in the later times of the empire. When taken by Sapor in the reign of Valerian (a.d. 259) it had a population of 400,000. In the reign of Justinian the walls were repaired. There are many ruins and heaps of rubbish of ancient structures about the town. Cesarea gave title to a Christian bishop from an early period of the Church; it is the bishop's place of St. Basil the Great, who became bishop of Cesarea, a.d. 370.
KANE, ELISHA KENT, M.D., of the United States Navy, was born February 2, 1830, in the city of Philadelphia. He was a son of Judge Kane, of Philadelphia, and the elder brother of Dr. James S. Kane, of the University of Virginia, and studied medicine in the University of Pennsylvania, where he graduated with honours as M.D. in 1842. He was almost immediately afterwards appointed Secretary to Sir George Cockburn, the governor of New South Wales, and settled on the interior of the island of Ceylon, and availed himself of the facilities afforded by his position to explore the Philippines, which he accomplished chiefly on foot, and made charts and maps which are still preserved. He descended into the great crater of Tael, in the island of Luzon. The descent had only once before been attempted by a European, and was unsuccessful. Dr. Kane was lowered into the crater by means of a rope formed of bamboo, and reached ground at a depth of more than 200 feet. He then obtained for himself from the rope, and clambering downwards dipped his specimen-bottles into the smoking lake. In returning, the hot ashes charred his boots; and owing to their giving way under his feet, he fell repeatedly before he was able to get up. His position in the Melinead crater, which was at length hauled up nearly insensible. After remaining some time in China, he traversed a part of Hindostan. He afterwards proceeded to Egypt, where he examined the interesting antiquities of the Upper Nile, but unfortunately lost his life in a journey to the Red Sea, while in the Melinead crater, and was at length hauled up nearly insensible. After being wounded in the battle of Napolocca. Dr. Kane was engaged in the American coast-survey of the Gulf of Mexico, when he received a notice by telegraph, May 12, 1850, of the intended expedition in search of Sir John Franklin, by means of two vessels furnished by Mr. Grinnell of New York, and fitted out at the expense of the government of the United States. He immediately hastened to New York, and on the 22d of May the two vessels, the Jason and the Sarah, were launched, and fitted out by the city. Dr. Kane was attached to the expedition as senior medical officer, on board the Advance, under Commander De Haven. The expedition left Baffin's Bay, its return, September 6, 1851, and after a favourable passage of twenty-four days, they reached the mouth of the Expedition Channel. The U. S. Grinnell Expedition in search of Sir John Franklin, a Personal Narrative by Eliza Kent Kane, M.D., U. S. N., with Illustrations, 8vo, 1853, London and New York. Before he had completed the preparation of this work for the press, Mr. Grinnell of New York, in conjunction with Mr. Peabody of London, prepared a second searching expedition, in the Advance, which was placed under the command of Dr. Kane, and sailed from New York on the 31st of May, 1853. The Advance sailed from Baffin's Bay, and through Smith's Strait, and reached 70° 43' N. lat., the highest latitude attained by any of the expeditions, except that of Parry in his attempt to reach the North Pole. The Advance was frozen up during twenty-one months, provisions became scarce, and the supplies were at length exhausted, the men were affected with scurvy and other sickness, and two of them died, as did also the sledge-dogs. Dr. Kane, under these circumstances, resolved to quit the ship, and endeavour, partly in boats and partly in sledges, to reach the coast. He left Greenland, 3,130 miles south from the position of the Advance. During the greater part of this journey their daily provision consisted of six ounces of bread-dust and a piece of frozen tallow the size of a wax candle. A great many, it is supposed, perished, and when almost in a state of starvation, they killed a seal. At the end of eighty-four days they reached the Danish settlements of Upernavik, where they were kindly received and hospitably treated. Only one man was lost on this terrible journey, and he by accident. Meanwhile, nothing having been heard of Dr. Kane and his party, the government of the United States fitted out a relief-expedition, consisting of a small screw-steamer and a clipper-boat, under the command of Lieutenant Harlow of the United States navy. This expedition sailed from New York on the 31st of May, 1855, and, having reached the Danish settlements, the missing party were found, and arrived at New York on Oct. 11, 1855. In May, 1856, the gold medal of the Royal Geographical Society of London was awarded for their signal services and important discoveries in the polar regions, and for his valuable memoir and charts. In 1856 Dr. Kane published his 'Arctic Explorations: the Second Grinnell Expedition, 1850-51,' Philadelphia, 8 vols. 8vo. In the autumn of the same year he paid a visit to England, and being in a state of failing health proceeded thence to the island of Cuba, in hope that he might derive benefit from the climate, but died at Havana, February 16, 1857. His remains were consigned to his native city of Philadelphia, and were interred there with unusual demonstrations of public respect and grief.

A badly written 'Biography of E. K. Kane,' by W. Elder, was published in 1858.

KANSAS, a Territory of the United States of North America, established by Act of Congress 1854, occupies the country lying along the river Kansas, north of the Indian Territory, and extending northward to the Nebraska River. It is bounded on the north by the Great Lakes, on the west by the States of Iowa and Missouri; S. by the Indian Territory; W. by the Rocky Mountains, and N. by the Territory of Nebraska. The area is 114,706 square miles. The estimated population in 1856 was 34,000.

By far the greater portion of the territory consists of an unreclaimed wilderness, over which roam tribes of native Indians in search of game. The eastern and southern portions are broad open prairies, well watered and very fertile, but thinly inhabited. The western portion of the Territory forms a part of the Great American Desert, which is said to be for the most part wholly irreclaimable, and to present scarcely an oasis. On the west are outlying members of the Rocky Mountains. The chief river of the Territory is the Kansas, which rises on the northern side of the territory, and joins the Rocky Mountains, between the sources of the Arkansas and Nebraska. Its two principal branches, the Republican and Smoky Hill forks, run for a considerable portion of their course at a distance of 150 miles apart. Republican Fork issues from a rather large lake between 30° 32' N. lat., 103° 30' W. long.; Smoky Hill Fork rises in the mountain region east of South Peak: their junction is near 39° N. lat., 100° 30' W. long. The united stream is known as the Kansas: it is navigable for a great part of its course. Its general course is to the south-east, and joins the Missouri in 38° 50' N. lat., 94° 28' W. long. It has a full body of water, is 340 yards wide at its mouth, and is said to be navigable for steam-boats for 150 miles, and for keel-boats, with its forks, for some hundreds miles higher. Republican Fork, the larger of the two, is used extensively by the Missouri, and receives on its right side two considerable affluents, Solomon's Fork and the Grand Saline. Numerous smaller tributaries swell the main stream and its affluents. The chief of the secondary streams belonging to this Territory, which fall into the Missouri are the Nemawhaw and the Independence. The Missouri itself forms the eastern boundary of Kansas, and affords an invaluable outlet for its products. The Nebraska River, on the northern side of the Territory, is a very wide but shallow river, with a rapid current and a bed of shifting sand-banks; it is navigable by steam-boats for about 50 miles. The great emigrant and freemont routes to Oregon, Utah, and California lie across the Territory of Kansas, and follow the line of one or other of these rivers.

As far as the country has yet been examined geologically, its southern and eastern parts appear to belong to the Lower Carboniferous system; the rocks consisting largely of mountain limestones and sandstones. In the south-eastern corner is a very wide but shallow river, with a rapid current and a bed of shifting sand-banks; it is navigable by steam-boats for about 50 miles. The great emigrant and freemont routes to Oregon, Utah, and California lie across the Territory of Kansas, and follow the line of one or other of these rivers.

The river bottoms have a rich alluvial soil. The few settlers who have established themselves within the Territory are said to report very highly of its capabilities, but as yet even
The surface of the country is very little known. The only settlement beyond the recently-founded city of Worcester and a few scattered farm-houses, is the military station of Fort Laramie in Wyoming.

The vast tract known as Nebraska, including an area of upwards of 306,000 square miles, of which Kansas forms the southern part, was a portion of the country purchased by the United States from the French in 1803. It has been left till recent times under Indian dominion, the constant stream of western migration, which caused the growth of one and another Territory and State on its eastern and southern borders, and still more recently the blow struck by the Kansas and Nebraska Railroad across the territory between Utah and California, led to propositions which increased yearly in urgency for its organisation as a Territory. The first bill for the organisation of the Territory of Nebraska was introduced into Congress in 1846, but rejected. Subsequently a second bill was introduced in 1847, and a third session of 1854 a bill was introduced for forming out of this extensive tract two Territories, Nebraska in the north, and Kansas in the south; and as the form of the bill re-opened the question of the admission into the Union of the new slave states north of 36° 30' N. lat., which the measure known as the Missouri Compromise was understood to have settled should not be done, it was made the occasion of a most earnest struggle between the supporters and opponents of slavery. The bill was passed, and the new Territories of Nebraska and Kansas were formed by an act of Congress on May 30, 1854, which was introduced by the late H. C. P. Bingham, of Ohio.

In preparing this map a careful examination of the reports on the territory and documents in the hands of the Department of the Interior, and of the records of the United States, have been consulted. The boundaries are taken from the maps of the United States in the possession of the Bureau of Education, and the chief objects of interest have been marked. The railroads are those which are in existence or proposed for construction.

Utah Territory.

The KANURAN, or KARAN, has been sometimes given also to the Persian province of Kerman. [Persian.]

KARIA, or KARINA, a division of Asia Minor, which comprised the south-western corner of that peninsula. It was bounded S. and W. by the Mediterranean Sea, N. by the valley of the W. branch of the Taurus, E. by the Caspian Sea, and S. by the Persian Gulf, and is bounded by the Euphrates, which is omitted on the map. Kerman was the seat of a flourishing petty sovereignty in the 14th and 15th centuries. It is identified with the ancient Laranda.

The name Karamania has been sometimes given also to the Persian province of Kerman. [Persian.]
It is identified by the Ionian revolt (a.d. 499-494) the Carians fought bravely side by side with the Greeks, but were at last compelled to submit. Under the protection of Persia, Caria was ruled by a dynasty of princes, whose capital was Halicarnassus. Aristeas, who was called son of Xerxes by some, and brother by others, was the king of Halicarnassus. This city was the seat of a queen, called Ada. She surrendered to Alexander the strong city of Alinda, in consideration for which he restored her to the royal authority of which she had been deprived. Caria afterwards became successively subject to the Greek kings of Asia, and was eventually in the hands of the Romans. Thus Caria, which in the times of Herodotus was one of the seven petty sovereigns, became afterwards the birthplace of Herodotus and Dionysius the historians. It was founded by a colony from Troizenias Argolis, was the largest and strongest city in all Caria, and became the seat of a Carian dynasty under the protection of Persia. Caria contained two towns, Halicarnassus, erected in his honor, the celebrated sepulchral monument called the Mausoleum, of which there are still remains as well as of the ancient walls. Some interesting sculptures, supposed to have formed part of the decoration of the Mausoleum, are now in the British Museum. Halicarnassus was destroyed by Alexander the Great. The Carian was a warrior, not addicted to commerce like the Greeks; their prosperity was that they hired themselves as mercenaries, and served under the kings of Egypt.

Among the towns of Caria were Caria (the Ionian revolt) and Halicarnassus, which were the names of the Doric cities in Asia. Halicarnassus, the capital of Caria, and Delos, were the seats of the Carian king, and the birthplace of Herodotus. The Carian capital, the site of Caria, was called Caria, and stood near the Gulf of Caria. Herodotus, in his account of the Ionian revolt, says (p. 499-494) the Carions fought bravely side by side with the Greeks, but were at last compelled to submit. Under the protection of Persia, Caria was ruled by a dynasty of princes, whose capital was Halicarnassus. Aristeas, who was called son of Xerxes by some, and brother by others, was the king of Halicarnassus. This city was the seat of a queen, called Ada. She surrendered to Alexander the strong city of Alinda, in consideration for which he restored her to the royal authority of which she had been deprived. Caria afterwards became successively subject to the Greek kings of Asia, and was eventually in the hands of the Romans. Thus Caria, which in the times of Herodotus was one of the seven petty sovereigns, became afterwards the birthplace of Herodotus and Dionysius the historians. It was founded by a colony from Troizenias Argolis, was the largest and strongest city in all Caria, and became the seat of a Carian dynasty under the protection of Persia. Caria contains two towns, Halicarnassus, erected in his honor, the celebrated sepulchral monument called the Mausoleum, of which there are still remains as well as of the ancient walls. Some interesting sculptures, supposed to have formed part of the decoration of the Mausoleum, are now in the British Museum. Halicarnassus was destroyed by Alexander the Great. The Carian was a warrior, not addicted to commerce like the Greeks; their prosperity was that they hired themselves as mercenaries, and served under the kings of Egypt.

Among the towns of Caria were Alabanda, which was the name of the Doric city in Asia. Alabanda, the capital of Caria, was called Caria, and stood near the Gulf of Caria. Herodotus, in his account of the Ionian revolt, says (p. 499-494) the Carions fought bravely side by side with the Greeks, but were at last compelled to submit. Under the protection of Persia, Caria was ruled by a dynasty of princes, whose capital was Halicarnassus. Aristeas, who was called son of Xerxes by some, and brother by others, was the king of Halicarnassus. This city was the seat of a queen, called Ada. She surrendered to Alexander the strong city of Alinda, in consideration for which he restored her to the royal authority of which she had been deprived. Caria afterwards became successively subject to the Greek kings of Asia, and was eventually in the hands of the Romans. Thus Caria, which in the times of Herodotus was one of the seven petty sovereigns, became afterwards the birthplace of Herodotus and Dionysius the historians. It was founded by a colony from Troizenias Argolis, was the largest and strongest city in all Caria, and became the seat of a Carian dynasty under the protection of Persia. Caria contains two towns, Halicarnassus, erected in his honor, the celebrated sepulchral monument called the Mausoleum, of which there are still remains as well as of the ancient walls. Some interesting sculptures, supposed to have formed part of the decoration of the Mausoleum, are now in the British Museum. Halicarnassus was destroyed by Alexander the Great. The Carian was a warrior, not addicted to commerce like the Greeks; their prosperity was that they hired themselves as mercenaries, and served under the kings of Egypt.
tiful Ionic temple of Aphrodite, from whom the town was named. There was a city Planae, probably not far from Aphrodisias. Fellows ("Asia Minor") says that Obura is the exact place. In 1856 the town was entirely destroyed by Mount Cadmus, near the confines of Caria, Lydia, and Phrygia. It was famous for its hot springs on the banks of the Meander, by which its site has been identified. Hamilton ("Researches") conjectures that the town was named from its position on the boundary of Caria towards Phrygia (Καρπος).

North of the Meander were Tripolis, near the point where the river enter the plains (38°'1 N. lat.), where are ruins of ancient theatres and temples, and some on by Lysippe, Ma-taura, west of Tripolis and north-east of the modern Nazeli, and near the modern village of Manastian, has some ancient ruins, most of which are overgrown with underwood, and a fine spring of cold water: Trullus, situated on a picturesque hill, was at one time inhabited by the Galatae, a tribe generally located to Lydias, to which later times they seem to have belonged.

Along the west coast beyond Halicarnassus were Myndus, once the capital of Caria: Caryanda, a city which seems to have been partly on an island and partly on the mainland, two parts separated by a narrow sandy isthmus, alongside of which was the harbour which Leake takes to be that of Pala:ion: Melia: Borgi, on the southern shore of the isassic Gulf, between Myndas and Issaus, celebrated for its statue of Artemis Cypria, upon which, though exposed to the open sky, neither rain nor snow (it was said) ever fell. Issaus, or Issaus, now Askem, Asyn, Kalceos, on a small island at the head of the Iassic Gulf, was destroyed by Argive colonists, but received additional settlers in the time of Alexander; it became a wealthy place owing to its fisheries; part of the city walls and a theatre cut out in the side of a rock still remain. Brachida was famous for its oracle and temple of Apollo Didymus, on of which there are still some remains; the temple was robbed and burnt by the Persians (n. 494), but it was afterwards rebuilt. A sacred way led from the sea to the temple bordered with monolithic statues seated on chairs, the feet close together and the hands on the knees—and that of the last place of the line of the temple was called "a Asia Minor.") Brachidea stood near a harbour, called Panumus, on the south of the Possidion.

Miletus, one of the most ancient and flourishing towns of Caria and famous for its temples and statues and the numerous colonies founded by it on the Black Sea, was considerably destroyed by an earthquake, and on the south bank of the Meander and near its mouth. Its citizens were great traders and powerful by sea. They carried on long wars against the Lydian king. It was subjected to the Persians by Cyrus the Great, and notwithstanding its ancient and present condition continue prospers until the Roman revolt, instigated by their artistic colonize; this event brought them down to the vassalage of the Persians, who utterly destroyed it n. 494. It was rebuilt, and made a long resistance to the army of Alexander; but it never recovered its former importance, although it was a prosperous place under the Romans. Its site is marked by the modern village of Paliatis, where are seen the remains of an enormous theatre, an aqueduct, and a Christian church formed out of a Greek temple. South-east of Mileta, in the interior near the brackish lake of Baffi, which is probably part of the ancient Lacotamicus, was Heraclea in the western foot of Mount Latmus, where some ruins mark the spot. Near it was the cave of Endymion. To the north of this end of the lake, near the Meander, was Myrissa, and on the east side of Mount Latmus lay Amyrion, ruins of the city and walls of which remain. (P. Robert, Minor; Sir C. Fellows, Asia Minor; Hamilton, Researches in Asia Minor; Dictionary of Greek and Roman Geography.)

KARR, a town in Turkish Armenia, is situated in a high region, 6,600 and 7,000 feet above the level of the sea, on the Arpa, a feeder of the Araxes, about a straight-line distance N. E. from Erevan, N. W. from Bayand, and S. E. from Batoum on the Black Sea, in 40° 27' N. lat., 43° E. long., and has about 15,000 inhabitants. It is about 46 miles W. S. W. from the Russian town of Baku and 20 miles N. of the town of Tralles. There is good clay for making tiles and bricks, and large fields of sugarcane. The people are mostly Armenian, and the town is walled and has a citadel built by Amurat III.: but it is untenable against artillery, being commanded by heights within muse that range on the opposite side of a deep narrow ravine traversed by the Arpa. The two portions of the town are connected by a causeway, which is sometimes traversed by the river which encircles the walled portion of the town on three sides. Kar was formerly a large town with from 6000 to 8000 houses, but a great part of the Turkish population abandoned its during the Russian occupation (1853-56), and the inhabitants now consist of a few Russian army all the Armenians emigrated to the neighboring provinces of Russia; so that from Russian violence and the desertion of its inhabitants it fell into a state of ruin and decay.

Soon after the commencement of the late war between Turkey and Russia, General Quyon was sent to Kar at the end of 1853 as chief of the staff and president of the military council. He disciplined the Turkish army, and constructed defences. He was succeeded in 1854 by Lieutenant-Colonel Williams and in 1855 by Col. Sir John Keith, Turkish Majesty's Commissioner with the Turkish forces in the East. The defences were extended and improved, so that when the Russian General Mouravieff, who had invested Kar, attempted to take it by assault, Sept. 29, 1856, his father's day in the valley, however, after being reduced to the extremity of starvation, were obliged to capitulate. General Mouravieff treated the garrison, soldiers and inhabitants, as well as officers, with great humanity and kindness. By the treaty of peace concluded at Kar at Paris in 1856, Kar was evacuated by the Russian army, and restored to Turkey.

The picturesque of Kar includes the most northern part of Turkey in Asia, and the town is called the "capital of Caria" and in the "capital of Syria" in the "capital of Armenia." The town is said to have been founded by the Persians near the south of the Khor or Araxes, and from the Achaemenids to the modern town of Kar, which is the most ancient part of the Turkish dominion.

KAWRIE PINE. (Aparthis.)

KEITH, Benf休re, Scotland, a market-town in the parish of Keith, is situated in 56° 39' N. lat., 2° 40' W. long., on the banks of the small stream called the Iala, about 20 miles S. W. from Banff, 176 miles N. by E. from Edinburgh. The population of the town of Keith in 1851 was 2101.

The town comprises three distinct villages, called Old Keith, New Keith, and Keithburn. (L. Keithburn.) The castle of Keithburn is a large house, built by a nobleman of the Keith family, a very ancient village, and at one time was a royalty. It is now a mere hamlet. New Keith dates from the middle of last century. It consists of five principal streets, intersected by several smaller ones, with a square or market-place in the centre. It has many small houses and churches, a church house, an Episcopal and a Roman Catholic chapel, besides chapels for congregations of the Free Church and United Presbyterian bodies. There is a library and a savings bank. A grain-market is held weekly; and a cattle-fair, held annually, is the most important of which is "Summer Eve Fair." Fife Keith, a modern village, on the bank of the Iala, opposite Old Keith, with which it is connected by two bridges, consists of several well-built streets. Many of the inhabitants of Keith are employed in the manufacture of wools, flax-dressing, weaving, bleaching, and the manufacture of tobacco.

KELIADJE, a family of minute Molluscs belonging to the Littorinae, Asaphae, or Asaphid, and is the only species in this family between the Family Keliadje and Cyclostomata. The English Keliaede is known to the genera Montacuta, Turionia, Kelia, Lepont, and Galeone. The genus Kelia has two British representatives, K. subbifurcata and K. wiidio. They are small but elegant animals, living in the crevices of rocks, on shells or sea-weeds, spinning a byssus, or lying free. There are about a dozen species known in different parts of the world. This genus, from which the family takes its name, was named after Mr. O'Reilly of Dublin.

KELIS, WIMWIE.

KEMBLE, CHARLES, was born on the 25th of Nov. 1776, at Brecon (Brecknock) in South Wales. His father was Roger Kemble, an actor and theatrical manager. He was educated at the English Roman Catholic College at Douay, in the French department of Nord, whence he re-
turned to England in 1792. He was placed, through the influence of his brother, J. P. Kemble, in the General Post-Office, London, but soon resigned his situation, and after a few trials in private theatres, made his first appearance on the public stage at Sheffield, as Orlando in 'As You Like It.' He had engagements afterwards at Newcastle and other towns. On the 21st of April, 1794, he made his first appearance in London, as Malvolio, in the opening of the new theatre at Drury Lane. He afterward married Miss Macbeth, Mrs. Siddons Lady Macbeth, and Mr. Palmer Macduff. He continued for a considerable time to play secondary characters, but gradually improved in his art. On the:nth of November, 1796, he performed George Jones in 'Adoration of the Golden Calf', at Drury Lane, Mrs. Siddons playing the part of Millwood. In 1797 he was engaged at the Haymarket theatre, where in 1800 he brought out his adaptation of Mercier's 'Deserters,' under the title of 'The Point of Honour,' which was performed successfully, and became a stock-play. On the 2nd of July, 1806, he married Miss Marie Therese De Camp, of French parentage, but born at Vienna in 1774. Miss De Camp was engaged by her father as a danseuse at the Opera-House, London, at a very early age. Her father died when she was in her twelfth year; she was then trained and instructed by some ladies, and had become, when Charles Kemble married her, a favourite actress in the walk of high comedy, and she so continued as Mrs. Charles Kemble until 1821, when she quitted the stage in September, 1838. In 1807 Mr. Charles Kemble brought out with success at Covent Garden 'The Wanderer,' or the Rights of Hospitality; which is an adaptation of Kotzebue's 'Edvard in Schottland,' and in 1808, at the Haymarket, 'The Good Samaritan,' or 'The Country Counterplot,' an adaptation of a French piece called 'Le Portrait de Michel Cervantes.' Three or four other dramatic pieces from the German and French, which he brought out afterwards, were less successful. Meanwhile he continued to improve in his profession, and in 1810, when he was considered in his character was without a rival. Among his best characters may be mentioned Orlando, Falconbridge, Cassio, Leon, Benedick, Young Mirabel, Mercutio, Petruchio, Archer, Raffles, and Capt. Singleton. No British artist had such characters as his handsome features, fine voice, and tall well-formed athletic person, peculiarly fitted him. He closed his career as an actor on the 10th of April, 1840, shortly after having been appointed to the office of Examiner of Plays. He appeared in public occasionally afterwards as a reader of Shakespeare. During some of his latter years he suffered the inconvenience of deafness. He was well acquainted with modern languages, and a tolerable classical scholar. He died at his residence, No. 10, Newman Street, November, 1846, aged seventy years within a fortnight.

Mr. Charles Kemble left one son and two daughters. His son, John Mitchell Kemble, is noticed in a separate article. His eldest daughter, Frances Anne Kemble, known as Fanny Kemble, became a celebrated actress. She was separated from the other daughter, Adelaide Kemble, distinguished herself as an operatic singer. She became the wife of Mr. Sartoris, and then quitted the stage.

KEMBLE FAMILY. The Kemble family form probably the most extraordinary group of actors and actresses ever known. Macklin, when nearly 100 years of age, addressing John Philip Kemble, said, 'Sir, I have known your family from generation to generation. I have seen you and your father; I have seen your grandfather, and I have seen your grandfather, sir. Sir, he was a great actor.' The grandson of a grandson is the old song. Former Kemble (George Stephen Kemble), the third of the children, was born on the 3rd of May 1792, at Kingston, in Herefordshire. He was intended for the medical profession, and was placed with a surgeon at Coventry, but gave the preference to the stage. After a course of practice in the country he made his first appearance in London, at Covent Garden, on the 24th of September, 1753. In the same year he married Miss Satchell, a favourite actress. After acting for some time at Covent Garden he was engaged at the Haymarket. He became afterwards a member of a company that performed at Edinburgh and Glasgow, and subsequently of another that acted at Newcastle, Durham, Sunderland, Lancaster, and Whitehaven. He was a good actor, but became so hulky in person as to be almost unfit for any character. He became then nearly bankrupt, and migrated to London and the country. His last performance was in the character of Sir Christopher Carver, in the farce of 'Inkle and Yarico,' a few days after which he was attacked by inflammation of the bowels, and died on the 6th of June 1822, at the Grocers' Hall, London.

FRANCIS KEMBLE, the fourth child of Roger Kemble, was born on the 28th of December 1769, in the city of Hereford. She also became an actress, and performed in Lond-n; but having become the wife of Mr. Francis Twiss, quitted the stage. She died in 1812, at Bath.

ELIZABETH KEMBLE, the fifth child of Roger Kemble, was born on the 2nd of April 1781, at Warrington, in Lancashire. She was apprenticed to a mantua-maker, but left that occupation for the stage. After some practice in the country, she made her first appearance in London at Drury Lane Theatre, on the 22nd of February 1783, as Portia in 'The Merchant of Venice.' After repeating Portia she repaired to York, where she had previously succeeded in engagements in various parts of the kingdom, and her voice and address in the sweetest of English voices, and her striking resemblance to Mrs. Siddons. On the 21st of June 1786 she was married to Charles Edward Whitlock, an actor and joint-manager of a theatrical company in the north of England, known as the 'Old Joint Stock Company.' His wife was invested by Mr. Kemble with the management of the company, and Whitlock became the principal actress. The circuit of this company embraced Newcastle, Durham, Lancaster, and Whitehaven. Cooke and Munden were members of it before they appeared in London. In 1789 Mrs. Whitlock accompanied her husband to America, where she became almost as great a favourite as Mrs. Siddons was in England. She performed mostly at Philadelphia and Charleston, and frequently before General Washington. Having acquired an independence, Mr. and Mrs. Kemble were visited and entertained by Mr. Washington, and Mrs. Whitlock died about 1820, at 1830. Mrs. Whitlock was much admired in society for the liveliness of her conversation. She died on the 27th of February 1836.

The other children of Roger Kemble died young, except a daughter, Anne, born in 1764, who was alive in 1834.

KEMBLE, JOHN MITCHELL, well known as one of the chief Anglo-Saxon scholars of his age, and also distinguished as an actor, was born on the 17th of December 1745, at Chester. His great-grandfather, Charles Kemble, and was born in 1807. He was educated at Trinity College, Cambridge, where he took the degree of B.A. in 1830, and that of M.A. a year or two later. From the very first his studies were directed towards the Anglo-Saxon language and literature; and in 1857 he published his accomplishments in this department by the publication of 'The Anglo-Saxon Poems of Beowulf, the Traveller's Song, and the battle of Finnesburgh, edited, together with a Glossary and an Historical Preface.' The work reached a second edition in 1857, when an additional volume, containing 'A Translation of the Anglo-Saxon Poem of Beowulf, with a Glossary and Notes,' was appended to the first. The more important of Kemble's subsequent works, were the 'Codic Dictionaries and Catalogues of the British Museum,' published in 1839, vol. ii. 1840; 'The Anglo-Saxon Charters,' the 'Vercelli Codex; Poetry of the Codex Vercellensis, Anglo-Saxon and Latin, with an English translation,' published in 1849 as one of the works of the 'Elfin Society; the 'Dialogues of Solomon and Saturnus, with an Historical Introduction and English Translation,' published in 1848 by the same Society; an edition of Twyman's 'Considerations upon the Government of England,' published in 1849 by the 'Genseric Society,' 'A History of the English Commonwealth till the period of the Norman Conquest,' published in 2 vols. in 1848. This last work comprehends the main results of Mr. Kemble's Anglo-Saxon and historical studies. For a good many years Mr. and Mrs. Kemble were joint-author of the 'British Review,' a periodical of the highest class, which exercised considerable political and literary influence, but ceased to exist about the year 1845. He held the office of Examiner of Plays under the Lord Chamberlain, his acting assistant in this office being Mr. Donne. Mr. Kemble was a Fellow of
where it appears he did not distinguish himself. From thence he was entered at Caen College, Cambridge. Here again he failed to distinguish himself, for Cambridge had at that time no honours for those whose tastes led them to cultivate the natural sciences. He took his degree of B.A. in 1781; and having entered upon holy orders, was appointed shortly after to the cure of Barham, in his native county. In 1784 he married Miss Ripley of Debenham. At this time he examined Dr. Ray's new insects, whose writings on controversial divinity were highly estimated. Mr. Kirby had however no taste for polemics, and although he never neglected the duties of his office for the pulpit, his taste for the latter became so decided, that he published a few little objects directly connected with his profession as a clergyman.

Left to the natural bent of his genius, and surrounded with objects of natural history, his early love of plants was rekindled, and he cultivated a knowledge of the plants of his neighbourhood. An accident drew his attention to insects. "About half a century since," he says, in a letter to a friend in 1836, "observing accidentally one morning a very beautiful golden bug creeping on the sill of my window, I took it up to examine it, and finding that its wings were of a more yellow hue than was common to my observation of those insects before, I was anxious carefully to examine any other of its peculiarities, and finding that it had two as yet not noticed wings, and that the captured animal was imprisoned in a bottle of gin, for the purpose, as I supposed, of killing him. On the following morning, anxious to pursue my observation, I took it again from the gin and laid it on the window-sill to dry, thinking it possible that the animal to which it happened commenced my farther pursuit of this branch of natural history. These facts were communictted to Dr. Gwyn of Ipswich, who was a good naturalist, and led him to recommend to his young friend the pursuit of entomology. So diligent was Mr. Kirby in the pursuit of this new science, that he was able to find him warmly taking up the cause of natural history, and becoming one of the first members of the Linnean Society, founded by Sir James Edward Smith in 1787, of which he became President. In 1790 the Linnean Society. It was entitled 'A description of three new species of Hiruso,' and was published in the second volume of the 'Transactions.' His next paper, which was published in the third volume of the same Transactions, was 'A History of three species of Caxida.' In the same volume is a letter to Mr. Marham, containing observations on the Insects that infested the Corn in the year 1786. He became early alive to the importance of making the pursuit of entomology practical, and paid particular attention to those insects which attacked wheat, and other grain crops. The last paper was followed by others on the 'Tipula Tritica,' on 'Insects that prey upon Timber;' and in the fifth volume of the 'Linnean Transactions' is a paper entitled 'Observations on some insects of the genus Myrmele.' These and other papers indicate great accuracy of observation, and prepared him for a work of higher and more important scientific interest. The family of Hymenoperna, including the bees and wasps, had been but imperfectly studied in this country, and he devoted himself to the production of a separate and complete work on English Bees. This work was published at Ipswich, in two volumes, with plates, in 1809, and was entitled 'Monographia Apum Angliae, or an Attempt to produce a complete genera and families of the Linnean genus Aplis as have been discovered in England, with descriptions and observations.' This work embraced also general remarks on the class Hymenopera, and a table of the nomenclature of the external parts of these insects. The publication of this work at once gave him a high position amongst the naturalists of Europe, and brought him into correspondence with Fabricius, Leitirelle, and other naturalists on the continent of Europe, as well as all the more eminent naturalists of his own country. This work was followed up by a monograph of the recent literature of entomology, but was perhaps surpassed in scientific interest by his discovery of the genus Stylus, which he indicated as the type of a new order of insects, to be called Deuteropera, of which he found parasitical during their larva state in the bodies of bees, and the novelty of their history and beautiful forms excited a lively interest in the entomological world.

But whilst these discoveries were going on, he was preparing for a work by which his name became more widely known and imperishably associated with the popular literature of his country. We allude to the 'Introduction to Entomology,' which he published conjointly with Mr. Spence.

Mr. Kirby's acquaintance with the latter gentleman commenced in 1805, and resulted in Mr. Spence proposing a letter dated November 23, 1806, that they should write in partnership a popular introduction to Entomology. This proposition was readily acceded to by Mr. Kirby, and in November 1807 of this year the first edition went through three editions, and in 1817 the second volume was published. On account of the illness of Mr. Spence the third and fourth volumes did not appear till 1826. This work at once took a position amongst the classical productions of one who has added so much to the literature of insects. It is a model of the manner in which works on natural history to be popular should be written, and is almost exhaustive of the subject of the habits, uses, injuries, and instincts of insects. Of the fifty-one letters of which this work consists, it appears that twenty were written by Mr. Kirby, nine by Mr. Spence, and twenty-two by the two authors conjointly.

In 1830 Mr. Kirby was applied to by the trustees appointed under the will of the late Earl of Bridgewater to write one of the works since so well known as the 'Bridge-water Treatises.' Although he was then in the seventieth year of his age, the production of such a work was considered as a fitting task for a gentleman of his rank and attainments, and he at once commenced his farther pursuit of this branch of natural history. These facts were communicated to Dr. Gwyn of Ipswich, who was a good naturalist, and led him to recommend to his young friend the pursuit of entomology. So diligent was Mr. Kirby in the pursuit of this new science, that he was able to find him warmly taking up the cause of natural history, and becoming one of the first members of the Linnean Society, founded by Sir James Edward Smith in 1787, of which he became President. In 1790 the Linnean Society. It was entitled 'A description of three new species of Hirudo,' and was published in the second volume of the 'Transactions.' His next paper, which was published in the third volume of the same Transactions, was 'A History of three species of Caxida.' In the same volume is a letter to Mr. Marham, containing observations on the Insects that infested the Corn in the year 1786. He became early alive to the importance of making the pursuit of entomology practical, and paid particular attention to those insects which attacked wheat, and other grain crops. The last paper was followed by others on the 'Tipula Tritica,' on 'Insects that prey upon Timber;' and in the fifth volume of the 'Linnean Transactions' is a paper entitled 'Observations on some insects of the genus Myrmele.' These and other papers indicate great accuracy of observation, and prepared him for a work of higher and more important scientific interest. The family of Hymenopera, including the bees and wasps, had been but imperfectly studied in this country, and he devoted himself to the production of a separate and complete work on English Bees. This work was published at Ipswich, in two volumes, with plates, in 1809, and was entitled 'Monographia Apum Angliae, or an Attempt to produce a complete genera and families of the Linnean genus Aplis as have been discovered in England, with descriptions and observations.' This work embraced also general remarks on the class Hymenopera, and a table of the nomenclature of the external parts of these insects. The publication of this work at once gave him a high position amongst the naturalists of Europe, and brought him into correspondence with Fabricius, Leitirelle, and other naturalists on the continent of Europe, as well as all the more eminent naturalists of his own country. This work was followed up by a monograph of the recent literature of entomology, but was perhaps surpassed in scientific interest by his discovery of the genus Stylus, which he indicated as the type of a new order of insects, to be called Deuteropera, of which he found parasitical during their larva state in the bodies of bees, and the novelty of their history and beautiful forms excited a lively interest in the entomological world.

But whilst these discoveries were going on, he was preparing for a work by which his name became more widely
KIRKMUIR. [FORFAIRNERS.]

KIRTON. [LINCOLNSHIRE.]

KISCOENEF, or KICHEV, a town in European Russia, capital of the government of Bessarabia, is situated on the Byk, or Byon, a feeder of the Dniester, 40 miles N.W. from Bender and Tiraspol, on the latter river, 70 miles E. from Zinjan. It is called the, or settled by the Tartars, the Caucauss, Armenians, and Persia, and Baghdad. At this latter town he was detained during the plague. Mr. Grove there lost his wife, and Kito thence returned to England in June 1833.

In 1833, Mr. Woolcombe of Plymouth wrote a letter of introduction for him to Mr. Coates, the secretary of the Society for the Diffusion of Useful Knowledge recommending him for employment on the 'Penny Magazine.'

The year 1823 began with the publication of the 'Pictorial History 1861-63.' KIRTON.

The town is adorned with handsome marble fountains, and has a fine public garden. The inhabitants consist of Russians, Greeks, and Greeks, and gipsies, carry on a considerable trade in corn, cattle, sheep, hemp, tobacco, fruit, wine, &c. The principal industrial products are brandy, leather, soda, candles, some woollen stuffs, &c.

KITTA. [Convo.]

KIT6'S, St. [CHRISTOPHER'S, St.]

KITTO, JOHN, was born at Plymouth, December 4, 1804. His father had been a respectable builder, but soon after his son was born he was reduced into circumstances through the adoption of intermate habits. At four years old John Kito was transferred to the care of his maternal grandmother, by whom he incepted was called into activity by the relation of marvellous stories, and by leading him to notice and admire every remarkable object around him in the fields and woods. He early learned to read, and read with avidity all the books he could procure. By the time he was twelve years old, his father had descended to the rank of a jobbing mason. He was unable to keep his son at school regularly, who, whenever he could be made avail of, was required to attend his father in his labours. On February 13, 1817, having ascended a ladder with a load of slates, he fell from a height of thirty-five feet. He was taken up senseless, convulsed, and in a frightful state of insensibility. He recovered, but was himself unaware at first that he was deaf. He wondered at the silence around him, and, at length, asking for a book, was answered at first by signs, and next by writing on a slate. He inquired with astonishment, "Why do you not speak?" His attendant wrote again, "You are deaf." No efforts could restore his hearing. He still continued his reading, but in 1818 his grandmother obliged to quit Plymouth, and he was left to seek for a livelihood with his father, who was engaged in the wine business, and lived with his parents in a state of great destitution. At length, on November 15, 1819, he was placed in the house of a relation, where he was treated with much indulgence, and began to learn shoemaking. His deafness occasioned him to work at this art with great promptness and facility. In August 1820 he commenced a journal, which he continued till January 1822, and he was encouraged to write lectures which were read to the other boys. In 1821 his grandmother died, which event made a great and serious impression on his mind. In November 1821 he was apprenticed to a shoemaker; but his master was harsh, he was somewhat awkward, and still passionately devoted to reading. Finding himself uncomfortable, he wrote to some of his friends, and after pleading his cause in writing before the magistrates, he was taken back to the workhouse in May 1822.

Early in 1823 he wrote some essays which were published in Nettleton's 'Plymouth Journal,' and he also wrote some imaginary correspondence. In April 1824, Mr. Grove, a dentist, who had known something of him in Plymouth, but who was then settled at Exeter, engaged him in order to teach him his art, and he accordingly removed to Exeter, where he succceeded in attaching Mr. Grove to him as a student. In 1825 he published his first volume entitled 'Essays and Letters, by John Kito.' It produced but little profit, but it contributed to make him known, and excited the interest of many of the inhabitants of Exeter. By their efforts, greatly assisted by Mr. Grove, he was admitted to a fellowship of the College of Surgeons at London, and there to be taught printing, which it was thought might render him useful in some of the missionary establishments abroad. In 1829 he entered into business in July 1825, and was dispossessed of his printing office in June 1827, but his health being unequal to his work, he returned to England in February 1829. In the following May he agreed to accom-
whom he had a large family. She was a most effective assistant to him in his literary labours, and a seductress prompted his affection by the publication of her late husband, prepared by the Rev. J. E. Byland, founded on materials left by himself either in the form of journals or of letters.

KLAENBURT. [Clagenfurt.]

KNOTT-GRASS. [Polygono, S. 1.]

KOBELLITE. [Mineralogy, S. 1.]

KOLLAR, JAN, a poet and preacher, the originator of the idea of Panaslovism, was born on the 29th of July 1793, according to his son's account, at Mostovce, in the county of Trenschin in Hungary, being born a Slovak, or one of the Slavonic races of northern Hungary, who speak a language akin to that of their fellow-countrymen living at Belgrade in Serbia, and Jena, he became in 1819 pastor of a Slovakian evangelical congregation at Pesth. In 1823 and 1827 he issued a two volumes, under the title of 'Narodniz Zpievawsky, or National Songs,' an interesting collection of the popular poetry of the Slovaks, which reached a second edition, with additions, in 1834 and 1835. Unlike some other Slovakian authors however, he was far from exhibiting a narrow and exclusive attachment to his native dialect. Considering the Slovaks as too circumscribed in its range to be equal to the dignity of literature, he devoted himself to the writings the Bohemian, though it was at the time rejected for German in Bohemia itself by several of the native authors. In 1821 he published at Prague a volume of 'Slezky' (Poems), and in 1824 at Buda, a new edition, under the title of 'Slavny Dercy' (The Daughter of Glory). The copy of the second edition, in the British Museum, formerly belonged to Bowring, to whom it was presented by Sadařik, and who has written in it, 'This is a most remarkable book, and how its true and fiery spirit should have burst this Austrian censorship is altogether unintelligible to J. B." The leading ideas of the poems is that of the common bond of union between the Slavonic nations, and the work has an influence on consequences not less lingering than in any previous one. The same idea pervades the 'Cestopis' (Pesth, 1843), a record of a journey to Upper Italy, the Tyrol, and Bavaria, made by Koller in 1841, chiefly for the purpose of discovering traces of Slavonic antiquity.

Among his other productions is a volume of sermons, 'Kame' (Pesth, 1851), which were found so eloquent that they were translated into several languages. Kollar was obliged to leave Pesth by the revolution of 1848, and must in the same year have seen many of his hopes destroyed by the breaking up of the Slavic Congress at Prague by the action of Windischgrätz. In the next year he was, probably by way of compensation, named professor of archaeology at the University of Vienna. In 1851 he made a journey to Moskow to study the relations of the Ounavus, and on his return to Vienna was surprised by death on the 26th of January 1852, when he was preparing for the press a German work, 'Das slawische Altaitalien,' intended to prove that the ancient inhabitants of Italy spoke a Slavonic

The work of Kollar which is chiefly admired by his admirers, is his 'Slavny Dercy,' which in its latest shape, as it appears in his "Dils Bäaicki" (Poetical Works) published by his son in 1844, is a volume of 56 cantos, and extends to 692 sonnets, having little exception except the common idea of 'Panaslovism' which pervades them. Whatever the merit of some of the earlier portions, there can be no doubt that some of the later additions are scarcely inferior to the former, and were related to awoken respect for the works; in particular some coarse attacks on Mr. Paget and Miss Pararo, apparently dictated by a feeling of resentment at their having spoken well of the Hungarians. The prose works of Kollar contain very little information, which is however disfigured by an occasional aberrant observation; but the spirit of mere Slavonic nationality. Several of Kollar's sonnets are translated in Sir John Bowring's work on the Bohemian poets.

KOLLYRITZE. [Mineralogy, S. 1.]

KOLN, or CULN.

KONIYEH (Koniah, Koniah), a city in Asia Minor, capital of the pashalik of Karaman, which includes the greater part of Phrygia and Paphylia, is situated in a wide plain in 37° 54' N. lat., 32° 40' E. long., 305 miles E. by S. from Smyrna, and 155 miles N. from Kaflin, near the Arabian Sea. Population, 30,000. The town is surrounded by walls built with well-cut blocks of stone, and strengthened by square towers, some of them richly ornamented with cornices, arabesques, lions' heads, and Arabic inscriptions. To rise from the brink of a wide fossè, it is approached by hand-some gateways, some of which are constructed with fragments of ancient structures. Within, the city, when seen by Hamilton, presented little except ruin and decay; large spaces lay covered with heaped dilapidated mosques and deserted houses. The modern town and the bazaars occupy the more eastern part of the site, where also is the konak, or palace of the pasha. The houses are low, and mostly built of sun-dried bricks and wood. The old castle, which stands in the centre of the town, is a ruin, its upper stories having been removed to build the pasha's konak. Koniyyeh contains many beautiful remains of Saracenic architecture, among which may be mentioned the mosque of Sultan Bekir, the house of the late Memi Minareh Djamî (Mosque with the Minaret reaching to the Stars), which is exquisitely adorned with delicate tracery, fretwork, and monilings. The minarets are chiefly of glazed tiles and bricks of various colours, red and blue prevailing. The old Japanese prison, the largest building in the town, is an interesting half-ruined structure, bearing some resemblance to a gothic castle with its ruined towers, battlements, and keep. The pasha's konak is a large straggling building approached by a rather circuitous way between extensive burnt grounds, part of the old castle having been removed for a century. The other objects of note in the town are its large bazaars, several medresseh, or colleges, several sepulchral chapels, a few Armenian churches, the public baths and khans, and the tomb of a Moslem saint venerated all over Turkey. The manufactures are confined to carpets and blue and yellow marocco leather. Cotton, wool, and skins are sent to Smyrna. The immediate neighbourhood of the town is belted by a small breadth of garden-ground, which is kept in a state of verdure by irrigation. Other districts are a wide thirsty desert; in winter flooded and impassable. The city is supplied with fruit and vegetables chiefly from the Greek village of Ziliez, which is two hours' distant, and situated among picturesque gorges among the mountains. This village is inhabited by about 5000 Greeks, descendants of the ancient inhabitants of Konyeh, who were driven out and obliged to settle here by the Turks when they captured the city.

Koniye is the ancient Iconium, which Xenophon says (Anab., i. 2) was in Phrygia; in later times it was considered the capital of Lycaonia. Under the Romans it seems to have risen in importance. Gicero spent ten days in Iconium on his way to Sardica (Epist. ad Atticum, v. 20). In the first age of Christianity it is described as a populous city inhabited by Greeks and Jews. St. Paul and St. Barnabas preached in the synagogue of Iconium. Under the Greek emperors the city continued to be the metropolis of Lycaonia; but it was destroyed by the Goths, and afterwards by the Seljuk Turks about a.D. 1075, who made it the capital of their dominions. Under the Seljuk Turks, and during the period of the Crusades, Iconium acquired its greatest celebrity. The Seljuk dynasty and power terminated in 1224. After the period of anarchy the city was seized by Othman, the founder of the Ottoman empire in Asia, which had Brusa for its capital. From this time Konye declined rapidly. Ibrahim Pasha, commander of the Turks in Egypt, in 1832 completely defeated the Turks near Konyeh, December 20, 1832.

A Christian synod held at Iconium about a. D. 320 pronounced against the validity of heretical baptism. Koniye is looked upon by the Muslems as a sacred city; many devotions are re-
Greek and Roman Geography; London Geographical Journal, vols. viii. and x.; Conversations-Lexicon; L'Art de Vérifier les Dates.

KOSTENDJIE, or KOSTENDJIE, a sea-port town or rather village, 1848, and within the Canton of Geneva, is situated in the Bruderingen, the eastern termination of the fortification called Trajan's Wall, 226 miles in a straight line nearly due north from Constantinepollo, and about 40 miles E. from Resson. The town, which consists of about 550 houses, is built on the west shore of a basin being one of the few remaining episodes of horizontal rock, which rises precipitously from the sea to the height of about 100 feet, and shelters the harbour on the northern side. The harbour is exposed, except on the north side, and ill adapted for navigation; the water only 7 feet deep is not navigable. It occupies the site of an ancient town, Constantinia, which is said to have been founded and named from Constantine the Great. It retains in its ruined mule traces of Roman masonry. The town has some trade in corn. The project of opening a channel for the Danube across the Dobrudjeha is by the chain of lakes called the Kara-Sn into the harbour of Kostendjie has been often mooted. [Dukardinia, S. 2.]

KÖTHEN. [Köthen.]

KÖZEPP. [Esztergorn.]

KRAIN, or CARNIOLA, a crownland of the Austrian empire, is bounded N. by Carnicia, E. by Styria and Croatia, S. by Croatia and the Kistland, and W. by Friuli and the circle of Gorra. The area is 5538 square miles, and the population about 462,000. The surface is extremely rugged and mountainous. The principal chain of the Carnic Alps penetrates into the north-west of the crownland, where it terminates in the mass of Mount Terglou, the highest point of which rises to 10,909 feet above the sea level. The land which borders the north of the crownland is covered by an offset or continuation of the Carnic Alps, which springs from the main chain near the village of Weissenla in the north-western angle of the crownland, forming the watershed between the Drava and the Save, and running in a general south-east direction between Carnibia and Carniolla, through Croatia and Slavonia, where it terminates in the valley of the Danube. This range, which is distinguished by different names, covers with its ramifications the greatest part of the crownland, and forms the main boundaries of the Save, its highest points being the Leoblerberg (4747 feet), the Sattelberg farther east, and the Steiner Alps to the north of the village of Stein, which rise 10,000 feet above the level of the sea. These mountains are distinguished by their singular forms, and consist of steep, rough, and for the most part naked masses of limestone, with scanty vegetation and little timber. They are crossed by three roads, one from Villach to Laybach by the Wurzen Pass and the Upper Sautal, another by the Klagenspass, joined by the Leobler or Loibler Pass (4032 feet); and a third from Marburg and Celj to Laybach by the Trojana Pass, which is also traversed by the Vienna-Trieste railway, now open as far as Ljubljana, which rises in the northern part on the Carnic Alps and the chain that forms their continuation south-eastward, the Save has its rise in the glaciers that cover the northern flanks of Mount Terglou.

The central and southern parts of the crownland are covered by the Julian or Krainer Alps, and their ramifications. The Julian Alps run south-east from Mount Terglou between the Upper Save and the Iszno to Mount Kleek in Croatia, reaching the height of 7458 feet above the sea in the Sutkain, and close to the Carstian frontier. A branch runs southward from the main range on the northern and eastern edge of the peninsula of Istria; and along the western side of this ridge to the south of the Wippach extend a stony wilderness called the Karst, which is a plateau of limestone rocks abounding with strange clefts and fissures and funnel-shaped cavities, infested by furious winds, and almost entirely destitute of vegetation. In all this region there is not a single tree; in a few sheltered spots a little grass has grown; and the vine is seen to creep along the crevices of the rock. The Naas-Mountains (4000 feet) near Wippach with the main chain of the Julian Alps, here called Brinbaumber,er. From the Schnelberg a branch of the Julian Alps runs between the slopes of the Gark, rising in the summit of Jauerinj an elevation of above 6000 feet, and stretching up to the Save in the most eastern part of the crownland. The Julian Alps consist of granitic limestone which is shattered into rugged fragments, rent by chasms, and full of grottoes, caves, and underground passageways, abounding with the most beautiful stalactites. The rain that falls and the snow that melts upon them, form streams, which for the most part flow in subterranean channels, and the want of moisture at the surface gives these mountains an aspect of the most monotonous sterility. The rain falls freely to 10000 feet and the caverns in the Julian Alps, the most celebrated of which are those in the neighborhood of Alzannino. [S. 1.]

Immemorable rivulets disappear in the calcareous soil, and appear in the north on the mountain streams only after more than once into the chasms, which intersect the surface of the region, and pursue for a time an underground course. Nevertheless, some of the valleys present picturesque scenery, especially those of the Save and its feeders, and the Wippach. The lake of the Save, called the Idria, is formed by the course of the Idria, which has its source near the town of Laybach by the Adelberg Pass (3159 feet) across the Karst to Trieste. This last is intersected by a road from Görz through St. Veit, and Senoset to Fiume. Except in the river-valleys which form a comparatively small portion of the surface, the soil is very unfruitful, naked mountains, rocky levels, marshes, or sandy flats, being the prevailing characters of the country. The climate on the mountains and uplands is sharp; the winters severe and long; snow disappears from the mountains tops only in the height of summer. The Bora, or north-east winds, at times sweep the Karst and the more exposed parts of the country with furious violence. In the gorges and valleys the soil is much better; oaks, beech, and chestnuts abound, and vineyards are limited to use of the melting-furnaces. On the mountains many rare Alpine plants, medicinal herbs and roots are found. Horned cattle and horses are small; swine and poultry abound. Among the wild animals are deer, wild boars, the chamois, fox, weasels, martens, and marten. Rare. Birds of prey are numerous. Of game-fowl the principal kinds are pheasants, bustards, partridges, snipes, and water-fowl. Among the minerals the most important are iron, quicksilver, copper, lead, clay, alum, coal, marl, and iron. The forests are well wooded, sandy and whet stone. The mines of Idria in the west of the crownland, have been long famous; the entrance to them is in the middle of the town of Idria; they formerly yielded 16,000 cwts. yearly. The industrial products consist principally of woollen, woollen-cloth, woollen, iron and steel articles, such as scythes, sickles, naths, files, &c.; copper articles, woolen-cloth, leather, linen, face, pottery, paper, straw-hats, canvass, horse-hair sashes, tiles, German tinder, &c. A good number of the population are employed in mining and metallurgy. There is a considerable trade in timber and firewood.

The principal rivers are the Save and the Iszno. The Save, or Sava, rises on the northern bank of Mount Terglou, and runs first eastward along that mountain chain, then south-west to the town of Sautal, and there at a distance of 12 miles enters the Sava-s; its course is then south-west to the north-east to the south-westward of Laybach, in which the river Laybach joins it on its right bank. The river then runs eastward till it reaches the boundary, along which it runs in a south-easterly direction till it enters Croatia a few miles below its junction with the Gark, which passes Neustadl. The Iszno (the ancient Esonus) rises on the southern slope of Mount Terglou, from which it runs south-east through the eastern part of Carniola and 12 miles south of the town of Sautal; at a distance above Aquileia the Iszno divides into two branches, the Issonato and the Sodbo, which inclose the isle of Morosina, and after their re-union enter the Gulf of Trieste. The principal feeders of the Iszno are, on the right, the Torre, which drains a part of the province of Friuli, and on the left the Idria and the Wippach, both of which flow in a north-west direction, the former passing the town of Idria and entering the Iszno above Canal, the latter falling into the sea between the Mont Drava and the Iszno. The Iszno is subject to inundations on the melting of the snow in spring and after the autumnal rains. The Save is navigable in Carniola, and a river-port has been formed at the mouth of the Save, which is navigable by vessels of small size. The Iszno formed part of the eastern boundary of Italy under the French empire. The Laybach, above mentioned, rises near the south-east corner of the crownland, and runs through a deep valley to the border of Croatia, where it is navigated by means of small boats.
Adelberg under the name of Poll: this stream loses itself in the grotto of Adelberg and reappears in the Uns, which again sinks below the surface, but reappears at the village of Ober-Laybach, where it becomes navigable for boats. The remarkable Lake of Cirkinitz, or Zirkinitz, is noticed in a separate article.

The crownland is divided into 10 circles. With the exception of Laybach and Idria the towns are small. Laybach, or Lay, the capital of the crownland, is situated in 46° 2' N. latitude, and 13° 4' E. longitude, and separated from Vienna by the Vienna-Trieste railway; in an extensive valley near the mouth of the navigable river Laybach, which divides the city into two parts, connected by five bridges; and has with its suburbs about 15,000 inhabitants. It is administered by a mayor, five aldermen; and has a town council, two churches, a lyceum, a gymnasmium, and many other public institutions. The chief industrial products of Laybach are porcelain, linen, and refined sugar; there is an active transit trade, also to Trieste, in which direct railway is in course of construction. The citadel, situated on a commanding eminence, is now used as a prison. At a short distance to the north of the town there is a stone bridge of 11 arches, 540 paces in length, over the Save. Laybach is the educational centre of the crownland.

The other towns are Stein, which gives its name to the Steiner Alps, from the summits of which, 10,274 feet above the level of the sea, there is a magnificent prospect over Carniola; Kainzburg, with the castle of Kesselstein; Neumarkt, where there are revolutionary and constitutional pamphlets, f. c.: none of these towns have so many as 2000 inhabitants.

Neustadt, the capital of a circle, is beautifully situated on the river Gurk, 35 miles E.S.E. from Laybach. It is a very pretty regularly-built town, with three churches of a gymnasium, a Franciscan convent, and about 5000 inhabitants.

The other only place of importance is Idria, a mining town, famous for its quicksilver mines, which were accidentally discovered by a peasant in the year 1497. It is situated partly at the bottom of a fertile valley, partly on high mountains, 22 miles W. from Laybach, on the banks of the little river Idria, and partly on several low hills, of which that called Mount Calvary is distinguished by its height and picturesque form. The town is inhabited by 400 and 500 houses, and has about 5000 inhabitants, who subsist partly by lace-making and straw-plaiting; but the greater part are employed in the mines and works. A large building called Schloss, in the middle of the town, contains the offices of the manager of the mines; close to it is the entrance to the mine by a large iron gate, which opens to a horizontal passage hewn in the solid rock, leading to a flight of 707 steps, ent in the limestone rock, which are kept in perfect order and provided with a hand-rail. At the foot of this staircase there is a basin and large vats in which the miners perform their deviations before they proceed into the mine, and where a couple of tapers burning on the altar help to cheer the gloom that reigns in these subterranean caverns. The church of the Schloas, or Casel church, contains many baroque altars running in all directions, and would soon be bewildered in the labyrinth without a guide. This mine is one of the greatest curiosities in the Austrian empire, and unequalled for the order, beauty, and safety which are remarked in every part. The notions exhalations of the quicksilver, which sensibly affect respiration, and the enflaming heat, soon make the visitor anxious to return to the light of day, to which he ascends by a perpendicular shaft in a height of 220 feet. The famous mine town of Zirknitz, in earth, at a great distance from the spot at which he entered. The deepest depth of the mine is 750 feet. About 100 tons of mercury are produced annually. The stamping-mills, washing-houses, furnaces, and roasting-houses for the refining of the mercurial ore are at a short distance below the town. Besides the quicksilver-works there is a manufacture of cinnamon, which produces 1800 cwts. annually. In the vicinity there are marble, Jasper, and freestone. All the establishments for smelting, refining, &c., are admirably arranged, and the building is elegant. A little above, in a hollow, is a small town whose health is most dreadfully impaired by the detestable atmosphere in which they ply their sickly trade. These mines, the groottes of Adelberg, and the Lake of Cirkinitz, are the principal sources of Idria's wealth.

Carniola was, until the political arrangement of the Austrian empire in 1849, divided into the three circles of Laybach, Neustadt, and Adelberg, which corresponded with the older divisions of Upper, Lower, and Inner Carnia respectively, and formed the government of Laybach. Krain was early inhabited by a people of Slavonic stock, and formed in the 10th century an independent magistrature, which at a later period the dukes of Austria and Carinthia divided between them, and which was raised in the 12th century to a dukedom, which the Duchy of Tyrol in 1335 fell to the Earl of Görz, from whom it came, through failure of male issue, to the house of Austria in 1861. By the treaty of Vienna in 1809 Krain was ceded to France, for the benefit of the Illyrian provinces. In 1813 it again came into the possession of Austria, and formed part of the kingdom of Illyria. [Ilytma.] Krasinski, Count Valerian, was a native of the ancient Polish province of White Russia, and was descended from a noble Polish family. He was educated at a very early age, and early embraced at an early period the Protestant faith, to which he adhered. He received a superior classical education, and while yet a young man was appointed chief of that department of the ministry of public instruction in the kingdom of Poland which was charged with the superintendence of the various classes of dissenters. He was zealous in his endeavors to promote instruction among them, and especially exerted himself in the establishment of a college at Warsaw for the education of the peasantry. In 1821 he married a lady of the family of Laybach, and removed to Carniola, where he resided during the first twenty years of his exiile, and during the last five in Edinburgh, where he died December 22d, 1855. He was a man of varied learning, and possessed a correct, concise, and forcible style of expression, especially on all matters connected with the Slavonic races. His conversation was instructive and his manners elegant, and he was admitted to the best society.

His most important works are the following: 'The Rise, Progress, and Decline of the Reformation in Poland,' 3 vols, 8vo, 1829-40; 'Panasiavism and Germanism,' 12mo, London, 1848; 'Lectures on the Religious History of the Slavonic Nations,' 8vo, London, 1849; 'Sketch of the Religious History of the Slavonic Nations,' 8vo, Edinb., 1851; 'Montenegro and the King of Montenegro in Prose, and 'A Treatise on Relics, by J. Calvin, newly translated from the French Original, with an Introductory Dissertation on the Miraculous Images of the Roman Catholic and Russo-Greek Church.' His principal works are pamphlets on current political subjects, especially on those connected with the restoration of Poland.

Krokydolite. [Mineralogy, S. L.] Kugler, Franz Theodor, Professor of the History of Art in the Royal Academy, Berlin, was born on the 19th of January 1806, at Berlin in Pomerania. On the completion of his collegiate studies Herr Kugler especially devoted his attention to the early history of painting and architecture, and prepared himself for a purpose which has led him to the study of ancient and subsequently visited Italy. Poetry and music also occupied much of his attention, and he in 1830 gave evidence of his attainments in these arts by the publication of his 'Sketch Book,' in which he included original compositions in poetry, music, and linear design; it was published with Reinick an artist's song-book. But the more important as well as the most numerous of his writings about this time were those on the history of art during the middle ages; though the arts of ancient Greece and Rome (and particularly the art of Constantinople) have also been treated with interest. He published 'Uber die Polychromie der griechischen Architektur und Sculptur und ihre Grenzen,' 4to, Berlin, 1835) also engaged his pen. His great work the 'Handbuch der Geschichte der Bildenden Kuenste' (1829-51) was published. 'History of Constantine to the Present Time' appeared in 3 vols. in 1837. It was received with great approbation by his learned contemporaries and by students of art generally, and was quickly translated into the leading languages of Europe. In
LABUAN, an island in the Malay Archipelago, and the seat of a British colonial government, is situated on the north-east coast of the island of Borneo, and 30 miles N. from the town of Borneo, in 5° 32' N. lat., 115° 10' E. long. The island is about 10 miles in length, 5 miles in breadth, and 25 miles in circumference. The population in 1856 was 46,966. The island is well supplied with good water, and contains coal. It was ceded to the British in 1846, and the colonial government was established on it at the beginning of October 1848.

The locality on which the government establishment was formed consists of a narrow and slightly raised ridge on the sea-shore, forming the outer edge of a low flat, called the Plain, which is in many parts below the level of the sea, and was converted into a marsh during the rains. The area of the Plain probably does not exceed 100 acres. It is bounded on the inland side by swampy tracts of jungle. The harbour is tolerably good. The unhealthiness of the marshy ground in the Plain has been considerably abated in consequence of the construction of a canal, by which the water is carried off.

The coal is wrought on the north-east coast of the island. The mines have been taken by the Eastern Archipelago Company, which in 1851 exported 6032 tons of coal, of which a large part was supplied to vessels belonging to the British navy. During 1862 and 1863 they employed 280 Zels (aborigines) and negroes, at a remuneration of 65s. per man per month, and cleared outwards 27, of an aggregate burden of 5635 tons. The imports in 1852 were valued at 30,970£; the exports at 16,542£, the principal exports were:—Coal, 5643£; sago, 2879£; bird's-nests, 1937£; pearls, 1805£; and camphor, 1659£. The principal item of revenue is the royalty on coal. Farm licences are increasing in value, improved rentals being obtained at each succeeding sale.

LACHMANN, KARL, professor in the University of Berlin, and member of the Academy of Sciences, occupied a high rank among the critics and philologists of Germany. He was born at Brunswick on the 4th of March 1793. In that year he received his early education under his teacher, Konrad Heusinger, who was then one of the most celebrated practical grammarians of Germany. In 1811, Lachmann was the first among the younger men who directed Lechmann's attention more particularly to it, and he was afterwards much more critical upon it and upon many of the early Greek writers. During the short war occasioned by Bonaparte's return from Elba to France in 1815, Lachmann served as a volunteer in the Prussian service, in which he continued till the end of that year. In the spring of 1816 he was appointed as a lecturer at Göttingen, was published at Leipzig; and at Easter of that year he read his probationary essay before the University of Berlin. "Ueber die urprüngliche Gestalt des Gedichts von der Niebelungen Notd'" (On the Original Form of the Poem on the Niebelungen Calamities). After this he was appointed, in rapid succession, teacher at the Gymnasium and professor at the University of Königsberg, and professor of the University of Berlin, the last promotion being attained in 1827. Highly esteemed as an academic teacher, and sedulous in the discharge of his duties, he nevertheless actively continued his literary labours. Many of these were critical or philosophical essays contributed to periodical works. Of his distinct works, the more important have been "Die Geschichtedes der Greco-Romanischen Literatur (vom bald der Germanischen bis auf die altorientalischen," which are both masterly specimens of criticism. His last was the substance of two lectures delivered before the Berlin Academy in 1838 and 1841. In 1844 and in 1842 he published two editions of the New Testament, the last with the Vulgate translation, in which he endeavoured to restore the text to that of the 3rd and 4th centuries. In the classical department he published: "De Choricis Systematis Tragicorum Graec., Berlin, 1819;" and "De Memoria Tragediorum," Berlin, 1828; with carefully-prepared editions of Catullus, Tibullus, Terence, Bœbrus, and Avianus, at intervals from 1829 to 1845; one of Oisias, so important to the students of the Roman jurisprudence, in 1841; and essays upon Deuthers and Ulpian in the ninth volume of his "Geschichtedes" of the Roman Law, published in 1826. Most of his works have gone through more than one edition. His attention however was never diverted from the early literature of the north of Europe. In 1816 he translated the first volume of P. E. Müller's "Sagabibluthet," in 1830 a selection from the High-German poets of the 13th century; in 1836 an edition of the "Niebelungen Lied"; in 1837 an edition of the poems of Walther der Vogelwede; in the same year, in conjunction with Benecke, an edition of Hartmann's "Twain;" in 1833, an edition of the poems of Wolfram von Eschenbach; in 1838, Hartmann's "Gregor," and the poems of Ulrich von Liechtenstein, 1841. These were all prepared with great care, and accompanied with valuable remarks. He also contributed numerous papers to the "Zeitschrift für die gesammten Wissenschaften der Alterthümer" of the Berlin Academy. The most noticeable are "Ueber altdeutsche Bettonung und Verkunst," (On the early High German Accents and Verkunst.) And," Ueber Singen und Sagen," and "Ueber das Hildebrandlied." He also published an excellent critical edition of Lessing's collected works, in 13 vols., Berlin, 1838-40; and an edition of Kleines's "Philologische Essays." Lachmann is likewise the author of a translation of Shakspere's sonnets, published in 1820; and of "Macbeth," published in 1850. He died in March 1851.
the system of the Abbé Lamennais, and to explain that it combined the advocacy of the interests of the Roman Catholic Church, and the defence of liberal opinions in connection with it; and to maintain that religion, so long neglected, and suffered to decline by the upper classes, ought to be, and might be replaced by the people, if the government were so disposed. This was a complete separation of the spiritual from the temporal power, insisting that political influences ought to be transferred to the multitude by means of the press and of public meetings, expressed in a style of eloquence, somewhat biblical in form, and unanswerable.力 produced, upon an excitable people an effect so manifest as to provoke the censure of Rome, in the form of an encyclical letter, of the 18th of September 1832. Having received a gracious letter of congratulation from the pontiff on the 30th of December.

But in May 1834, the new champion of independence in Church matters produced his most admired book, the *Paroles d'un Croyant,* a pathetic lamentation, addressed alike to the suffering classes, and to the great and powerful; a work which so tended for ever the bond that united Lamennais to the see of Rome. Irritated by this new provocation, Gregory XVI, in a last despatch dated January 1834, but superseding his journal, had received a gracious letter of congratulation from the pontiff on the 30th of December.

In this book he denounces the materialism propagated by the philosophers of the 18th century, and bitterly deplored the apotheosis induced to religion. His vocation being the Church, he found the Church, of his own sect, in 1811; and in 1812, in concert with his brother, published his *Tradition de l'Église sur l'Institution des Évêques.* As the power of Napoleon I. was dissolving, and the times seemed propitious for the diffusion of unfettered thought, he went to Paris in 1824, where, for many years, he declined his father's repeated offers to settle him in some mercantile office, and in 1807 found means to enter the college of Saint-Malo, as teacher of mathematics.

In one of his early works, *Réflexions sur l'État de l'Église en France, pendant le 16 Siècle, et sur sa Situation actuelle.* In this book he denounces the materialism propagated by the philosophers of the 18th century, and bitterly deplored the apotheosis induced to religion. His vocation being the Church, he found the Church, of his own sect, in 1811; and in 1812, in concert with his brother, published his *Tradition de l'Église sur l'Institution des Évêques.* As the power of Napoleon I. was dissolving, and the times seemed propitious for the diffusion of unfettered thought, he went to Paris in 1824, where, for many years, he declined his father's repeated offers to settle him in some mercantile office, and in 1807 found means to enter the college of Saint-Malo, as teacher of mathematics.

LAW, CRIMINAL. Upwards of 65,000L has been spent on
various commissions, which have been issued during the
last thirty years for the consolidation or codification of the
criminal law. These works, though not yet attained, may
have not really practical measures been adopted for such an
annual revision of our statutes as would in a few years
naturally produce their consolidation, if not a codification of
the same. The present state of the Legislature and the
impotence of the House of Commons will before long compel
the passing of general acts consolidating and so far codifying
the criminal law; on this ground it is desirable to abstain
from any attempt to enumerate those alterations in details
which have been made. One of two points only need be
referred to. The summary jurisdiction recently
conferred on magistrates in petty sessions is noticed under
LACENY, S. 2; the liability of trustees to prosecution for
breach of duty, under the head TRUSTS, S. 2. Great improve-
ments were effected in the procedures of the courts which
take cognizance of crimes by the statute 14 & 15 Vict.
c. 100, which abolished all technical objections for misnomers
or nondescriptions, and invested the judges with ample
powers of amendment. Finally, transportation as a punish-
ment to be ordered by the court has been abolished by the
statute 20 & 21 Vict. c. 3. Penal Servitude, as it is termed,
created by statute 16 & 17 Vict. c. 99, has been substituted;
but criminals sentenced to long terms of penal servitude
continued to be sentenced under the old laws.

LECHLAEDE. [GLOUCESTERSHIRE.]

LEE, REV. SAMUEL, D.D., was born May 14, 1763,
at Longnor, a village in Shropshire, about eighteen miles
from Shrewsbury. He received the rudiments of education
at a charity-school in that village, where, at the age of twelve
years, he was apprenticed to a carver. At the age of seventeen he formed a determination to learn
the Latin language, and though he had at first only six shillings
a week, and afterwards seven, to subsist on, he contrived to buy
rudimentary books and then classical writers, and the
benefit of his apprenticeship had accomplished his purpose.
He then determined to learn the Greek, and this he also
accomplished. The Hebrew, Chaldaic, and Syriac languages
were next mastered. When in his twenty-fifth year he
removed to London, he engaged in the part of his
employers repairing of a house, in which however
a fire broke out, when he lost all his tools, and was reduced
to extreme poverty. In the meantime the Rev. Archdeacon
Corbett had heard of his studies and abilities, saw him at Longnor,
left him a legacy of 100L, and appointed him in promotion.
In the course of a few months he acquired the Arabic and Persian
languages, and afterwards a tolerable knowledge of French,
German, and Italian. For two or three years previously to
1813 Mr. Lee held the mastership of Bowdener's foundation
school in Shrewsbury. In 1813 he left Shrewsbury, and
obtained an engagement with the Church Missionary Society.
In the same year he entered himself of Queen's College,
Cambridge, and in 1817 took his degree of B.A. Having
received one of the scholarships of the University, he was admitted
at Shrewsbury a sermon in aid of the funds of the Shropshire
Auxiliary Bible Society.

On the 11th of March 1819 Mr. Lee was elected Arabic
Professor of the University of Cambridge, but not having
been at College the time requisite for taking that degree
of M.A. (which was necessary before he took the chair), a grace
was passed the senate to request the Prince-Regent to grant a
mandamus, which was obtained accordingly. In 1828 the
degree of M.A. was conferred upon him. He obtained the
degree of D.D. In 1833 he was appointed chaplain to the
jail at Cambridge, and in 1835 was presented to the
rectory of Bilton with Horrowgate. He took the degree of
D.D. in 1837, and in 1831 he elected Regius Professor of
Hebrew to the University of Cambridge, and with that
accompanied canonry in the cathedral of Bristol.
The degree of D.D. was conferred upon him by
the University of Cambridge in 1833. He was afterwards presented to the
rectory of Barley in Hertfordshire. He died on the 16th of
December, 1853, at Barley rectory. He was twice married.

Among the more important of Dr. Lee's works are the
following:- Hebrew Grammar,' 1830; 'Travels of Ibn
Batuta, translated from the Arabic,' 1853; 'The Book of
Krain, translated from the Chaldaico, and English Lexicon,' 1840; 'An Inquiry into
the Nature, Progress, and End of Prophecy, Svo, Cambridge,
1849; 'The Events and Times of the Visions of Daniel and
St. John,' London, 1850; 'The Hermit's Tale,' a poem; in 1796 'Almeida, Queen of
Granada,' a tragedy, which was successfully performed, Mrs.
Siddons sustaining the principal character. In 1806 it
was published in six volumes, a novel entitled 'The Life of a
Lover,' which is said to have been her earliest production, and the
effort of her girlish years, and is certainly one of the
weakest of her writings. Her last work was a comedy, performed
at Drury Lane Theatre in 1804, called 'Asignation,' which
was condemned on the first night, and was never published.
Her chief of her poems is 'The Canterbury Tales,' of which she
furnished two, 'The Young Lady's Tale,' and 'The Clergyman's Tale,' which
occupy a volume and a half of the five volumes to which the series
extended; and she wrote the introduction to the whole.
These tales are certainly superior to her novels, but they are not
equal on the whole to those of her sister.

Harriet's first appearance as an author was in 1786, when
'The Errors of Innocence,' a novel in five volumes, was
published; this work was continued on the part of her
Peage; or, Our Eyes may deceave us,' 'Clara Lennox,' a
novel in two volumes, in 1797, and 'The Mysterious
Marriage, or the Heirship of Rosalia,' a play, in 1798; all
have been forgotten. The Canterbury Tales included
successive volumes, the first in 1797, the fifth and last in
1806; they were so immediately popular that second edition of the
first two volumes were published in 1799. They consist
of twelve tales, of which one, 'The German Tale—
Krutznitze,' furnished Lord Byron with the idea of
"Z"
the materials for his tragedy of 'Werner,' and he says of the tale that he had formed a 'high estimate of the singular power of mind and conception which it develops.' It is universally admitted that his lines are full of beauty and imagination, and that the work contains the most definitely drawn characters, and a well-developed plot. Several of the other tales however show a considerable knowledge of the human mind, are unexceptionable in their genre, pleasingly, and are narrated in a simple and unaffected style.

LEERSIA, a genus of Grasses belonging to the tribe 

Oryeae. It has 2 paleae compressed, keeled, and awnless, the lower one much broader; stigmas protruding from the side of the fruit, in the manner of the genus anemone, the plant is:

I. oryzaeetides has a patent paniere with wavy branches, spikelets triandrous, half oval, ciliated on the back. It is a creeping stem with a spine one to two feet high, never procur- blement, and rooting at the joints. The leaves are broad and rather firm, the 3rd horizontal one, the 4th verting a straw- reason; panicle rarely, if ever, protruded in this country, mostly inclosed in the sheath of the uppermost leaf. It is found in marsh ditches in Sussex and Hampshire.

LEFWARD ISLANDS. The British Leeward Islands, in the West Indies, form a distinct government, which includes the islands of Antigua, St. Christopher's, Anguilla, Montser- ret, the Virgin Islands, Nevis, and Dominica.

LEIGH. [Lancashire.]

LEIXLIP, county of Kildare, Ireland, a small town finely situated at the junction of the Rye with the Liffey, 11 miles W. from Dublin, by road and railway from Dublin to Galway; population, 332. It consists of a single street. The parish cloth has given a note of Gothic style, and has a chapel. The Liffey is here crossed by a bridge. Above the town is Leixlip castle, built by Adam de Hereford, one of Strongbow's followers. A little way beyond the castle the Liffey forms a fine cascade, called the Salmon Leap. The town is a place of resort on account of the beau- tiful scenery near it. Fairs are held in May, July, and October.

LEK, JOHN, architectural engraver, was born in 1784, in Sun-street, Bishopsgate, London, where his father was a manufacturer of pewter; and to him the youth was in the first instance apprenticed, but disliking the business, he was at the age of seventeen transferred as a pupil to Mr. James Basire, an eminent architectural engraver, and remained with him four years. Le Keux formed himself, how- ever, a true and bolder style than that of his master, and eventually in the engraving of gothic architecture attained an excellence equalled by few in the profession. Indeed, it would be difficult to say that his gothic architecture was for the first time thoroughly well engraved in this country by him; and that his engravings did much to render the study of gothic architecture popular. He possessed a very consid- erable acquaintance with both the general principles and the details of gothic architecture, and his engravings displayed, not only minute correctness, but that 'feeling,' as artists term it, which is always an evidence that the work is executed as a matter of enjoyment, and not merely as a task. Le Keux was in fact an artist and not a mechanic, and even the admirable architectural drawings of MacKenzie lost nothing in fidelity, and sometimes, perhaps, gained a little in spirit, under the rendering of Le Keux's burin. The first important work we believe on which Le Keux was engaged was 'Britton's Architectural Antiquities of England,' and he also engraved much of 'Britton's Cathed- ral Antiquities,' and other of Mr. Britton's works; the elder Puin's 'Architectural Antiquities of Normandy,' 'Gothic Specimens,' and 'Gothic Specimens of Westminster Abbey,' and 'Churches' (vol. I.); 'The Oxford Antiquities,' and lately the 'Memorials of Oxford,' and 'Memorials of Cambridge,' both of which were projected by himself and executed with much elegance, though of course from their smaller scale, as well as length, less freedom than his larger works. Mr. Le Keux died April 2, 1846. His eldest son, J. H. Le Keux, has a high reputation as an architectural engraver.

LEO. [Lym.]

LEONHARDITE. [Mineralogy, &c.]

LEPIDOGASTER, a genus of fishes belonging to the Subbrachial Malacopterygii, and to the family Cycloptorida, or Discopoda. [L.]

This genus of fish is distinguished by its smooth body without scales; dorsal and anal fins opposite and near the tail; pectoral fins large, descending to the inferior surface of the body, and by an extension of the membrane surrounding an oval disc; ventral disc contains a single opening, which is large, situated in the belly, and extends obliquely to the sides, at the anterior end of the oval disc. This fish is occasionally taken on the coasts of Antrim and Clare in Ireland. This fish is small, a specimen described by Mr. Conch not being more than two inches and a half in length. It adheres with its snacker to almost any substance presented to it, and is a most troublesome animal to the Angler. The individual fish is a pale flesh-colour, with spots and patches of carmine about the upper and under surface of the jaws, around the eyes, on the top of the head, sides of the body, and abdomen.

LEPIGONATUS, the Bimaculated Sucker, is a seced British species. This fish is rarer than the last. It has been taken on the southern coasts of Great Britain. It seldom exceeds three-quarters of an inch in length. Its general colour is a tawny red, pale flesh-colour underneath, with a light-coloured patch between the eyes, and sometimes inclined to some variation in the markings: the two spots on the sides not always very obvious. It lives in deeper water than the last species.

LEPILODICTYON, a genus of plants belonging to the family Cy- cladaceae. It is closely related to the genus *Monora*, to which the Common Cob belongs. The substrata are united with the nasal bone, and form a depressed muscle, advancing before the mouth, which however retains its mobility, and is crossed by small blood vessels. The ear- rinals are a little on the throat; the pectoral of most size; the first dorsal high; the second dorsal, anal, and cardinal united; the jaws short; the teeth fine and short. The fish is sometimes met with in the sea, and utters grumbling noise when taken out of the water. Two species are known. They inhabit the Mediterranean and Atlantic.

LEPIDODENDRON. [S.]

LEPIDOPTERA. The order of small insects, which includes the Lepidoptera, or butterfly insects.
3. The two preceding considerations are secondary to the remaining one—the nature of the contents of the cones. There may be stamens or male organs—ovaria or female ones—or, lastly, capsules containing reproductive spores (which are peculiar to plants having no sexual system). For these three kinds of spores all occur arranged in the form of cones, indistinguishable from one another by any external marks. Up to the present time no carboniferous fossil cone has ever been known to supply this great desideratum, without which we cannot reach the most conclusive assertion as to whether these curious objects are clusters of flowers or fruits, or are the spore-bearing organs of flowerless vegetables, as mentioned above.

Specimens of Lepidodendron are mostly found in seams of nodules of clay-iron-stone, and are very highly mineralised, sometimes containing crystals of iron, and the cavities in their substance being filled with white carbonate of lime and magnesia. Those which are most complete always form the nuclei to nodules of clay-iron-stone; others again, including all in which the spores are preserved, have occurred as broken frustules within stems of Lepidodendra elegans and other species of that genus. Usually the fragments of Lepidodendron are not more than half an inch long, and very frequently are mere cones, or stems arranged in these ways. In some instances, one or two fragments of the fragment of Lepidodendron, it will generally be found that this is owing to two being placed each at an extremity of the truncheon, and opposite to one another. [See Figure, page 482.] On the other hand, it cannot be doubted, for no modern cone of any natural order could be broken up into the shallow discus which many of these fossils present. It is difficult to account for the presence of these fragments of Lepidodendron in the stems of Lepidodendron; we must therefore conclude that these stems, whose interior was hollowed out by decay—that these stems were covered with water in which were fragments of Lepidodendron and other vegetable matter, which were introduced into the stumps. This supposition is founded on the following considerations—

1. The stumps of Lepidodendron appear to have been rooted and erect, and to have received the cone fragments into their cavity as fern fronds find their way into the axis of Sigillaria. Where the stumps were prismatic portions of stems it is evident that cones would have lain horizontally in them, and that no washing or drifting could have induced the fragments of these cones to lie with their axes parallel to them, or could have introduced so many into one stump; and the latter notion cannot have been materially conveyed had they received on one side the pressure of the impermeable schistose mud.

2. The stumps must have been submerged, and the fragments of the stumps lying submerged may be in due manner brought to be washed off into the stumps. This supposition is confirmed by the non-interference of the cones, and their uniformly vertical position with respect to the Lepidodendron.

It is hard to account for the accession of so large a volume of water as would submerge these stumps and deposit these fragments, and yet exhibit no signs of drifting in its course. The sudden fall of a tropical torrent of rain on a Lepidodendron forest, in which were hollow stumps of these trees, must have been a great event, of which the fragments of the Lepidodendron from the trees and float up the fragments on the ground, depositing them together in the stumps. Another effect of such a fall would be to break down some of the older trees whose decaying stumps would be prepared to inclose other Lepidodendron on the precipitation of the next similar torrent.

The extreme fragility of the Lepidodendron displayed by these specimens is very satisfactory, as the Lepidodendrons, of which they are the fruit, do not partake of this character; the deposit, the composition and intimate union with the silt or mud which is the basis of the clay-ironstone in the one case, and the formation of a homogeneous bed of vegetable material, each in another. The extreme abundance of the fragments too suggests a most vigorous vegetation, for they must indeed have been profusely scattered to be deposited in such numbers within narrow cylinders into which no current appears to have been directed.

It is worthy of remark that no fern-leaves are contained in any of these Lepidodendron stems; and their absence is not more striking than is that of these being commonly deposited along with branches of Calamites, &c., in the erect stumps of Sigillaria resting on the coal-shales. This is no doubt connected with the well-known fact of the Sigillaria stumps being filled with sandstone, or the same which are the tints; in the stumps the stumps, or other plants to the same spot. The perfect preservation in which these fragments occur must be attributed to the protection afforded them by the surrounding Lepidodendron bark. That the circumstance of the latter has been subjected to pressure may be inferred from the flattening of the prominences to which the leaves were attached. This pressure was moreover very considerable, as may be proved by comparing the evenness of their surface with that of a piece of earth containing a fossilised without preservation, and imbedded within the stem along with the Lepidodendron.

If these cones be examined with reference to the known contemporaneous fossils which accompany them, it will appear impossible to deny their having the reproductive organs of modern conifers. There is no resemblance whatever to the cones of Lepidodendron, Lepidodendron and other species of that genus, because the arrangement of the tissue in the axis of the cone entirely agrees with that of the stem of Lepidodendron. Just as we find in modern cones of Lepidodendron and other species that the axis is a continuation of the trunk, of which it is the interior portion, and its organs adapted to support and protect the parts of fructification. The most positive evidence that can be adduced of Lepidodendron belonging to a genus allied to Lycopodium is afforded by the spore, the presence of which is another, as may be inferred from the existence of the spores and of the affinities of the plants which produced them. Accordingly we find that Dr. Lindley, the first English observer who published any extended views on the affinities of these plants, suggests the probability of their being referred to a genus without spores, or at most very probable still to Cycadea. Dr. Hooker, after describing the nature of sporious cones which have no relation to the reproductive organs of the plant, as in the common cone-bearing willow, or the beech (as a proof of the nature of some), and the various cones of Lepidodendron and other species of this order, it is impossible to say that the cone of Lepidodendron is formed without an imbrication of its parts, as in a genus inhabiting Tierra del Fuego, where a cone is formed by this means from a leaf, says:—"Some of the so-called Lepidodendron may be of this nature: witness the Lepidodendron obelia, of which it is impossible to say whether it is formed from leaves or cones."

L. incurratus has a cylindrical subulate spike; 2 glumes equalling or slightly longer than the flowers; stem from 5 to 6 inches long; spike long, covered with a rich variety of this species, L. fitiformis, the spikes are much more slender, filiform, scarcely at all curved. It grows in sandy salt-marshes.

LENN H. [Botanical Cyclopedia.] The following by Dr. Baird, an examination of the British species of the Lenzend, or Lennards:—

Tribe I.—Anchorastomateae.

Females.—Attached to their prey by means of their foot-jaws, which are stout and armed with strong hooks. One pair of antennae; generally very distinct. Thoracic feet 2 2 Z
nearly rudimentary, or represented by appendages of considerable size, but differing in form from ordinary feet.

Males.—Free and unattached; very small, and differing totally in appearance from the females.

Family Chondracanthidae.

Organs representing thoracic feet, in form of considerable-sized, cartilaginous-looking, not articulated appendages; generally three pairs in number. Three pairs of foot-jaws.

Genus 1.—Chondracanthus.

Two pairs of foot-jaws prehensile, the third nearly rudimentary. Appendages of thorax representing the feet, in form of large digitations, but not articulated, and not setiferous lobes or tubercles. Oviferous tubes very short, broad, and flattened.

C. Zei. Body short, and rather thick. Head rounded; antenna short, and rather broad; neck narrow, short. The thorax carries on the underside two pairs of small appendages, each consisting of three divisions or fingers, and furnished laterally with three pairs of longer prolongations, of many divisions, the terminal one on each side larger than the other. Thorax conical, divided into five segments, part of the thorax is covered with short, conical, sharp-pointed spines. Abdomen rudimentary. Oviferous sacs flattened, containing many small ova.

It is found adhering to the gills of the Zeus faber.

Genus 2.—Lernentoma.

Foot-jaws and thoracic appendages as in Chondracanthus. Oviferous tubes long, either club-shaped and stout or slender and twisting.

1. L. cornuta. Female.—Head oval, rather elongated; antenna flattened, of considerable size, and projecting. Thorax elongated, club-shaped; anterior portion narrow for about a third of its length, the other two-thirds much broader, and terminating posteriorly in two sharp lateral tubercles, of moderate length, and a third one representing the abdomen, which is nearly quite rudimentary. Two pairs only of thoracic appendages are visible, occurring at the upper portion of the narrow part, each divided into two digitations, and situated at a short distance from each other. The ovaries situated on the sides, cylindrical, and about two-thirds the length of the body. Length nearly 3 lines.

Male.—Somewhat pyriform in shape. Head very large, swollen, and projecting from the touch, representing the thorax, and terminated by a rudimentary abdomen armed with two small hooks. Antenna slender, setaceous, projecting from the anterior extremity of the head, and underneath them a pair of hook-shaped foot-jaws. Mouth situated far back, and provided with mandibles, which is behind the mouth two other pairs of foot-jaws are visible. Following these we observe two pairs of setiferous tubercles representing the feet. Length, a quarter of a line.

It is found in the form of a sole.

2. L. costata. Female.—Body somewhat square-shaped. Head small, and situated at the end of a long and slender neck; it is rounded at the anterior extremity, and a little below the antenna exhibits on each side a round lobe or tubercle. The antenna and foot-jaws are very small. The neck nearly equals in length the rest of the body. The thorax is broad, and of a somewhat quadrangular shape, with a deep indentation on each side about the middle of its length. On the upper half we see two pairs of prolongations or ctenidial tubes, divided into three digitations, and on the lower half there are three smaller appendages, bastiate, not digitated. The posterior angles of the thorax are prolonged also into short horns or appendages, which are also simple. The abdomen is in form of a short tubercle, with a rounded posterior point. The oviferous sacs are of about the length of the whole animal, of considerable size, and cylindrical.

The male is similar, according to Milne-Edwards, to that of Chondracanthus (Lernentoma) cornuta.

It is found attached to the caudal spine of the Triplet.

3. L. longipapillata. Female.—Body rather elongate, and somewhat gibbons. Head small, having on each side a small horn-shaped appendage directed a little obliquely backwards. Antenna small, conical, and slightly curved. Thorax divided into four portions by as many contractions. The first narrow like a neck, having, on the upper portion a short spine, and on the under surface a pair of appendages or prolongations of two divisions or digitations; the second is somewhat quadrilateral, with on the middle line of the back two conical tubercles and on the sides two others, the upper pair of the longest, having on the under surface a pair of appendages of two digitations; the third part is larger than the preceding, and has the same tubercles and prolongations, and in addition a small spine on the superior portion, and in the mesial line of the under surface; the fourth portion is rather the largest, with two horns or tubercles on the upper surface, a third on the median line of the under surface, and on each side a long terminal prolongation, rather blunt. Abdomen in form of a short tubercle in the centre of the posterior angle, and bearing two pairs of foot-jaws of slender, and twisted. Length, 65 lines; breadth 23 lines.

The male is very similar to that of the Chondracanthus cornutus already described.

It is found on the Lophius piscatorius, in the poncho.

Tribe II.—Anchoracanthaceae.

Attached to their prey by means of two long appendages which arise from the thorax. They unite together either at the base or near the tip. Only one terminus in a round knob like a button, by means of which the animal maintains its hold of the part to which it has attached itself.

No thoracic feet, or they are represented by these arm-shaped appendages.

Many are slightly differ very much in appearance from the females, being greatly smaller and unattached.

Family 1.—Lernopodidae.

Arm-shaped appendages long, wide apart from each other at their base, and united only at the tip.

Genus Lernopoda.

Female.—Body generally elongated, oval. Head short and thick. Two pairs of foot-jaws, well-developed, are placed near each other. External ovaries of moderate length and cylindrical.

Male.—Body divided into two nearly equal portions of an ovoid shape; one representing the head, the other the thorax.

Much smaller than the female.

1. L. elongata. The head is very distinct, of a hairy texture, ovate, depressed, broad at the base, and obsolescent, present in form, resembling very much the shape of the body of the common Spider-Crab. The second pair of foot-jaws is large and well developed, consisting of a large rounded oval basal joint, and a more slender curved hooked terminal one, with a pretty strong tooth on its inner edge. The head is united to the body by a short narrow neck; the thorax is divided, forming a somewhat small hook. From the thorax we give origin to two long cylindrical arms, which considerably exceed the length of the body. At the posterior portion, which is somewhat truncate, we see two small lobes; and on each side of these springs the ovaries, which are about the length of the end of the head, thick, straight, and cylindrical.

Length of the whole animal nearly 3 inches. Head, one line and three-quarters. Body, 74 lines. Arses, one inch and one line and a half. Ovaries, one inch and one line and a half.

A specimen of this arctic species was found attached to the eye of a shark caught on the coast of England, and brought to London in the winter of 1848.

2. L. galei. Female.—The head is oval, depressed, and of a hard horny substance; the thorax is long, rather slender, and somewhat cylindrical, narrow where it is attached to the head, and broader, and more obtuse posteriorly. The arms are slender, and nearly the length of the thorax. At the posterior extremity of the body are two small lobes, between which, on the middle line, is a small tubercle representing the abdomen. Ovarian tubes of moderate length, not quite equal to the length of the thorax.

Length of the whole body, including arms, about three-fourths of an inch.

Male.—Body divided into two portions, of an oval form, and nearly of equal size; the upper half represents the head, and being united to the body representing the thorax, arms, and pair of antenna, and bears on the sides of foot-jaws of much considerable magnitude; the lower half, representing the thorax, has at its posterior extremity two sub-globular appendages a little longer than those in the female.

Mr. Ham was found attached to the cavity posteriorly to the vent of the Squilla galea.

3. L. Salmonis. Linnaeus's description of this species, as
far as it goes, is very good — "Body ovate; thorax obcordate; the two arms linear, approximated." The head is rather small, somewhat longging out at the back part, broader there, and rather sharp pointed at the anterior extremity. From the base of the head spring the two arms, which are rounded, and slightly shorter than the body. The thorax is pyriform and short, and at its base there are two minute eminences. The ovary tubes are of considerable thickness, cylindrical, and about the same length as the whole animal.

The colour of the animal is white. Length about half an inch.

It is found in the gills of the Salmon, in the London markets.

Family II. — Anchorellaeidae.

Arm-shaped appendages very short, and united to each other from the base, so as to resemble a single organ.

Genus Anchorella.

Female. — Body in general short, and somewhat swollen. Head small, and situated at the extremity of a long neck, which is generally curved backwards. Two pairs of foot-jaws well developed, and a third rudimentary. Antennae rudimentary. Ovarian tubes of moderate length, and cylindrical.

The female differs in appearance very much from the female, and is very small.

1. A. uncinita. Female. — The body of the animal is thick, olbong, of a milk-white colour, smooth, and opaque. Head very small, situated at the extremity of a long slender neck, which has a wrinkled appearance, and is nearly the length of the thorax. The arms spring from the upper part of the thorax, and are rather short, terminating in a rounded knob or button. At the posterior portion of the thorax there is on the middle line a small protuberance representing the abdomen. The ovarian tubes are cylindrical, straight, smooth, and about the length of the body. Length from 6 to 8 lines.

Male. — Body globular, terminated in front by a small conical eminence, at the extremity of which is the mouth, and having at its base one pair rudimentary appendages, and a pair of rudimentary foot-jaws. On the middle of the body, on the inferior surface, there are two pairs of large book-d-claw-like members. Length, one-fourth of a line.

The female fixes itself to the fins and gill-cover of the Cod and Haddock, and is most probably the most common species of our seas. (Johnston.)

2. A. rugosa. Body nearly of a square shape, a little emarginated on each side. Head small; neck slender, and nearly cylindrical. A rounded tubercle on the middle line represents the abdomen. Ovaries rather larger than the thorax, nearly cylindrical, or slightly club-shaped. Length, about 3 lines.

Found in the mouth of the Gadus callarias.

Tries III. — Anchorellaconi.

Females. — Attached to their prey by the anterior extremity of their body only, thrusting the entire head into the tissues of the animal to which they adhere, and being retained there by means of a kind of horns, which are various in form, and spring from the posterior part of the head. No antennae. Only one pair of foot-jaws, which is simple and hooked. Feet either very small or often wanting altogether.

Males. — Very small. Body globular, and more imperfect than in the preceding tribes, having no distinct thorax, and no rudiments of feet behind the appendages which represent the foot-jaws.

Family I. — Peniidae.

Several pairs of feet situated on the under surface of the body near the head, but very small and rudimentary.

Genus Lernocera.

Body long, slender, narrowed anteriorly in the form of a neck, which is terminated by a swollen head furnished with two or three simple curved horn-shaped appendages. Abdominal portion of the body of considerable length, and simple. Oviferous tubes long and slender.

1. L. sprupta, the Eye-Sucker. Body slender, considerably larger than the ovaries. A pair of tolerable size, rounded, and provided with two narrow rather hooked horns at its back part, directed backwards. The head is connected to the body by means of a long and very slender cylindrical neck, which is furnished with about a dozen constrictions, each of which makes the part of the body appear as if it were beset with an equal number of rings or knobs.

A short distance beneath the head it is very narrow, gradually increasing in size as it joins the body. Abdominal appendages are of a yellowish hue, and obliquely truncate. The ovary tubes are very long and slender, about as long again as the whole body of the animal. Length of the body about an inch; ovaries one inch and a half.

It is found attached to the eyes of Sprats.

2. L. artificialis. Body cylindrical, shorter than the preceding, and about the same size at both extremities. The neck is long and slender, quite smooth, and destitute of the constrictions which mark so decidedly the preceding species. The neck is white, and the body is of a brown handy colour.

The abdomen is like that of the preceding, and the ovarian tubes are long and slender, at least twice the length of the body. Turton describes the ovaries as "clear white." Perhaps they may be so in the living animal, but in the specimens preserved in spirits they are of exactly the same colour as the body. In one specimen however one of the tubes is broken, and the ova have escaped, and in this the tube is white. Length of the body about half an inch; ovaries fully one inch in length.

It is found attached to the bodies of the Chapea encrasico- lus and C. spraptus.

Family II. — Lernoceradea.

No vestiges of feet on under surface of body, nor any appendages representing them.

Genus 1. — Lernocera.

Body long and slender; head furnished with horn-shaped appendages, which are simple and symmetrical in form. Ovarian tubes straight, and of moderate length. Abdomen very small.

L. opirinac. Head furnished with four horn-shaped appendages, which are somewhat long and slender. The two outer or posterior are bifurcated; the anterior simple.

The thorax is very slender anteriorly, forming a long neck, but becomes much broader posteriorly, and when it terminates in the small abdomen appears obliquely truncate. The oviferous tubes are cylindrical, and rather long. The length of the whole animal is about 8 lines.

It is found on the sides of the Carp, Bream, and Roach, in many of our ponds and rivers, in great abundance.

Genus 2. — Lernes.

Body more or less twisted, and out of appearance. Head furnished with horn-shaped appendages, which are irregularly branched. Ovarian tubes twisted into round masses, and placed under the posterior portion of the body. Abdomen of considerable size.

The genus Lernes is now restricted within very small limits. Established by Linnaeus upon the L. branchiata, it is at the present day confined to that species and one or two others.

L. branchiata. Head rounded, and furnished with three horn-shaped appendages, each of which is divided at the tip into three short branches.

The anterior portion of the thorax is long, cylindrical, and very slender, like a long narrow neck, while the body itself is very much swollen in the middle, and abruptly twisted upon itself in the form of the letter S.

The abdomen is very long, blunt at the extremity, and of considerable size. The oviferous tubes are slender and very much twisted.

The whole animal is about an inch and a half in length, and is of a very firm consistence, being hard and horny.

It is found on the gills of the Cod. ( Baird, History of British Entomatares; Milne-Edwards, Histoire Naturelle des Crustacés.)
S58 was 1861. The Olen-Swilly at a and 23°.
The scene of Glen-Swilly above Letterkenny, and of Long Swilly, the best pictorial area of Glen-Swilly, has declared itself an independent state, and carried in the affirmative.
A convention was then appointed to draw up a constitution, and on the 24th of August, 1847, the flag of the Independent Republic of Liberia was raised in ceremony.
The chief events in the history of the settlement have been the numerous encounters with the natives, and since its independence the visits of the president to England and America with a view to the arranging of certain treaties. The republic was recognised by England as an independent state soon after its declaration of indipendence, and has since been recognised by France, Prussia, Brazil, and some other powers, but not by the United States.

The coast of Liberia has a general direction north-west and south-east, and is broken by several bays and coves of which those formed by Cape Mount, Cape Mesurado, and Bassa Cove are of much value as harbours. The greatest part of the coast is low and sandy, or marshy; but about Cape Mesurado the coast becomes more elevated, and eastward the shore is considerably elevated. Between these points however there is a low continuous beach of light brown sand, backed by an unbroken tract of forest. Towards the south-eastern extremity the coast is in many parts b-hl and rocky, and the cliffs in many places are broken into a large part of the sea, with large irregular blocks of granite on the beach, over which the sea breaks heavily, and many rocks lie a short distance off the shore; but between the higher parts everywhere occur long stretches of low sandy beach, in many places bordered by sand-banks; and so near as a large coast it is necessary for the mariner to keep a sharp lookout.

From the coast the land rises for the most part gradually towards the interior. About 20 or 30 miles from the shore is a succession of hills covered with a dense undergrowth, and the rest of the lower country, with forests, rising farther inland into mountain ridges, and divided by wide and fertile valleys. The river is numerous, and some of them are good-sized streams; but all have their mouths obstructed, and some entirely closed, by sand banks, and are only navigable by canoes; some of them appear to be navigable far inland. The chief river is the St. Paul, which falls into the sea by Cape Mesurado. The sand-banks at its mouth leave only a narrow channel for boats within a few feet of water at it low tide. It is about 40 miles in length, while wide 40 or 50 feet, and in some of its mouths its body of water, flows through an extremely fertile valley, and has along its banks numerous native villages as well as settlements of the Liberians; but its course is greatly obstructed by rapids; boats of light draught can only ascend it for about 25 miles. The other most important streams are the St. John, which falls into the sea at Bassa Cove; the Jab, which lies between the St. Paul and St. John, and has a very narrow channel through the bar at its mouth; the Cape Mesurado, which is obstructed, and the Dolo, which has its entrance almost closed by a narrow spit of sand; the Grand Cessos, some distance eastward; and the Dolo, still farther east, which has about 6 feet of water over its bar, descending inside to 4 or 5 feet.

The climate is hot and oppressive. During the dry season, which lasts from May to November, the temperature averages 85°; but in the wet season it falls to 75° or 74°. The extreme heat is alleviated by gentle breezes, which blow daily from the sea. Should the barometer fall too low for comfort, the American climate is very prejudicial; but the negro colonists, though the descendants of families long settled in America, have experienced no inconvenience from it after they have passed through the seasoning, or acclimatization for which they have been exposed. They are comparatively seldom fatal in its attacks. Nothing like an epidemic has ever appeared in Liberia.

The following brief extract from an Address of the
The colonists have erected a lighthouse on Cape Palms, which shows a fixed light 100 feet above the sea. There are two or three villages at the mouth of the river.

The constitution, adopted at the declaration of the independence of Liberia, and said to have been drawn up by Professor Greenleaf, of Harvard College, Massachusetts, is founded on that of the United States, which it greatly resembles in political arrangements. It is independent of all men; establishes perfect religious freedom, and the liberty of the press; prohibits slavery; gives the right of every one to be tried by a jury of his peers, of bail, and of habeas corpus; makes no all offices elective, and gives the suffrage to every male above 21 years of age. Its capital is a grant of five acres of land, with liberty to purchase more. The executive government is vested in a senate elected from the counties, and a house of representatives elected after the American system, according to a ratio of representative population; and a president pro tempore elected for two years, is to exercise supreme executive power, is the commander-in-chief of the army and navy, and has a qualified veto on the acts of the legislature. The judicature consists of a supreme court, chief-justice, and district judges, appointed by the president on a vote of two-thirds of the houses of legislature. The annual revenue and expenditure average about 7000£ a year each. The republic appears to be making steady progress.

Liberia is divided into the counties of Monrovia, or Montserrat, Bassa, and Sinoe. The chief town is Monrovia, or Montserrat, which took up his situation at the mouth of the river, as the principal place of trade. It contains a court-house, a public library, two or three churches and schools; several stores, warehouses, and good wharves; a fort and a lighthouse; and has about 1800 inhabitants. The other larger towns lie on the banks of the river, Monrovia being at the mouth, and on the right bank of the Junk River; Edina and Great Bassa at the mouth, but on the opposite banks of the St. John, in Bassa Cove; Bexley, and the new town of Cressen on the same neighborhood; Greenville on the Sinoe; Trade Town, a populous place 4 miles W. from Youngest; and Cestos, or St. George's Point in Cestos Bay. The chief inland towns and settlements are Caldwell on the St. Paul; New Georgia, and Millburg. Along the coast are several factories, chiefly for the trade in camwood, belonging to Libarians, and some to English and American merchants; and both along the coast and inland are numerous native towns and villages, some of them, as Grand Cestos and Great Neeboo, of considerable size.

On Cape Palms, the south-eastern extremity of Liberia, is established the colony of Maryland-in-Liberia, consisting of free-coloured emigrants sent thither from the state of Maryland by the State Colonisation Society. The colony was settled in 1834, and a tolerable number of free-coloured persons have since been sent to it by the Society, which is assisted in its operations by an annual grant from the state legislature of 20,000 dollars. The colony, which is independent of Liberia, is governed by an agent, or govern- nor, and his council; a major-general, a council and other officers elected by the colonists; and appears to be in a tolerably flourishing condition. Harper, the chief town, contains about 700 inhabitants, and carries on a good deal of trade. The Palmas River is about a hundred yards wide towards its mouth, but several rocks lie in the channel; it has a depth of 3 feet over the bar at low water.
with England, into a grievous mistake. It is only too true that there are more books in Paris than in London, but this is a matter of proportion to the number of inhabitants

360

— LIB

— LIB

of the two cities; in Paris, estimated at between twelve and fourteen thousand inhabitants, and in London, between eighty and eighty-five thousand. But it is not true that there are more books in Russia and Hungary, in Portugal and Spain, in the United States of North America, than in Holland and England. It is not even true that there are more books available to the working classes in any of the countries named than in England. There are coffee-houses in the by-streets of London which have larger libraries than can be found in the cities of from five to ten

and fifteen thousand inhabitants in Germany or Denmark. There are divans in the Strand where more papers and reviews are taken in than in the Casino of Prato. In fact, with the exception of the United States of North America, no nation in the world has so many books, so much literature, in proportion to the amount of the population, as England. In Spain, in Italy, and Germany, even in France, very few persons have private libraries in their own houses. In England a house is not considered furnished without a stock of books. Even the cottage of the peasant has its family Bible, and its copy of Shakespeare or Milton, a thing having no parallel in some of the countries standing higher in the above list. It is ill supplied by foreigners, they in England are of no pictures. It is much the same with regard to books. But the fact is, both our art and our literature are gathered up in our houses; while in public collections we are lamentably deficient, but only in public collections.

As a nation, as a community, in small quantities, and in many houses, it has its evils as well as its virtues. It induces a certain amount of reading in the classes to whom literature is chiefly a graceful recreation; but the education of the classes into which literature is not to a sufficient extent, so far as I could gather from the records of letters, is the case in France, how the number of letters, surnamed by the most deplorably. Within the reach of men of letters, living there was no library in London, accessible to the public, even moderately complete in the great departments of inquiry. Gibson had to purchase all the books necessary for the composition of his great works. Fortunately for us he had the means. Roscoe was unable to obtain from any public library in Liverpool the ordinary Italian authors whom he had to consult on the subject of his biographies. Still later, the historian of North America (Graham) found himself obliged to remove from London to Göttingen, in order to get access to a wellstored library, which was at the same time open to the public. Within a year or two of our own time, Robert Southey was obliged to collect at his own cost all the materials of his voluminous writings, as any other author would have to do again next year, if we were inconvenient for him to reside in London, and to attend at the British Museum in the heart of the day. How disastrous is the scarcity of books, publicly accessible, upon the present topic of the number of letters is seen, in any example, let any of the reading rooms, day after day, of the British Museum and the National Library in Paris, he will at once perceive that two distinct classes of persons frequent these rooms. In London he will find only men of letters and artists, the teachers of the people. In Paris he will observe that it is the people themselves who come to read. In the British Museum he sees only grave men and women dressed in the customary suits of sober black, so well befitting the vocations of letters. In the National Library of France there are observed men from the civil and military college, soldiers of the guards, officers, clergymen, shopkeepers, porters, and generally speaking speaking semiclasses of all classes of the population. A deep sound of the over the shoulder of the readers in the two rooms will reveal another difference between them. In London, you see the tables covered with old volumes, maps, and manuscripts — the literature of the past. In Paris, you notice that the readers are chiefly poring over the new books and newspapers — the present. This, of course, is an absolute — Louis Blanc — the living literature of their own age. In Paris, there is only a library of reference; the Parisian institution is a library for reading.

In Paris there are 7 open Public Libraries.

In Brussels there are 2

In Berlin there are 2

In Milan there are 2

In London there are none.

Compared with the population of these cities thus provided — the whole of them little over-counting London alone — the facilities for mental culture afforded to our masses are not to be named. Indeed all the collections of books which can by any straining of the terms of their acts of foundation be considered as public libraries are wretchedly inadequate to meet the wants of a population pining for a higher class of reading matter. A man who feels this need has recourse to the British Museum — the library of Sion College, in London Wall, founded by Dr. White, in 1636, and now containing nearly 40,000 volumes; the library in Red Cross Street, founded by Dr. Williams, now containing 50,000 volumes; and Archbishop Tenison's library in Westminster, containing about 4000 volumes. This last is now degraded to the purposes of a club-room. These are all public libraries, a card of admission is obtained in much the same way as at the British Museum. Of course there are many more libraries in London to which men of letters obtain access for the objects of their craft as the library of the East India House in Leadenhall Street; the libraries of the Inns of Court; libraries connected with the various professional colleges; the library of Lambeth Palace; and so on. There is none of these can the books be borrowed. None of them are open to the general public, or to the unknown student. The only decent library in London from which books may be taken home is a subscription library in St. James's, whose catalogue is imperfect in all departments, and is moreover barricaded by a large entrance fee.

Out of London, the Bodleian at Oxford, and the University Library at Cambridge, are the best in England. But these are only to the learned class; and not only so, but to the majority of the students themselves. It is the same in the University Library in Glasgow. At Trinity College, Dublin, at the University Library of Aberdeen, and at that of St. Andrews, the same is the case. These are private libraries, and are not open to the public. Chetham's library, in Manchester, containing about 20,000 volumes, has the reputation of being the only one in England open to the public after the manner of the Conti-
west. In Dublin, there are four other decent libraries in addition of that of Trinity College—belonging respectively to the Royal Irish Academy, 10,000 volumes; to the Royal Dublin Society, 19,000 volumes; to the Queen's Inn, and Marsh's Library, 18,000 volumes. The Advocates' Library in Edinburgh is the chief public collection of books in the east of Scotland.

Besides these great collections, which are known but not easily accessible to the general public, there are a consider- able number of smaller libraries, scattered all over the country, which are not known nor accessible—but which may constitute the nuclei of a system of public libraries by and bye. These little- known collections consist of two kinds of libraries and parochial libraries. Of the former, there are known 34 in England and 6 in Ireland. For the most part they are stocked with works on theology and divinity, but some of them have also works on literature and history—particularly ecclesiastical history. Many of these have incomes settled upon them by pious and munificent found- ers. In such places, new books are added yearly; the number of volumes which they contain will average from 7000 to 10,000 in each. In some the books have had little care taken of them, but in others they are in fair condition for the public. Generally speaking, these church libraries are the closest of corporations. Parochial libraries once prevailed to a considerable extent throughout England and Wales, and Scotland; but now, through the rapid growth of the working classes, there are not less than 183 such institutions in England and Wales, and 16 in Scotland. These parish libraries were founded in the first instance by private benevolence. Many of them owed their origin to the efforts of Dr. Bray and his friends, the founders of the Clergy of the Established Church, at the beginning of the 18th century; but others had already been in existence some time, as we learn from the preamble to an Act of Parliament for their better preservation, passed in 1708. Many of these libraries, from sheer neglect, have fallen into a state of decay, and are in need of serious reform, at the beginning of the 19th century; but others had already been in existence some time, as we learn from the preamble to an Act of Parliament for their better preservation, passed in 1708. from the more intercourse of daily life at Thorn, where I was much neglected; and that if I were made professor I should myself be obliged to begin to learn the language anew from the first rudiments. In the course of 1792, however, Linde received the appointment, and began to do as he had said. Among the books that he procured from Poland as the Polis Poles of Paris, or Poles of Vienna, the satirical play, directed against the national failings of the Poles, which he found so excellent, that, though many passages were beyond his comprehension, he commenced a translation, with the intention of making it the original, or as a book for study with his pupils. I was lying on his table when two Polish gentlemen called on him, whose attention was at once attracted by the book, and he asked them if they could inform him who was the author of that unusual work. One of them, Niemieczwicz, replied, "I wrote it." "That moment," Linde afterwards said, "was the decisive moment of my life." Niemieczwicz became his intimate friend, explained to him the passages that had perplexed him, and introduced him to the society of the other distinguished Poles then living at Leipzig, to which it appears the professor had hitherto had no access. Among them were the Counts Potocki, Kellotaja, and Thaddæus Kociszewski, some of the most illustrious names of Poland at that period. The first had been driven from the lips of gentlemen and scholars, became fired with enthusiasm for the Polish language, and resolved to devote himself to the production of a great Polish dictionary. He took this resolution at the age of twenty-two; he published the last volume of it seven years later, after, as he wrote, he had worked at it almost unremittingly during the interval. The Dictionary of the Polish Language, 'Słownik Języka Polskiego,' occupies six quarto volumes, of which the first was published at Warsaw in 1807, and the last in 1831. It fills about five thousand quarto pages in closely printed double columns; to every word is appended an explanation in Polish and German, a comparison with the forms which resemble it in the other Slavonic dialects, and a collection of passages in which the word is used. The whole was read by Linde through six or seven hundred of the principal words in Polish, of which he gives a list in the first volume. It was the first great dictionary of the Polish language; it has served as the basis for every subsequent one, and, though of course susceptible of improvement and augmentations, it is not likely to be ever either superseded or surpassed. In the course of its preparation Linde soon resigned the professorship at Leipzig which had first given rise to it, passed some time at Warsaw, then became librarian to Count Osolinski at Vienna, and had the congenial employment of travelling in Poland to collect Polish books, by which he enriched the library and his Dictionary together, and lastly established himself in Warsaw, where he superintended the printing, which was carried on in his own house by a commissary with whom he had the privilege of immuniizing themselves by affixing their own names at the end. These labours were carried on during a stormy period, but the house in which the printing was conducted was not surrounded by.tending armies, and the author received support from the Russian and the Austrian governments, and in particular from the Russian, as well as from numerous Polish magistrates, one of whom, Count Zamoysky, when the works were on one occasion brought to a stand by an absolute want of pecuniary means, sold a favourite horse and sent the proceeds to the lexicographer. Linde held various appointments connected with the educational establishments of Poland, and was even first librarian of the University of Krakow, and resided at Warsaw as rector of the Lyceum and principal librarian of the university, during the long period of comparative tranquillity which preceded the insurrection of 1830; and though he was elected to the revolutionary diet as member for Praga, was avowed to that unfortunate movement, which he thought ill-timed and likely to issue in nothing but calamity. Fryxell the Swedish historian, who, in his travels in search of Swedish documents, was surprised to discover that Linde was the author of a history of his own countrymen, found him depressed and melancholy in the year 1834. "It was instructive," says Fryxell, in the preface to his 'Handlings rörande Scandinavien Historia,' "to hear him talk in the reasons of Poland's fall first and foremost in the national decay of the Schwedes themselves, and in instructive especially for a Swede, who belongs to a country which has the same powerful and wily neighbour that Poland had, and who bears the same misleading doctrines preached around him which ended in subjugating Poland to the Russian yoke." Linde at that time been re-appointed by the Russian government to some of the educational posts he formerly held; but he resigned them in 1838, and appears to have lived in retirement till his death on the 8th of August 1847 at Warsaw. In addition to his Dictionary he was the author of the 'Przygody Potockich,' a novel published in 1829, and the 'Polish Grammar,' which has been very generally adopted in Poland, and to whom he has been most familiar. The most important of those was his translation (Warsaw, 1829) of the Dissertation on Kolubeck, the old Polish historian, by his friend and patron Count Osolinski, who it should be mentioned assisted materially in the preparation of it, and to whom in conjunction with Prince Czartoryski, also a munificent patron, that work is dedicated.
southern Europe and Great Britain. It has linear glabrous leaves, corymbose heads, the involucral lacinia; the stem from 12 to 18 inches high, simple and leafy; leaves single ribbed, smooth or scarios, very numerous, more or less dotted; flowers yellow. It grows on limestone cliffs. It is the

LINTON. [Lancashire.]

LISTA Y ARAGON, ALBERTO, an eminent Spanish mathematician, was born at Seville, in 1776, on the 16th of October, the day which, as he delighted to remember, was also the birthday of his favorite poet Virgil. His parents were in humble circumstances, and engaged in silk-weaving, and in his early years taught the children in their family. When he was eleven years old, he displayed such talents for mathematics, that by the time he was thirteen he was already enabled to earn his own living by giving lessons to pupils. As he went about from one house to another for this purpose, he filled up the intervals by playing with the other boys in the streets. At fifteen he was made teacher of mathematics in the schools of the society of 'Amigos del Pais,' and at twenty nominated by the king to the same office in the nautical college of San Telmo at the seaport of Buenos Ayres. At the age of twenty, and being in Seville enthusiastic in their devotion to literature and intimate personal friends, Arjona, Reynoso, Lista, and Don Jose Maria Blanco, afterwards so well known in England by the name of Linton.

In 1808, soon after Lista's appointment to the professorship of poetry and rhetoric at the University of Seville, the French invasion brought ruin to every literary circle in the peninsula. Lista at first joined with Blanco in continuing the 'Censor,' but latterly there were four young men's papers that was composed also by Lista and his associate called 'El Censor,' one of the best periodicals of Spain has ever produced. In 1822 he published his poems, with a dedication to Blanco White, the name of 'Abino.' They at once placed their author among the first poets of modern Spain. Not long after his publication of a sort of private college at Madrid, the reputation of which was singularly high, and had the effect of exposing him to many annoyances on the part of the government. Among the pupils of Lista at different periods of his life are found the names of Duran, Mercado, and Jerez de la Vega, Rosas de Togores, and many others of peculiar eminence. He became dispirited by the obstacles thrown in his way by the authorities, that he finally left the country and established himself at Bayona in Spain, which supported him by its circulation in Spain till it was prohibited by the ministry. He then went to reside at Paris, and while there paid a visit of a fortnight to London, for the exclusive purpose of renewing his intercourse with his old friends. In 1820, he was minister of the Church of England, resident at Oxford. When the friends met their emotion was so great that both were for some time unable to speak. Soon after, in 1833, the writer whose 'Gaceta de España' he founded, and who brought out for the first time a daily newspaper in Spain, was unwilling to edit the 'Gaceta de Madrid,' by which his leading articles were so highly approved; that King Ferdinand offered him in recompense the bishopric of Astorga, which he declined in favour of his friend Torres Aguirre. He afterwards demonstrated the necessity of his life flowed through a series of honours. When in 1837 he resigned the editorship of the 'Gaceta,' he became professor of Mathematics at Madrid, and helped to establish the Athenaeum, or university there. His health suffered by the climate of Madrid, and he removed to Cadiz, where he superintended the new college of St. Philip Neri. In 1840 he gave this up, and returned to his native Seville, on his road to which he was met at two leagues off by a procession of friends with many honours. Torrellas, Eacogidos, Lista, and a collection of selected extracts, 'Trastornos Espafiola en Prosa y verso.' But the French invasion brought ruin to every literary circle in the peninsula. LOCHMABEN. [DUMFRIESSHIRE.]
LOCKER, EDWARD HAWKE, was the son of Admiral Locker, to whom Nelson, soon after the battle of the Nile, presented a New Year's gift. His friend, then in the New Year's gift acquainted, knew that a valuable service could be rendered to him in the acquisition of knowledge, that no useful book was to him, and that a valuable service could be rendered to him in the acquisition of knowledge, that no useful book was to be had. He had been educated at Eton, and had entered in the year 1756, and received an appointment in the Navy Pay Office. He remained in government offices till 1800, when he went to India as private secretary to Lord Elphinstone. From that time to the peace of 1814, he was associated with that distinguished commander in arduous and confidential duties, superintending the affairs of the major ports of the Mediterranean, and for his efficiency and able discharge, which discharged with eminent ability. In his official capacity he visited Napoleon at Elba in May 1814; of which visit he published an interesting narrative after the death of the Emperor. Mr. Locker married the daughter of an eminent antiquary and philologist, the Rev. Jonathan Boucher, the author of a 'Provincial Glossary,' the publication of which from the posthumous manuscript commenced in 1829, but which has not been continued beyond the letter R. Mr. Locker resided at Windsor from 1815 to 1819, when he was appointed secretary to Greenwich Hospital. During his residence at Windsor his attention was called to an article in 'The Windsor Express,' in which was pointed out the deplorable want of books adapted to the large number of young people in the surrounding schools, and for many years he devoted large portions of his leisure to the promotion of education in National and other schools. Mr. Locker sought the acquaintance of the writer of that article, Mr. Charles Knight, then the editor of the Windsor paper; and they together projected and jointly edited 'The Plain Englishman,' almost the first, not the very first of any literary pretension, of those cheap and popular miscellanies which the growing ability of the great bulk of the people to read imperatively demanded, in the place of miscellaneous or childish tracts. Those of the friends of education, such as the present Archbishop of Canterbury, were among its contributors. Mr. Locker's own papers in the miscellany are excellent models of popular writing—plain, energetic, affecting. His articles on the Bible and Liturgy, which have been reprinted in a series of sermons delivered to the Crew of the Caledonia, Lord Exmouth's flag-ship, are admirable examples of clear exposition and earnest exhortation. Mr. Locker, after filling for several years the important duties of secretary to Greenwich Hospital, became the Resident Civil Commissioner of that great institution. The improvements which he introduced into its management were results of his active and comprehensive mind. Of these improvements the Naval Schools are striking instances. Himself an accomplished draughtsman and an ardent lover of the arts, he founded the Naval Gallery at Greenwich by his judicious exertions. In 1844 Mr. Locker's health so failed that he gave up his valuable appointment and retired upon a small pension, his fine faculties outweighed beyond the hope of recovery. Mr. Locker was the intimate friend of many distinguished men amongst his contemporaries. To use Mr. Lockhart's expression, he was an old and dear friend of Scott's. He died on the 10th of October 1849.

LOCKERTIE.

LOCKHART, JOHN GIBSON, was born in 1794 at the manse of Cambushan, in Lanarkshire, Scotland; his father, who was of an old Lanarkshire family, being then minister of Cambushan, in Lanarkshire, was a member of the Established, or Presbyterian, Church of Scotland. His mother was related to the celebrated family of the Erskines. When Lockhart was two years of age, his father removed from Cambushan to become one of the city clergymen of Glasgow; and his talents were shown during his course at the Glasgow University; at the end of which, while still only in his sixteenth year, he obtained, by the unanimous voice of the professors, the Snell exhibition to Balliol College, Oxford, at the early age of 17, which he began to study with a zeal and ardour which have never been surpassed by any eminent Scotchmen have been trained. In 1813 he took honours as a first-class man in classics; and in 1817 he graduated B. C. L. at the university—a degree exchanged for the higher one of Doctor of Laws. After his graduation, he, with many, and acquiring the language and seeing much of the literary society there, he settled in Edinburgh as a member of the Scottish bar in 1816. He never had much practice as a lawyer however, but from the first devoted himself to literature, and has since made up for his few years, with those who, with Wilson as their chief, were then beginning to dispute the literary supremacy of the Scotch Whigs, as represented by Jeffrey and the 'Edinburgh Review.' When Blackwood started his magazine in 1817, Lockhart, the young Scot, wrote for it, and after a short while, with a considerable number of the famous 'Chaldee Manuscript' and of the earlier 'Necatos Amorosianos' papers were written by Lockhart, though Wilson afterwards made the magazine his own. It was in consequence of Lockhart's literary connection with Blackwood and Scottish Toryism that he became acquainted with Scott, who looked with a kindly interest on the efforts of those young men of the same politics as himself. The first meeting of Scott and Lockhart took place in 1818, and from that time until Scott's death in 1832, they were almost inseparable, and it was Lockhart 'the gallant and adventurous' who spent a prolific period in Lockhart's literary career. He wrote his translations of 'Spanish Ballads' for 'Blackwood,' afterwards published collectively; in 1821 he published anonymously his 'Valerius, a Roman Story;' in 3 vols.; this was followed in 1822 by 'Adam Blair, a Story of Scottish Life,' in 1 vol.; by 'Reginald Dalton, a Story of English University Life,' in 3 vols., 1823; and 'Matthew Welford,' in 1 vol., 1824, each showing great power in a peculiar vein; and in 1825 he wrote 'The Roman of Aragon,' a life of Charles III, remembered 'Life of Napoleon,' for 'Constable's Miscellany.'

In 1826 Lockhart removed to London to succeed Gifford in the editorship of the 'Quarterly Review.' He continued to edit the 'Review' in 1827, and succeeded the late Mr. Aubrey. In his hands the 'Review' maintained and increased its reputation; and not a few of the most powerful articles that appeared in it during the seven-and-twenty years of his editorship, came from his own pen. He was particularly happy in biographical sketches, combined with criticism. One paper of this kind—that on 'Theodore Hook'—has been reprinted by itself.

On Scott's death in 1832, the task of writing his biography naturally devolved on his son-in-law Lockhart. The task was accomplished in 1837-39, when the voluminous 'Life of Scott' was given complete to the world. Those portions of the work which related to the fall of Scott's pecuniary fortunes, provoked some controversy at the time; but the work as a whole has taken rank as one of the most interesting and admirable biographies in the language. It has been said by those who knew Lockhart, that such was his practical sagacity that, had his illustrious father-in-law had the benefit of his actual assistance in the management of his affairs, the calamities which ruined Scott towards the close of his life could certainly never have happened.

In 1849 Lockhart was appointed by Sir Robert Peel to the office of auditor of the Duchy of Cornwall, with a salary of £1,500. In addition to this and his large literary income he had inherited some small property in very easy circumstances. His last years however were embittered by a series of bereavements. His eldest son, the 'Hugh Littlejohn' of 'The Tales of a Grandfather,' had died in early life; his second son, and surviving son died at a later period; and there remained only
corolla; and in this expedition he was again severely wounded. In 1803 he became full colonel, and aide-de-camp to his Majesty, and for a short time occupied the post of adjutant-secretary of the Household.

He was also appointed by the British sovereign to attend to the court of St. James, and was present at the coronation of the Emperor of Russia, and also at the coronation of the Emperor of France, under which circumstances he was required to assist in the service of Lord Castlereagh, with whom he maintained an intimate and constant correspondence during the whole of his later years. He was a constant attendant on the Emperor of Russia, and was present at the coronation of the Emperor of France, under which circumstances he was required to assist in the service of Lord Castlereagh, with whom he maintained an intimate and constant correspondence during the whole of his later years.

ing an elongated body, with dorsal fins and one anal fin, a
chin with one or more barbules.
L. molea, the Ling, is a very valuable fish, scarcely less
so than the Cod. Its quantities are taken in the Western
Islands, the Orkneys, on the Yorkshire coast, and the
Scilly Islands; and may be traced nearly all round the
Irish coast. The fishing for them is by hand-lines and
long-lines; and besides a portion that is consumed fresh, the
fish are mostly kept in salt, either in brine, washed, and
dried, or used in brine are sold to be used for attracting fish.
The liver produces oil, which is used by the poor to supply the
cottage lamp, also as a medicine. In Zetland the principal fishing
for Ling is from May to August. On the Yorkshire coast
the young are called Drizelles. In Cornwall they are caught in
January and February, and their favourite haunt are the
mouths of the rocky valleys of the ocean.

The Ling is exceedingly prolific, and has a most voracious
appetite, feeding on young fish, not sparing anything that
has a head or a tail, and a maw or a beak. In that no previous
art is required to catch it. It is tenacious of life, and sur-
vives great injury. Mr. Conch says he once saw a Ling that
had swallowed the usual large hook, shaft foremost, of which
the line was fastened to the stomach, and as it turned round,
it entered the opposite side of the stomach and fastened the organ together in complicated folds; yet having escaped by breaking the line, it survived to swallow another book, and was taken several days after.

The most usual length of the Ling is from three to four
feet; Pennant mentions having heard of one which measured seven feet; and Mr. Conch has known them weigh 70 lbs.

The body of the Ling is slender, more elongated than that of the Hake; roundish; head flat; gape large, lower jaw
shorter than the upper, with a single barbule at its ex-
tremity; teeth in the upper jaw small, and very numerous,
those in the lower jaw longer and larger, forming a but
a single row; lateral line straight, scales small, firmly adhe-
sing to the skin; two dorsal fins of equal height, the first
short, commencing near the head, not pointed as in the Hake,
but with most of the rays even; second long, im-
mediately behind the first, reaching nearly to the caudal;
their tips being the most elevated, but not in a line forming
the eighth or ninth ray of the second dorsal fin; the fin im-
nediately behind it is long, resembling the second dorsal fin,
and terminating on the same line with it; caudal rounded at
the upper edge, back and sides yellow, grading to olive;
sometimes cuneous without the lower anal having dusky
belly silvery; ventrals white; dorsal and anal edged with
white; caudal marked near the end with a transverse black
bar; the extreme tip white.

L. m. aegu, the Burbot, or Eel-Pout, is the only British
species of this numerous family of fishes that lives per-
manently in fresh water, and prefers in this country slow
running rivers; but it is neither so generally known, nor so
much esteemed or encouraged, as from the goodness of its
flavor it deserves. It is said to be found in various parts of
the north of Europe, Siberia, Asia, and India. In this
country it is rather local. It occurs in the Cam, and in
some of the rivers of Norfolk and Lincolnshire. The
Trent produces it, and Nottingham market is occasionally supplied with samples for sale. The Burbot is not unlike the eel in some of its habits, concealing itself under stones,
waiting and watching for its prey, which consists of aquatic
insects and young fishes, under arches and near eddies, into
which and round which animals are brought and brought
by the current of the water. It feeds principally during the
night, and like the eel, is most frequently caught by trimmers
and night-lines. The Burbot is sometimes called the
Cottager's pet of lurking and hiding itself in holes like a rabbit. It spawns in February and March, and from this,
very tenacious of life, and is said to have lived a considera-
table time in a cold and damp situation, fed on small fishes
and raw meat. In this country it has been known to attain the
weight of 44 lbs, but a common weight is about 3 lbs.

The flesh is firm, white, and of good flavour, and is some-
what considered superior to that of the eel. As the Burbot
is extremely hardy, it might be increased in any quantity,
without the expense of the trouble and cost of the experiment. It would thrive well and multiply in large lakes. The length of the fish is from one
to two feet; the head depressed, smooth; jaws equal; chin
with one barbule; the gape large, with small teeth above and
below near the jaw, the eye just in the middle of the site; gill-opening large; the length of the head as compared to that of the body as one
to four; the form of the body cylindrical, compressed pos-
teriorly; the first dorsal fin is small and rounded, the second
elegant, reaching nearly to the tail; both dorsal fins nearly
uniform, base of the first placed very forward, narrow, and pointed; the pectoral fins large and rounded; the anal fin begins on a line behind the commencement of the second dorsal fin, but ends very nearly on the same
plane; the tail small and slightly pointed; the colour of the
body yellowish-brown, clouded and spotted with darker
brown, and covered with a mucous secretion; the under
parts lighter; the lateral line indistinct and straight; scales
small; the fins parraking of the colour of the part of the
body from which they emanate, these of the lower region
being much the lightest.

(Yarrell, British Fishes.)

LOTUS, a genus of Plants belonging to the natural order
Linguissaeae. It has a calyx with 5 nearly equal teeth;
keel is much shorter than it. The petals are ovate or ob-
vient at their upper margin; longer filaments dilated up-
wards; style knobbed at the base, bilobed, subulate; pol
linear; many-seeded, 3-valved, imperfectly divided by trans-
versal wings.

L. corniculata, Common Bird's-Foot Trefoil, is found
in pastures and on dry banks in Great Britain. The claw
of the standard is obovate, transversely vaulted; calyx-
teeth straight in the hand, subulate from a triangular base,
points of the two upper calyx-teeth rounded; a few of the
third line double, tubercle horizontally placed; flowers
shorter, about 1.5 cm long.

L. angustifolium is found in the south of England, near
the sea. It has the claw of the standard linear; calyx-teeth
straight in the hand, subulate from a triangular base, two
upper ones diverging; heads 8-12-flowered; subulate
ovariable; stamens roundish oval.

L. hybridum is found near the woods in Devonshire and
Cornwall. It has the claw of the standard subulate; calyx-
teeth straight in the hand, subulate; pod rugose, terete, twice
as long as the calyx; beak elongate, sessile, bent downward;
heads few-flowered; leaves obovate-lanceolate; stipules
half cordate; stem procumbent. There are many other
species of this genus, none of which are of any
importance.

LOUGHOR. [Glamorganshire.]

LOUIS PHILIPPE, King of the French, Duc d'Orlans,
and Chartres, and Comte de Neuilly, was the eldest son
of Louis Philippe Joseph, Duc d'Orléans, the Philippe
Edifié of the Convention [Orleans, Hous of], and Louise Marie de
Bourbon, daughter of the Duc de Penthièvre.

Louis Philippe himself was born at Paris, October 26th,
1773, his father, Duc d'Orléans, sickly and feeble, and the
judicious training of Madame de Genlis was well
calculated to draw out the good qualities of those who were
brought up under her charge. In his infancy he bore the
title of Duc de Valois and afterwards of Chartres. In 1831
the young Duc de Chartres, having been elected to the
collegium of the 14th regiment of dragons, assumed the
command of that corps. It is said that almost his first act
of authority was the rescue from the fury of the mob of
some deputies whom the king wished to be brought before
the court, an act of which the king had been expressly
instructed by the government from all ecclesiastics. On
this occasion he showed great tact and presence of mind, and
was subsequently received the honour of a civic crown from
the municipality of Vendôme for rescuing M. de Saint
Brisson. The events of the following year were very
much the same, and from that time he became popular among the French people. In August 1794, the young
Duke quitted Vendôme in command of his regi-
ment for Valenciennes. Whilst he was stationed there, he
was proclaimed against Austria, and in the April follow-

Digitized by Google
he entered on his first campaign. He fought his first battle at Valmy on the 30th of September, and on the 6th of November was again engaged under Dumourier at Jemeppe.

At this period the Revolution was rapidly advancing to a crisis, and on the 10th of October (1792) against the Bourbon race; and though his father, the Duc d'Orléans, had renounced his titles and had been enrolled as a citizen under the name of Philip Édouard, his son, Louis Charles de Bourbon, future Louis XVI., was born in Paris, where, having been made the drape of the revolutionary party, and having voted for the death of Louis XVI., he was dragged to the scaffold in his turn, January 21, 1793. For several months after this date the young duke remained at his tutorship under the care of Montpensier, and the Committee of Public Safety summoned before them both the Duc de Chartres, and his faithful friend Dumourier. Aware of the sanguinary character of the tribunal before which they would have to plead, they fled to the Belgian frontiers, and made their escape into the Netherlands, then in possession of Austria. The Austrian authorities gladly received the fugitives, and even offered to bestow on a commission in their army; but he refused to take up arms against his country, and retired into private life. In April he set out disguised as an English traveller, on a tour through Germany, and journeyed through Léige, Aix-la-Chapelle, Cologne, and Koblenz, towards Switzerland. The resources at his command were small, and he was beset by dangers wherever he went. The English authorities restored him to the duchy of Aix-la-Chapelle, at the same time fled the country together with Madame de Genlis, and met her brother at Zurich. The authorities of that canton, in fear of the French government, restored the Duc de Montpensier, and put an end to the secret abode in Zoug; but being discovered, the duke placed his sister and Madame de Genlis in the convent of St. Claire, near Beaumarchais, adopted the disguise of a traveller, and started on a fresh journey of danger and adventure.

His funds were nearly exhausted, and when received from M. de Montesquieu the offer of a post as professor in the college of Reichenau, close by the confluence of the Upper and the Lower Rhine. He at once offered himself for examination, and was distinguished by the celebrated David Chabaud, in October 1793. Here he remained eight months, during which he was engaged in lecturing on mathematics and geography. At this time he accepted the friendly offer of M. de Montesquieu of an asylum at Beaumarchais, where he remained in concealment till the close of 1794. His retreat being again discovered, he next went to Hamburg, in the hope of being able to procure a passage to America; but being disappointed, he crossed over via Copenhagen to Norway, Sweden, and Finland, where he traversed almost empty and desolate regions, for the purpose of making the course of circumstances at Paris had changed, and the Directory became anxious to compromise matters with the Orléans family, by procuring their voluntary removal to America. The Duc de Montpensier and the Comte de Beaujolais, who had been thrown into prison as dangerous subjects, and at the same time in order to procure the restoration of his mother's states which had been confiscated, Louis Philippe (whom we shall henceforth term the Duc d'Orléans) accepted a passage to the United States, and having left the Elbe in September 1796, reached Philadelphia, where he was joined by his two brothers. The next year the three brothers agent travelling through the United States, and on the return of this excursion, the duke gained great repute for his medical skill, by lancing a vein in his arm in an attack of fever. He afterwards performed the same operation for an Indian chief; in reward for which he was allowed to pass the night upon the large rug at the feet of the wild sovereign and his relatives. Having made the acquaintance of Washington at Mount Vernon, they returned to Philadelphia, whence they proceeded to New Orleans, and thence to Havana. Here the Spanish authorities declining any further intercourse with them, the Duke of Kent was induced to go over to New York, and crossing to England in a sailing packet, they landed at Falmouth in February 1800. The royal exiles were welcomed in London by the King, the Prince of Wales, Lord Grenville, the Marquis of Hastings, and the leaders of the politics and fashion of the day. An Orléans mania prevailed through London, and an invasion of France to effect the restoration of the Bourbons was even talked of. After a short time the brothers settled at Twickenham, in a house formerly occupied by General Pollock, and since known as Orleans House. The Duc de Montpensier, whose health had long been declining, died at Twickenham in May 1807, and was buried in Westminster Abbey. Soon afterwards the health of the Duchess of Brabant, sister of the Duc, failed also, and having gone to a warmer climate in obedience to the order of his sovereign, accompanied by the duke his brother, he died at Malta in 1808. Being now rejoined by his sister, who for fifteen years had lived in retirement in Hungary, and by his mother, whom he maintained in a sumptuous palace at Aix-la-Chapelle, the Duc de Montpensier died, at Milan, on the 17th of March, 1808. It was not till 1815 that he gained the affections of the Princess Amelia, the second daughter of the king, to whom he was married November 25, 1809. For upwards of four years the Duc d'Orléans resided at Palermo without taking any part in the public affairs of Europe, if we except a visit which he paid to Spain in 1810, in the illusive idea that negotiations commenced by the Spanish and English authorities might eventuate in an offer on their part to enthrone to his hands the regency of that country.

In 1814 tidings reached Palermo of the downfall of the Bourbons, and of the expected restoration of the Bourbons. The duke returned to Paris without delay, and was re-instated in his honours and military rank. The return of Napoleon in the early part of the following year again troubled the d'Orléans family. The Duc decided to return to England, to procure a dispensation for his life, and to accompany the royal family to England for safety, the duke took the command of the army in the north in obedience to the orders of Louis XVIII. Rather than endanger the peace of France by family feuds, he resigned his command in the following May, and went to Reichenau, where he remained till Paris after the Hundred Days, in obedience to a decree compelling the attendance of princes of the blood in the Chamber of Peers. He conciliated the popular esteem and respect by his kindness to the Orléans family. He returned to Paris, and took part in the political measures. Louis Philippe, in his place in parliament, publicly protested against the extreme measures proposed by the government against those who had taken part in the revolution, and procured their rejection. Louis XVIII, who regarded him with especial favour, in disgust and revenge, forbade princes of the blood royal to appear in the Chamber of Peers. The Duc d'Orléans revived himself upon the court by entering his son in one of the public colleges as a simple citizen of Paris. He returned to England, and continued his correspondence with his family till the days of that king's life, and the first few years of the reign of Charles X. He did not return to France until 1857, when he took up his abode at the palace of Neuy, where he continued to live as the Prince of Orléans until 1880.

In 4th month he was made a marquis of France, and was the first among the French nobility to hail the king. For the two days of July it was agreed by a provisional government, in which Lafayette, Twickenham, Thiers, and other politicians, took the lead. They naturally turned to the Duc d'Orléans, and in the name of the French crown, invited him to assume the Sardine crown. The Duc, however, once having accepted the crown, and having having been accepted on the 25th of July; and, the preliminary forms having been passed through, on the 9th of August the crown was formally accepted by the Duc d'Orléans, who was proclaimed as Louis Philippe. For seventeen years he sat on his elective throne; and an increase of the wealth and physical progress of a nation be a test, the results of his reign may be advantageously compared with those of the first empire. Peace was preserved without war, the arts and commerce increased steadily. His foreign policy was happy and successful: his sons, the Duc de Némours and the Prince de Joinville, carried the French arms into Algeria; Abd-el-Kader was made a prisoner, and the Bey of Constantine submitted and became a French military colony. Yet the king was not popular at home. He was hated alike by the Legitimist party, in whose eyes he was but a usurper, and by the revolutionists, who sighed for entire emancipation from kingly rule. Besides, there are deep and dark slants upon the reign
Heraclea, founded about n.c. 433 by the inhabitants of Thurii and Siris, was the place of meeting of the Italian League of Cities. In 1846, the Congress of Paris transferred the meetings to Thurii. The city early rose to prosperity, and was in close alliance with Tarentum against the Lucanians and Messapians. The first engagement between Pyrrhus and the Romans took place in the plain between Thurii and the Sybaris. Its site is marked by mounds of rubbish and the foundations of ancient buildings near the farm of Policoro, which is marked on some maps near the mouth and on the right bank of the Agri. Many coins, bronzes, and other antiquities have been found on the site, and a short distance west of it are the two very interesting bronze tables called Tablebe Heracleiaca, which contain a Latin inscription relating to the municipal regulations of the city. On the back is a long Greek inscription of earlier date and of much less interest.

The coins of Heraclea are beautiful masterpieces of ancient art. Zeus the painter, it is said, was a native of Heraclea.

LUCAS, FREDERICK, was the second son of Samuel H. Lucas, Esq., of Croham, near Croydon, Surrey, a member of the qualifying list of practitioners in 1842, and was educated at the London University, where he gained early distinction as a debater. He was called to the bar in 1838, and in the following year became a member of the Roman Catholic Church. In his new position he took an active part as a善celar of the faithful, and became the founder of the "Royal Tablet," newspaper, which he conducted as editor for many years. He was also a frequent contributor to the 'Dublin Review.' In 1849 he transferred the 'Tablet' from London to Dublin, and in 1852 was elected M.P. for Evesham.

LOVAGE, HALECRIA, S. 21

LOWESTOFFE, OR LOWESTOFT. [SUFFOLK.]

LOUXOCLASE, A Mineral belonging to the anhydrous silicates of Alumina. It has nearly the form of Felspat, but is in a cleavage parallel with the 14th di- diagonal. It contains 6 per cent. of soda and 3 per cent. of potash. It is found at Hammond, in the state of New York, in company with Pyroxene, Graphite, and Calepsar.

LOYDIA, or LLOYDIA, a genus of Plants belonging to the natural order Liliaceae. The perianth is persistent and patent; stamens inserted at the base of the perianth; anthers erect; style filiform; stigma trigonous; seeds angular above, flat beneath.

LUCANIA, a province of ancient Italy, bounded N. by the Silurus, the Apennines, and the Bradanus, which separate it from Campania, Samnium, and Apulia respectively; E. by the Gulf of Tarantum, along which it extended to the mouth of the Crathis; S. by Bruttium, and W. by the Tyrhenian Sea, between the mouths of the Leus and Silurus. The territory of Lucania is now comprised chiefly in the modern province of Basilicata; portions of it are included in Calabria and Principato Citi. Under these heads the physical geography of the country is given, and many particulars respecting its ancient towns. The rivers that fall into the Gulf of Tarantum from the Silurus and the Crathis were—proceeding from the north, the Cassaneus, the Acadlandus, the Acritos, the Siris, and the Sybaris. These rivers rise in the mountains that cover all the interior of the province, and run generally in the direction of east by south across a very fertile plain, which skirts the shore of the Tarentine Bay. Along this shore were several celebrated cities founded by early Greek colonies; Metapontum, between the mouths of the Bradanus and the Casaneus; Heraclea, near the mouth of the Crathis; and on its right bank; a little higher up the right bank was Paestum, near the mouth of the Siris and on its left bank; Syracus, near the mouth of the Siris; and Thurii, a few miles higher up in the plain between the Crathis and the Sybaris. On the coast of the Tyrrenian Sea, a few miles from the Silurus, and Elae, or Velia, further south, on the Bay of Elae, and a few miles north of the promontory of Palinurus.

LUCIUS, FREDERICK, was the second son of Samuel H. Lucas, Esq., of Croham, near Croydon, Surrey, a member of the qualifying list of practitioners in 1842, and was educated at the London University, where he gained early distinction as a debater. He was called to the bar in 1838, and in the following year became a member of the Roman Catholic Church. In his new position he took an active part as a speaker of the faithful, and became the founder of the "Royal Tablet," newspaper, which he conducted as editor for many years. He was also a frequent contributor to the 'Dublin Review.' In 1849 he transferred the 'Tablet' from London to Dublin, and in 1852 was elected M.P. for Evesham.

LUF, a genus of Plants belonging to the natural order Cucurbitacae. The male flowers are panicled and yellow; the tube of the calyx hemispherical, segments longer than the tube; petals distinct, dropping off by the base; stamens 6, distinct; anthers very small. The female flowers are solitary; the tube of the calyx oblong, clavate, shorter than the tube; stamens abortive; stigma reniform; gourd ovate, 3-celled, fibrous, internally operculate.

L. amara is found in hedges and dry uncultivated places in the East Indies. It has several stems, slender, rooted to a great extent, but with few branches, pretty smooth, 5-angled; tendrils 3-cleft: leaves slightly 5-lobed, rough; stipules axillary, solitary, cordate, with glandular marks on one side. Male flowers pretty large, yellow, on long erect axillary racemes; the petals with a glandular base near the base and articulated a little above it. Female flowers rather larger, axillary, solitary, pedunculated; fruit oblong, 3 or 4 inches long, and 1 inch in diameter, tapering equally towards each end, 10-angled; when ripe dry, gray, and split; seeds with a glandular base near the base, with elevated minute black dots; every part is extremely bitter. The fruit is violently cathartic and emetic; the juice of the roasted young fruit is applied to the temples to cure headache by the natives of India; the ripe seed was used either in infusions or substances by them to purge.
L. Bindiaus is a native of Hindostan. It is a climbing dicotyledonous plant; the leaves are toothed and 6-angled. Male flowers in racemes. Female flowers solitary; fruit round, echinate, with long, straight, ciliate bristles. It is introduced in northern India a powerful drastic in cases of dropy. The leaves of L. aculeatus are a favourite potherb of the natives of India, and are esteemed very wholesome.

**LUG-WORM.** [Annelida, S. 2] LUMINOSITY OF ORGANIC BEINGS. Organic bodies under certain circumstances become luminous, and on the subject there have been made many discoveries, and the combination of phosphorus at a low temperature, the phenomenon has been called phosphorescence. This luminosity is very constantly developed under the same circumstances by animals and plants. It is exhibited both during the decomposition of the bodies of plants and animals, whilst they are still living. The oldest observations on this subject were made on the wood of trees whilst in a state of decay. This however takes place only under peculiar circumstances. It generally occurs when the wood of trees is buried in the earth whilst they are in a green state, and does not take place when wood is allowed to decompose in the usual way and in free contact with the air. It is also found that the phosphorescence does not take place when the wood is lampblack, or when the specimen is not immersed in a liquid. To exhibit this property will retain it for a long period when kept in a dry place. Albrecht observed luminosity in a tree which during the night at a spot where one of its branches had broken, it was emitting light, and this light can be made to emit this light. Travellers in tropical climates have observed that when plants containing a milky juice are wounded, the juice frequently becomes luminous, whilst it is descending the sides of the tree. The cause of this phenomenon in fresh water is the same as in the wood of trees, the tissues attended with a union of oxygen gas, but what determines the development of light under these circumstances is still unknown.

In living plants luminosity has been frequently observed. It is frequently observed on the leaves of algae, mosses, and other plants; especially of fungi, especially of the genus Rhizomorphus. In the coal-mines in the vicinity of Dresden the species of Rhizomorphus are so numerous as to "dazzle the eye by the brilliant light they afford." [Brauner, S. 1.] The light from decaying wood, as also from the living Rhizomorphus, continues although they are immersed in an extinguishing gas, linseed oil, phosphoric acid gas, oxygen, &c. The phenomenon in both the living and the dead plants is probably due to the same cause.

Another phenomenon also observed is the light emitted by the Mosses. Several species of the genus Schistothecia, which grow in caverns and other damp places, have been observed to give out light. Mr. Babington and other botanists have observed in the dark the virtues of fungi by fire, Funk, Brandenburg, near Essen, Hennock, Hornschuch, Strohe, Unger, Bridel-Briderei, and Agardh, have observed it on the continent of Europe. The two latter attributed this light to a small alge, which Bridel-Briderei called Cupeliopsis emaragdina, and Agardh called Protococcus emaragdinus, which they supposed was parasitic on the moss. Unger however has examined the moss closely, and finds that at certain seasons the tissues of this moss assume a globular form, and being partly transparent, the light is refracted in a way as to present a luminosity on the surface of the vessels.

Another class of these phenomena is that which is exhibited by the flowers of some plants. The first observation was made by Mr. Meissl, the daughter Christina Linne. She was walking in the garden one hot summer's evening, when she observed the flowers of Tropaeolum majus to give forth a stream of light. This was attributed by many to an optical illusion, but the fact has since been repeatedly observed and is often, if not always, observed as other plants. We are not perhaps in a position to say this was not an optical illusion; but if it was, one would expect that it should be more constant. It has also been seen by several observers in different positions, and when one has seen it, the others have seen it also.
from their invariably elevated limits. During this growth the glandular layers the epidermal epithelium extends itself by spontaneous multiplication of its cells (division), while at the same time the fibrous layer surrounding them also grows, and finally constitutes the fibrous membrane of the bronchus and air-cells, together with the vessels and nerves. In the second month from the beginning the large bronchial leaves are already formed; and besides them smaller divisions also, 0.16" in size, may be recognised, originating in the dilated extremities of the bronchus, which even at this time are considerably ramified. As development proceeds, and the resolution of the divisions, these gray granules, as they are termed, become more and more numerous, and ultimately, in the fifth month, are aggregated so as to form smaller lobules of 0.16"-0.48" in size, each of which is considered to be produced from a single glandular or bronchial termination, of the second month. Each of the gray-granules of these lobules, which correspond with the secondary lobules of the future lung, by continued budding, finally constitutes a primary lobule, which, with air-cells of 0.06"-0.08" in size, first becomes distinctly visible in the sixth month, although up to the time of birth new alveoli are constantly superadded. In the newborn child the secondary lobules measure 2"-3"-4"; the alveoli, before they are filled with air, are 0.06"-0.04", and the alveoli of the latter at this time appear to exist in the same number as in the adult, the further increase of the lungs proceeding only from the expansion of all its parts.

The history of the lungs," continues the translator of Kölliker, "presents us real difficulty, except in one point; that is, with respect to the relation of the pulmonary cells to the terminations of the bronchus; but here the difficulties are very considerable. In recent preparations it is obvious that the air-cells communicate in many ways, and in any case that they are not merely terminal on the extremities of the bronchus. If it be desired to investigate the whole subject, inflated and dried lungs (it is better in this case to prepare in an air-pump dry they by itself, or with transparent preparations, or lungs injected with uncoloured substances (wax and resin), are most suitable; and with such a definite result will be obtained, after a series of observations. Before the injection of the bronchus is proceeded with air must be exhausted in the air-pump, for which purpose also, though less conveniently, a well-fitting syringe may be employed. The injection of the blood-vessels is readily effected, and the preparation should be kept wet; sometimes when injected with opaque material, such as lead, the processes of air-collection of the bronchus with transparent substances (Prussian blue, &c), dried preparations are to be preferred. The air-cells and bronchus, the larynx and trachea, are readily examined. The epithelium is procured in thin plates in the section through the lung, as well as ciliated cells. If it be wished to study the alveoli, the air must previously be carefully removed. These are best displayed in man, in whom also all other parts, such as cartilage, elastic elements, muscles, and glands, are easily obtainable."

(Kölliker, Manual of Human Histology, translated for the Sydenham Society by Busk and Huxley.)

LYCOPODIUM. (Botany, S. 2.) LYCIUM, a genus of Plants belonging to the natural order Solanacea. It has an uncoated calyx regularly 5-toothed, or irregularly 3-5-toothed; permanent corolla funnel-shaped or tubular; limb 6 or 10-toothed, or toothed, imbricate in attachment, sometimes plicate; stamens 6, usually exerted; filaments banded and widened at the base; stigma pellitally depressed, or capititate, biculate; berry roundish, 3-valved, propped by the permanent calyx; placenta adnate; seeds numerous, reniform. The species are trees or shrubs usually spinose. Corollas white, yellow, rose-coloured, purple, blue, or scarlet.

L. europaeum has erect loose branches; buds spine"ented; leaves fascicled, ovate, lanceolate, obtuse, or spathulate, bent obliquely; flowers twin or solitary; corolla funnel-shaped, back banded, but short, lobed, 8. It is a native of the south of Europe and the north of Africa: in the Greek islands common in hedges, but scarcely indigenous. The calyx is 8-toothed, ruptured at the side: the orange-pot is large and articulated with red veins; tribe gree

L. barbarum has dependent branches; buds spiny; leaf lanceolate, flat, glabrous, acute; flowers twin, extra-calycal, petals back banded, but short; stamens 8. It is a native of the north of Asia, Africa, and south of Europe. There is a variety having pale corollas and yellowish red berries.

There are about 30 species of this genus described, many of which are of medicinal and pharmaceutical use. They are commonly known by the names of Fox-Thorn.

LYCOPODIUM, a genus of Plants belonging to the natural order Lycopodineae. It has 1-celled 2-valved capsules, containing powders, or 4-valved, containing 1 to 4 granules, with the tip of the capsule incurved, with a filamentous point; spines stalked 2 or 3 together, cylindrical; scales ovalate, triangular, membranous, finely incised, serrated. The stem is prostrate and long; branches short and ascending; spines on long stalks, pale-yellow; scales on the stalks irregularly disposed in which the powder contained in the spore-cases is highly infectious: shaken out and collected it is employed under the name of Lycopode, or Vegetable Brimstone, on the Continent, in the manufacture of fire-works and in pharmacy as a uphill, which when coated may be put in water without being moistened. The plant has long been used as an emetic; a decoction of it is said to be serviceable in removing Feces from the bowels.

L. annotinum has scattered lanceolate leaves; spikes sessile, solitary, terminal; scales roundish, with an alternated point, membranes, and jagged. The branches are rather long and erect, each year's growth is marked by a spot when viewed from under. The leaflets are cylindrical, greenish, yellow, not persistent. It is found on stony mountains in the South of France and in Pyrenees, and is common in the Highlands of Scotland.

L. adpermum, Stev. Leaved Club-Moss, has leaves in tufts, imbricated, acute, keeled, entire; spikes sessile; utile, terminal; scales ovate-lanceolate, flat; branches erect. L. dalmaticum, has leaves peltately expanded, the leaflets are rather thicker than the branch. It is found on elevated mountains in Great Britain.

L. salango, Pit Club-Moss, has leaves in eight rows, curved, uniform, linear-lanceolate, acuminate; capsules not spined, but in the axils of the common leaves; stem erect, forked, level-topped. The stem is short, erect, or slightly decumbent, densely leafy. Occasionally in sheltered positions the stem becomes elongated. In the Highlands of Scotland it is made into an irritating ointment, which is applied in cases of eczema and eczematous conster instant. Internally administered it acts as an emetic and cathartic. Linnæus says the Swedes find the decoction serviceable as a digestive lotion, and in destroying the vomiting it is of great value.

L. inundatum and L. selaginoides are the other British species, both common in boggy places. The most remarkable species is the L. rubrum of Chamisso, Yatun corrado, Great Devil. Sir William Hooker, who calls it L. catesbae, states that it acts most violently as a purgative, and has been administered successfully in Spanish America in cases of elephantiasis. According to Vastring, Club-Mosses are likely to become of importance in dyeing: he asserts that the woolen cloths boiled with Lycopodiums, especially with L. catesbae, acquire the property of becoming blue when passed through a bath of Brazil-Wood. L. pelligraphis is reputed an aphrodisiac. L. aquaturn is remarkable for its hygrometrical properties, rolling up into a ball when dry, and expanding when moisture is supplied.

(Dalouf, Classbook of Botany: Babington, Manual of British Botany: Lindley, Vegetable Kingdom.)

LYCOPISS, a genus of Plants belonging to the natural order Boraginaceae and the tribe Anchusae, which have the achene of the contraceptive, an excavated spore surrounded by a tufted ring at their base.

Lycopsis has the calyx in 6 deep segments; the tube of the corolla curved; the limb oblong. The species closely resemble Lycopus, but the limb is rather broader, and the tube rather shorter. L. arvensis, the Bugloss, has lanceolate crass-ductae very hirsute leaves; the calyx of the fruit is bell-shaped, erect. The flowers are small and blue. The whole plant is very hirsut, with strong hairs, each rising from a scaly base; it is common in the fields and hedges of Great Britain and Europe.
LYCOPUS, a genus of Plants belonging to the natural order Lobelias. It has a 4-fid corolla, scarcely longer than the equal 6-toothed calyx; stamens 2; anther-cells parallel or ultimately divergent; 2 upper stamens wanting, or rudimentary, or rarely perfect.

2. *Eurosperma* inhabits wet ditches and sides of ponds, and is known popularly under the name of Gipsy-Wort, because gipsies are said to stain their skins with its juice. It has stalked ova-loblong leaves, glabrous or pubescent, opposite. Flowers small, in dense whorls. It is found on banks of streams and ditches in Great Britain, LYDD. [Kavv.]

**M**

MAAS, or MAES, NICOLAS, a celebrated Dutch painter, was born at Dort in 1625. He was a scholar of Rembrandt, whose manner he imitated with so much skill that it was thought difficult to distinguish the works of the pupil from those of the master. But a visit to Antwerp, where he diligently studied the productions of Rubens and Jordaeus, led Maes, to adopt a new and more independent style; and one in which, while retaining his former neatness and delicacy of touch, and breadth of chiaroscuro, there was more freedom of handling and variety of colour. Maes was an ear in the history of his art, and produced subjects of great pictures, chiefly domestic interiors, but he eventually devoted himself to portrait painting, especially after his removal to Amsterdam, where he settled in 1676; and where he rose into high reputation as a portrait painter, and acquired a considerable fortune by the practice of that lucrative branch of art. He died at Amsterdam in 1693.

British mentions several plates etched by him. In the National Gallery there are three paintings by him—like most of his genre pictures, of small size, but elaborately finished—The Cradle, The Dutch Husbandman, and The Idle Servant.

MACDIARMID, JOHN, was born about 1780 in Edinburgh, where he received his early education, partly at the common schools and partly at the university. He was apprenticed to Mr. Calder, publisher, whence he was removed to the Commercial Bank, where for a few years he was discharged highly responsible duties. While so engaged he ceased not to pay attention to his literary studies, was occasionally amanuensis to Professor Playfair, contributed poetry to the Scots Magazine, and was an active member of a debating society called the 'Forum.' In January 1817 he became editor of the Dumfries Courier, of which he afterwards became the proprietor. It was in this position that MacDiarmid first introduced the character of the provincial press by introducing originality and taste into the conduct of it, his newspaper becoming highly successful, and a model for others. Mr. MacDiarmid had a partiality for natural history, and was always desirous of the acquisition of the animal specimens which occurred; but though a laug was sometimes raised at his accounts of enormous gooseberries or marvellous turnips, it is not known that he ever willingly exaggerated. In addition to this, he drew attention to the antiquities and natural beauties of Dumfrieshire, and the adjacent counties of Kircudbright and Wigtown, not only in the newspaper, but by separate publications, 'The History of Dumfries,' the 'Guide to Moffat,' etc. His other works were— a 'Life of Cowper,' published in 1817; a 'Life of William Nicholson, the Halloway Post'; 'Sketches of Nature,' 'The Scrap-Book,' etc. After conducting the paper with extraordinary vigour and fertility, he died on November 12, 1829.

SMITH, VICTOR, who distinguished Scotch naturalist. He was born in the Isle of Harris, and early acquired a taste for natural history, and having gone to reside in Edinburgh, became the assistant of Professor Jamieson in the Natural History and Geological Museum of the University. He was afterwards appointed to the position of Con

The following estimate of his character appeared in a notice of his 'British Birds' in the 'Atheneum' for 1829:—

"Dr. Macgillivray was a naturalist, and one of no mean order. Had he confined his attention to a few of the subjects of the vast field over which he laboured with unwearied industry through a long life, he would perhaps have attained a yet higher position as a man of science than that which he has already reached. With a constant, unvarying, and unerring eye on the sea-above, he had an eye to every natural object that surrounded him, and the interest with which he regarded them is expressed in the numerous papers and works which he has
written on botany, zoology, and zoology. Though a list of Dr. Macgillivray's works would alone occupy a large space, yet he was not a man of the closet. Though one of the most diligent of compilers, he was a laborious original investigator. Whilst he lived by natural history as a profession, he pur¬

sued it as a science, and in return for the scanty means which it impeded to the formation of his closet, and the want of existence, he rendered a large amount of observation made with great labour and self-sacrifice. Although naturally an amiable man, he has frequently in his works—as is often the case with men of an ardent character, to himself strongly on the views of others, and in this way he made many enemies during his life. Now that the grave has closed over him, these with whom he most differed will be the first to admit of his career only to admire.

MACHZERIUS. A genus of plants belonging to the natural order Lepidinae. One species, M. Schomburgkii, produces the Iaka Wood of Guiana, remarkable for its brown and black streaks, on which account it is employed in hairnet-work.

MACYLLLETH. [Montgomeryshire.] MACLURA, a genus of Plants belonging to the natural order Rosaceae. The fruit of M. aurantiaca, the Osage Orange, is as large as the fist, orange-coloured, and filled with a dry, white, native taste. It smears their faces when going to war. The wood of M. nitidioria is the dye-wood called Fustic; it contains Morine, a peculiar colouring substance; its fruit is pleasant; and used in American medicine for the same purposes as the black mulberry. According to Martius, both the other species of the genus yield succulents in Brazil. (Lindley, Vegetable Kingdom.)

MACROCYSTIS, a genus of plants belonging to the natural order Liliaceae, and the tribe Laminartdei. The enormous fronds produced by M. pyrifera have been spoken of by many navigators. They appear to be from 600 to 1800 feet in length; the leaves are long and narrow, and at the top which is in each a vessel filled with air, without which it would be impossible for the plant to support its enormous length in the water, the stem not being thicker than the finger, and the upper branches as slender as common pack¬

thread. This plant was seen by Dr. Joseph Hooker in 61° 8' lat., where he was vegetating patches wherever the water was free of ice-bergs.

MACRÖDIPTERYX. [Night-Jar.] MACRÖGLOSSA. [Chefroptra.] MACROOM, county of Cork, Ireland, a post and market¬

town, and the seat of a Poor-Law Union, is situated on the river Sallane, and on the road from Cork to Killarney, in 61° 56' N. lat., 8° 56' W. long., distant by road 244 miles W. from Cork, and 163 miles S.W. by S. from Dublin. The population is 3747, in 619 houses, in the workhouse of Macroom Poor-Law Union comprises 25 electoral divisions, with an area of 179,106 acres, and a population in 1851 of 37,394. The town consists principally of one street nearly a mile in length, occupied in great part by cabins and other mean dwellings, and the central part of the town is served by shops. The parish church, the Roman Catholic chapel, the sessions-house and bridewell, and a market-house, the dispensary, and the Union workhouse are the public edifices. Petty-sessions are held monthly. Fairs are held on the 12th day of May, July, September, and November. There is a large weekly market. Macroom Castle is a fine old structure overhanging the river.

MACROPERIP, a genus of Plants belonging to the natural order orchidaceae, the Arum is the most celebrated of the narcotic Pepper-Worts. It has corotate acuminate many-nerved leaves; solitary axillary spikes, very short, pedunculated, and spreading. The rhizome is thick, woody, rugged, and aromatic. It is used in tincture against chronic rheumatism. Macerated in water it forms an intoxicating beverage, of which the Othetians make use as a medicine; they make themselves drunk, after which very copious perspiration comes out; this lasts three days, at the end of which the patient is cured.

MACHRONIUS. [Salam.] MADATEUS. [Chemoptera.] MADELEY. [Shropshire.] MAELSON. [Lancashire.] MAES. [Mae. S. X.] MAGENDE, FRANCOIS, a distinguished French physician and physiologist. Although his father practised as a physician in Paris, he was born at Bordeaux on the 15th of October 1783. He was soon after brought to Paris, where he had the misfortune to lose his mother. His father took an active part in the revolutionary movements of the period, was mayor of the 10th arrondissement, a member of the Hospital Council, and of the Comune of Paris. He also served in the National Guard. After the execution of his pupil, and afterwards his demonstrator of anatomy. At the age of twenty, after an examination by concours, he was appointed aide d'anatomie (prosector) in the Faculty of Medicine, and afterwards, the raterwards, became a deliverer enthusiastically to the study of surgery, but he was induced by Dupuytren to give up this branch of the medical art, and devote himself to the practice of medicine. He was subsequently appointed physician to the Hotel Dieu. In 1819 he was elected a member of the Academy of Sciences; he was also a member of the Academy of Medicine, and in 1831 he succeeded Professor Recamier, who had resigned on the accession of Louis Philippe to the three of France, in the chair of anatomy in the College of France. He was in charge of the medical clinic of the University of Paris, which used as one of the most illustrious physiological experimentalists and discoverers. His larger works are as follows:—1. "Fon¬

bles pour la Preparacique et Emplie de plusieurs nouveaux elements" (1826). This work was originally speedily translated into all the languages of Europe. It contained an account of the action of those potent active principles found in plants, which had at that time been introduced into the practice of medicine, more particularly by the work of Guyton de Morveau. It included such remedies as morphia, strychnia, prussic acid, and others, on the operation of which the animal system Magendie had successfully experimented. 2. "Prin¬

elementaire de physiologic." This work was originally published in French and English, and for many years it was one of the best known and most useful books for the student of physiology. It was translated into French and German, and is known as "Les Phénoménas physiques de la Vie." These were a series of lectures delivered at different times, and collected together by M. J. James, and published in 1834-41. These were also translated, though occupying four volumes in German. 4. "Lecons sur les Fonctions et les Maladies du Systeme nerveux." These also were lectures delivered at the College of France, and were published in two volumes in 1839, 5. "Lecons sur le Sang." These lectures on the blood were published in 1842, and afterwards translated into French, Italian, and other languages, and are known as "Les Phé¬

noména physiologiques et cliniques sur le liquide cephalo-rachidien, or cerebro-splanical," Paris, 1842. In addition to these large works, Magendie published a large number of papers, which will be found scattered through the "Comptes rendus" for the years 1826-41. He wrote several philosophical and medical experiments, a periodical which he started in 1821, and which he continued to edit for ten years. He was also a contributor to several of the Dictionaries which appeared in France during the commencement of the present century. He was the author of the "Dictionnaire de Medecine," the "Chirurgie pratique," the "Encyclopédie des Graus du Monde," and the "Dictionnaire de Medicine usuelle." Although Magendie wanted the generalising power which was possessed by his friend at the head of European physiology, he was most industrious in the progress, and ingenuity in devising of physiological experiments. It was as an experimenter that he produced a lasting impression on the progress of physiology. In fact so numerous were his expe¬

iments at one time, and the result of these in the physiological societies of France, that he thought it necessary to interfere. Some of the results of his physiological enquiries are too important to be passed over in this notice:—

1. He successfully demonstrated what had been only suspected by previous physiologicalists, that the veins were organs of absorption. His experiments on this subject have been regarded by physiologicalists as setting this question at rest, and proving that the veins are the great agents in the absorption of nutritive matters.

2. His numerous experiments on the absorption of poisons led to a more accurate apprehension of the nature of their action on the human system. He first demonstrated that
axyria acts upon the spinal cord, and destroys by paralysis the nerves of respiration, thus inducing asphyxia.

4. He investigated with great care the action of hydrocyanic or prussic acid on the human system, and drew attention to its value as a remedy in certain forms of cough arising from irritation in the lungs.

5. Long before the chemical nature of food was understood, Magendie pointed out that non-nitrogenous foods were innutritious, and that the brain was a mass of muscular tissue, and showed how little it depended on the action of the stomach itself.

6. He performed a series of experiments on the admission of air into the veins, and showed bow likely this was to be a source of death in operations about the thoracic cavity.

7. In a letter to Bell the honour of having discovered the real functions of the spinal nerves. Walker had demonstrated the existence of two roots to the spinal nerves. Bell showed that the nerves performed two functions, that of sensation and volition, and that these were sometimes separate, but the final demonstration of the two roots of the spinal nerves being devoted to the two separate functions, seems to have been first clearly established by Magendie.

8. These more important discoveries and investigations must be added a large number of experimental researches upon the functions of the brain, its parts and nerves. If these did not lead to immediate and decisive results, they have opened many new facts by means of which others have since been guided to more satisfactory conclusions.

Magendie was made a Commander of the Legion of Honour, and few men gained more of the respect and confidence of the government in matters of public health, whilst amongst the medical profession he was the subject of a long series of eulogies, written by his account of his great talent and original genius. He died on the 8th of October 1855.

MAGHERAFELT. [Londonderry.]

MAGONIA, a genus of plants belonging to the natural order of Rhamnaceae. The male flowers have 5-parted nectarial reflexed calyx; petals 6, linear, and unequal; disc unequal between the petals and stamens, on one side long and double, in the other short, simple, and rugose; stamens 6, dissilicate. Hermaphroditic flowers as in the male, but stamens much smaller and not diclinous; ovary 3-celled, many-seeded; styles curved; stigma 3-lobed; capsule large, woody, 3-valved, loculicidal; seeds large, flattened, surrounded with a wing; hilum in the edge of the wing.

M. pseudomesium. a small tree common in the western deserts of North America. In the few books of Miers on the flora of the islands of the Gulf of California, it has downy branches; leaves 6, ovate or oblong, sessile, deeply emarginated and downy; the flowers in a terminal sessile or stalked panicle from 9 to 16 inches long; calyx downy, yellowish-green; petals linear, obtuse above, in the middle smooth and dark purple, at the edges and point downy and green; fruit a large, woody, globe, 3-cornered, somewhat depressed capsule, with 3 valves, 3 cells, and many seeds. The ashes of this plant are extremely alkaline. The bark is used for soothing the swellings produced in the skin of horses by the stings of insects. The leaves of this species and M. gibrosa are poisonous to fishes.

MAPIE-MOTH. [Abrasia.]

MAI, ANGELO, CARDINAL, and Prefect of the Vatican Library, was born at Milan, a member of the old family of the Barberis, who for several centuries held the dignities of the See of Bergamo, Italy, March 7, 1792. He received his early education in the village school, and his first master in the higher studies was the Jesuit Father, Lewis Monzi do Capistiano. In 1799 Monzi, struck by the taste and capacity for classical learning which Mai displayed, selected him, along with four other youths of the village, to enter the novitiate of the Jesuit society, which, although elsewhere suppressed, the Duke of Parma, with the sanction of the Pope, restored in 1796, with consent of the Pope and a majority of his duchy. In this community Mai resided till the provisional restoration of the society in Naples (1804), whither he was sent as Professor of Greek and Latin Literature. About the end of 1805, he was transferred to Rome for the same subject. In 1810 the lower parts of the Papal States were removed to Orvieto, on the invitation of the bishop, Giambarischi. He was then admitted to priest's orders; and to the opportunities which he thus enjoyed of intercourse with two learned Spanish fathers of the Jesuit order, he was enabled to acquire a knowledge not only his familiarity with the Hebrew language, but what much more sensitively influenced his after-career, his accurate knowledge of palaeography, and his skill in deciphering.

Mai returned to Rome in 1806, just about the time when the contest of Pius VII. with Napoleon was reaching the crisis; and an order issued by the vicar-general, commanding all subjects of the kingdom of Italy to return to their respective provinces, compelled him to change his residence once again. Happily for the interests of literature he settled at Milan.

The Ambrosian Library of that city had long been known rich in manuscripts of the highest interest—the remnant of the treasures which after the fall of the republics had been collected by the Medici, the Este, the Farnese, and those of Bobbio and Lucca, and of some of the suppressed Benedictine convents of the Protestant cantons of Switzerland. Many of its best treasures had been made public by Muratori, Mahillon, and the Benedictine editors; but there it yet remained a department entirely unexplored, which Mai soon appropriated to himself, and which has since come to be regarded as exclusively his own—that of palimpsest or re-written manuscripts, in which the original writing has been effaced or effaced by other writing put over it. Through the influence of Padre Monzini and the recommendation of his friends, and especially of Count Mellerio of Milan, Mai was admitted an associate and, eventually a member, of the Accademia, and, from the date of his arrival in Milan till his ultimate removal to the Vatican, he laboured in his novel editorial career with a zeal and success not unworthy of the traditional glories of his country. His first essay as an author was a Latin translation (with a sombreant of Lacordaire's 'De Republicationes') (1813), the original of which had been published by a Greek named Andrew Mustoxidi in the previous year; but this was only the prelude of his far more remarkable successes in the decipherment and publication of palimpsest manuscripts.

Mai further dedicated to this inquiry Knittel's 'Codex Ephraemi,' Wetstein's readings of the Old and New Testament from the 'Codex Vysobradus,' Klinel's portions of the Gothic Bible of Ulpian, Peter Brunn's fragment of the unity-first book of Livy, and Barrett's palimpsest of the Gospels, palimpsest literature was entirely untried. Within a few years Mai deciphered and published from palimpsest sources two volumes of illuminated fragments of Cicerio's 'Orations,' a volume of letters and other writings of Fronto, the preceptor of Marcus Aurelius, three portions of Plutarch's 'Romana' of Plantus; a lost work of Porphyrius, the Platonic; some portions of Dionysius of Halicarnassus; two works of Philo Judæus; eight orations of Lysimachus; an oration of Isaeus; several manuscripts of Virgil's 'Aeneid'; and several other works of the same character.

During this time Mai, although a member of the Jesuit Society, had not taken the solemn vows of the order, which indeed he could not be formally restored by papal authority till 1814. It was then thought, both by his superiors and by the authorities at Rome, that he could render more effective services to literature and to religion by remaining attached to the Ambrosian Library. Accordingly, with the full approval of all the authorities, he withdrew from the Society, and re-entered, as a simple priest, at Milan till 1819, when he was called to Rome as chief keeper of the Vatican Library, canon of the Church of St. Peter's, and domestic prelate of the Pope Pius VII. Soon after his establishment in the library of the Vatican, he was sent to France to visit the palimpsest of Fronto which he had already prised at Milan; having happily discovered in the Vatican the missing portion of the manuscript from which the Milenaue fragments had been prised, and which (as well as the Milanese manuscript) originally belonged to the library at Bobbio. In the following year he published the work by which he is best known out of Italy—a large and interesting portion of the long-lost 'De Republica' of Cicero, the fragments of which he arranged in a continuous narrative, and added with considerable ingenuity, and with all the known extracts of the work which had been preserved from ancient authors. The whole text he illustrated by a critical commentary of exceeding interest, which at once established his reputation as one of the first scholars of the time.
ship. Selecting from the vast and till then imperfectly explored manuscript treasures of the Vatican, he prepared his 'Scriptores veterum Collectio et Vaticanici BibliothecaeDescriptions et Index', published between 1835 and 1844. In the course of this work, he discovered many true authors, by collecting fragments of the same work and dovetailing them together into intelligible order, in selecting from a heap of unknown materials all that is unpublished, and deciding upon the question of its genuineness or its intrinsic value; in a word, in all the thousand investigations which fall to the lot of a critical editor treading on untrod ground, he possessed a skill and acuteness which can hardly have been equalled by any other master of the art. He was accustomed to account for the vast variety of subjects which engaged him, must be regarded as little short of marvellous.

The private character of Cardinal Mai has been well described as the very ideal of a Christian scholar. Eminently popular, his work was developed in a spirit of Greek and Latin, sacred and profane, theological, historical, patriarchal, and philosophical. One of the volumes, the second, is perhaps the most curious of the entire, containing consider- able fragments, recovered from a very early palimpsest manuscript, and giving a key to the works of the ancients historians, Polybius, Diodorus Siculus, Dionysius of Hali-
carnassius, Dion Cassius, Appian, Daphnes, Eusapia, and others.

The 'Vaticana Collectio' was quickly followed by a similar collection in ten volumes, svo. 'Classici Scriptores ex Codicibus Vaticanis editi,' completed in 1838 which included some of the editor's earlier publications (especially the 'De Republica'); although, with the exception of about two volumes, its contents are entirely new. While he was engaged in the publication of this series he held the laborious and responsible post of secretary of the Propaganda, to which he had been appointed in 1833; and it was observed with wonder that his extensive literary engagements never weighed upon his work with the diligence and sagacity of his active and business-like habits, the promptness of his decisions, and the prudence and discretion of his whole administration, are still gratefully remembered by the members of the various missions under the surveillance of the Propaganda.

After five years of service in this laborious office, he was named (1835) cardinal, at the same time with his friend and successor in the Vatican Library, Mezzofanti; and soon afterwards was appointed to several important and confidential offices in the Roman court, chiefly of a literary character. He was named successively Prefect of the Congregation for the Supervision of the Oriental Press; Prefect of the Congregation of the Index; and Prefect of the Congregation of the Propaganda. In in his work in this last department, he has contributed to the still more congenial post of Librarian of the Vatican Church.

This elevation did not interrupt in the slightest degree the literary labours in which he had been engaged. Scurcey was the collection of 'Classici Autorum' completed when he commenced a similar one, also in ten volumes, svo. 'Spicilegium Romanum' (1835-44), equally interesting and valuable in its contents, and a fourth collection entitled, 'Novae Patrum Bibliothecae,' published in 1835 in six volumes 4to., and containing more than 1000 volumes, of Muratori, and indeed far more extraordinary than the others, collections, from the circumstance that it was compiled from the mere gleanings which had escaped the research of the earlier critics and collectors. Several years before, he had undertaken to edit the 'Liber canum' of the Old and New Testament with various readings and prolegomena. The text of this edition was printed many years before his death, but its publication was delayed in order that it might be accompanied by the intended prolego-
mena. He died however at Albano, September 6, 1864, in his seventy-third year, leaving this great work still unpub-
lished; and it is much to be regretted that since his death no trace has been found among his papers of the long-expected disquisitions which he had intended to prefix to the 'Codex Vaticanus.' It is conjectured either that, engrossed by his other manifold editorial occupations, he deferred year after year this anxious and difficult task, or that, dissatisfied with the execution, he in the end destroyed what he had prepared.

Cardinal Mai's abilities as an editor were of the very highest order, while his collections comprise an infinite variety of authors of every age, of every country, of every language. All the types of the literary departments, Latin and Greek, he appears equally the master. Whether the subject be theology or history, or law, or languages, or general literature, his learning is never at fault, and his critical sagacity never fails. He is the master of the minute and difficult questions which so often arise in connexion with ancient literature, and he is the true author, in collecting fragments of the same work and dovetailing them together into intelligible order, in selecting from a heap of unknown materials all that is unpublished, and deciding upon the question of its genuineness or its intrinsic value; in a word, in all the thousand investigations

which fall to the lot of a critical editor treading on untrod ground, he possessed a skill and acuteness which can hardly have been equalled by any other master of the art. He was accustomed to account for the vast variety of subjects which engaged him, must be regarded as little short of marvellous.

Dissolves with effervescence in nitric acid. Decomposes and blackens before the blow-pipe, and becomes partly a black scoria. With borax it fuses to a deep green globule, and ultimately a black crust of copper, the surface of which is glistening, or highly polished, being at times partly covered with crystals of copper. The solutions are of a brownish-green color. Green Malachite usually accompanies other ores of copper, and forms incrustations, which when thick have the colours blended, and extremely delicate in their shades and blending. Perfect crystals are quite rare. The mines of Siberia, at Nischne Tagil, has afforded great quantities of this ore. A mass partly disclosed measured at top 9 feet by 18 feet; and the portion uncovered contained at least half a million pounds of pure Malachite. Other rich Cherty localities are in Shetland, in the Tyrol, Cornwall, Australia, and the island of Cuba. This mineral receives a high polish, and is used for inlaid work, and also ear-rings, snuff-boxes, and various ornamental articles. It is not much prized in Jewellery. The larger masses are usually smeltingly reduced in Russia, which are worked into slabs for tables, mantel-pieces, and vases, which are of exquisite beauty, owing to the delicate shadings and reactions of colour. In the Great Exhibition of 1851 there were magnificent specimens of this material in the shape of vases and vases sent thither by the Emperor of Russia. At Versailles there is a room furnished entirely with tables, chairs, &c., wrought in Malachite, and the same to be found in other European palaces. At Nischne Tagil, a block of Malachite was obtained weighing 40 tons. Malachite is sometimes passed off in jewellery as turquoise, though easily distinguished by its shade of colour and much inferior hardness. It is a valuable ore when abundant, but it is seldom smelted alone, because the metal is liable to escape with the liberated volatile ingredient, carbonic acid.

MALACHIUM, a genus of Plants belonging to the natural order Ceratophylidae. It has 5 sepal; 5 biform or entire petals; 10 stamens and 5 styles; the capsules opening with 5 biform valves.

M. aquaticum, Water Chickweed, has a decumbent stem, angular, ascending, and covered with glandular hairs; cordate-obovate leaves, acuminate, seersle, the lowest one stalked; flowers scattered, solitary, perigynous, bipartite, and rather exceeding the calyx; capsule exceeding the calyx. It is usually found in wet places in Great Britain.

MALLOW, Marsh. [Malva.]

MALTHACITE. [Mineralogy, S. I.]

M A N.

In classifying the races of men, it must be remembered that the division and subdivisions which are employed do not resemble those which are used in the systematic classification of plants and animals. When the whole of the species of the vegetable or the animal kingdom have to be arranged, then we divide them into various primary and secondary groups, which are called Classes, Families, or Orders, Genera, Species, and Varieties.

Now Man himself is but a species; he belongs to a subordinate group of a large division of the animal kingdom. Zoologically considered, Man is an animal belonging to the class Vertebrata, in the order Mammalia, the sub-order Hominoidea, the genus Homo, and species sapiens. The characters of this species as given by Blumenbach have been stated elsewhere. [Man.]

The same is the arrangement of the races of men, with the definitions given by Dr. Pickering, an American traveller and writer, in his work 'On the Races of Men':—

a. White.

1. Arabian. — The nose prominent, the lips thin, the beard abundant, and the hair straight or flowing.

2. Abyssinian. — The complexion hardly becoming florid, the nose prominent, and the hair curled.

b. Brown.

3. Mongolian. — Beardless, with the hair perfectly straight and very long.

4. Hottentot. — Negro features, and close woolly hair; and the stature diminutive.

5. Malay. — Features not prominent in the profile, the complexion darker than in the preceding races, and the hair straight or flowing.

6. Papuan. — Features not prominent in profile, the beard abundant, the skin harsh to the touch, and the hair curled or frizzled.

7. Negroid, apparently beardless, the stature diminutive, the features approaching those of the negro, and the hair woolly.

8. Indian, or Telingan. — The features approaching those of the Arabians, and the hair, in like manner, straight or flowing.

9. Ediopian. — The complexion and features intermediate between the Telingan and Negro, and the hair curled.

10. Australian. — Negro features, but combined with straight or flowing hair.

11. Negro. — Close woolly hair, the nose much flattened, and the lips very thick.

The most recent writer and greatest authority on the races of man is Dr. R. G. Latham, who, in his work on the 'Minor Varieties of the Human Race,' proposes the following arrangement. He has admitted in the first place, like Cuvier and other previous writers, he adopts but three primary varieties of the human species:—

The termination in 'ide' employed here seems preferable to the use of terms such as class, order, family, tribe, or other words which have another use, either in this or other systems of classification. The terms Mongolida, Atlantida, and Japetida are not derived from a community of meaning in the things they express. Thus, the first includes a nation, the Mongols, who occupied a portion of eastern Asia, and were at one time the conquerors of the world, and are regarded as typical of a large portion of the human race. The Atlantidae are entirely rarely found in Africa; the Japetidae include the races of men in Europe, who are traditionally descended from Japheth; hence the name selected to express them.

1. Mongolida. — The people comprised under this variety have the following physical conformation:—The face is broad and flat, which either arises from the great development of the zygomatic arches, or from the distance between the parietal bones on each side of the head. There is often also a great depression of the nasal bones, which contributes to give a flat appearance to the face. The profile of the forehead is retiring or depressed, seldom found perpendicular. The profile of the jaws is prognathic or projecting, seldom found on a level with the forehead. The eyes frequently present the peculiarly called oblique. The skin is of a mixed character, never truly white, and very rarely of a jet-black; still it often presents what would be called a black or white colour. The eyes are generally of a dark colour. The hair, as a general rule, is straight, long, and black; in some instances it is curly—rarely woolly—and more rarely still light-coloured.

The languages of the people belonging to this variety are either characterized by the absence of cases (apotic), or having inflections to be shown to have arisen out of the union of different words (agglutinate). They are very rarely amalgamate.

The distribution of this variety is very wide over the surface of the earth. It finds its greatest development on the continents of Asia and America, and is to be entirely possessed of the earth. The Persians of northern and western Persia, the Kurds, the Belochoi, the Afghans, the Tajiks of Bokhara, and the Siapoo must all be regarded as
belonging to the *Japetida*. On the other hand, although we shall find the *Japetida* the principal occupants of Europe, there seems to be little doubt that the Lapps and Finns of Scandinavia, the Magyars of Hungary, the Turks of Turkey, the Parsees and Parsee emigrants of Persia, the Natives of British India, and probably even the Albanians or mountaineers of ancient Illyria and Epirus, all belong to the *Mongolida*.

From the analogy of language this variety is made by Dr. Latham, he adds to the whole of Central Asia from the Polynesian Islands, as well as those of America. Although at first sight the physical differences between the Asiatic *Mongolida* and the inhabitants of the islands of the South Seas and the continent of America might look so great as to be a sufficient ground for separating them into individual ethnological groups, yet it has been found that even physical characters fail to afford a line of demarcation. Thus, the late Dr. Morton, of America, thought that "the squared or rounded head, the flattened and vertical occiput, the high cheek-bones, the semi-elliptical, the large quadrangular orbits, and the low receding forehead," were characters that would distinguish the American from all other varieties. When however we examine the languages of the American continent we shall find that the Equinoxmax present so strong a relation to that of the other races that we cannot deny their affinity to the American races; and it is amongst the Equinoxmax that we find a departure from the physical type of a peculiar American form, and a strong relationship with the Asiatic Mongolida. It is in these relations as this which have induced ethnologists to regard the American Indian as a form of the variety of mankind to which the followers of Ghenghis Khan belong.

The influence of the races included under the variety of *Mongolida* must be regarded as rather material than moral. They undoubtedly form by far the largest portion of the human race, and occupy a considerable space in the history of the world. They have, by the sword, established some of the greatest empires that the world has seen. China is at this moment an example. Their empires have however crumbled to pieces, and left no deep impression on the world. Such is not the history of the *Altaicidae* and *Japetidae*, the first of which includes the Mongols and the Mohammedans, and the last the Greeks, Romans, and modern European races.

The *Mongolida* are divided by Dr. Latham into groups as follows:

1. *Altaic Mongolida*. The term *Altaic* is taken from the Altaic Mountains in Central Asia, these being a convenient geographical centre for the different nations and tribes composing this division. It embraces two stocks, the *Seriform*, and the *Turanian*.

2. *Seriform stock*. The *Seriform* stock has the physical conformation of the Mongol; and its languages are either wholly apotic or with only occasional inflection. The area inhabited by these people is China, Tibet, and the Indo-Chinese or Trans-Gangetic Peninsula as far as Malaya; the Himalayan and parts of the Sub-Himalayan range of mountains.

3. *Turanian stock*. In this stock the chief people are the Chinese, Tibetans, Boni, Siamese, Kambas, Burmees, the Indo; and several unplaced tribes are added by Dr. Latham.

4. *Turanian stock*. The *Turanian* stock has the physical conformation of the Mongold; the languages are not monosyllabic. They are found from Kamchatka to New Guinea, and from the Arctic Ocean to the frontiers of Tibet and Persia. The countries included are the northern parts of the Chinese empire, the greater part of Siberia, Mongolia, Tartary, Eastern Turkistan, Asia Minor, Turkey, Hungary, Esfahen, and Lapland.

5. *Tungusian branch*. The chief Tungusian group include the Tchepojirins on the Lena, the Lemerits on the Sea of Okhotsk, and the Manchou rulers of China.

6. *Tork branch*. This includes the Uighurs, the Turks of the Sandy Desert, Turks of Khoten, &c., the Kalmucks of the Russian empire, the Tibetans, Turks, and Uighurs of the Russian empire, and the isolated Yukats of the Lena.

7. *Ugrian branch*. This includes the Voguls, the Permians, the Tchermis, Finlanders, Esthoinians, Laplanders, and Hungarians.

**B. Dissierian Mongolida.** The term *Dissierian* is taken from a name ancient scribe Dissierius. The tribes included in it have a modified Mongol organisation, the languages are

(pancosyllabic) few-syllabled and agglutinate. Of all the languages not belonging to the Seriform stock of the last section they approach nearest to the apotic state. They are in common with the languages of the Mongold, of the *Ugrian*, the *Sami*, the *Legrians*, the *Mandchus*, the *Melqiti*, the Iron, and the Circassians.

Of this group, Dr. Latham observes, "To have used the word 'Caucasian' would have been correct but inconvenient. It is already misapplied in another sense, that is, for the sake of denoting the so-called Caucasian race, otherwise said to consist of Jews, Greeks, Circassians, Scotchmen, ancient Romans, and other heterogenous elements. In this sense it has been used in more than one celebrated work of fiction. In such and such only, it is otherwise than out of place as applied to these varieties."

**C. Oceanic Mongolida.** The epithet Oceanic is applied to this group, because, with the exception of the peninsula of Malacca, the tribes belonging to it are the inhabitants of islands exclusively. With the exception of Mauritius, the Isle of Bourbon, Ceylon, the Seychelles, the Maldives, and the Laccadives in the Indian and Japanese empires, with the islands to the north thereof in the Chinese Sea, every inhabited spot of land in the Indian and Pacific Oceans is inhabited by tribes of one and the same race which are embraced by this division. It is supposed that the human species spread over these islands, but apparently nowhere else.

"In the peninsula of Malacca," says Dr. Latham, "and on no other part of the mainland of Asia, is an oceanic tribe to be detected. Although united by Dr. Latham in the Mongold, it exhibits two extremes—the black, yellow, olive, brunette, or brown, with long, black, and straight hair. Another class is black rather than yellow; the hair is sometimes long and straight, but in other cases crisp, curv, frizzy, or even woolly. The social, moral, and intellectual difference between these two classes is more than their physical. The black division inhabits New Guinea, Australia, Tasmania, New Ireland, and the islands between it and New Caledonia. The brown division occupies all the rest of the oceanic area, Sumatra, Borneo, Java, the Moluccas, the Philippines, the South Sea Islands, the Carolinas, &c. The names given to these divisions are as follows:

1. For the lighter-complexioned straight-haired type—Malays, &c., *Altaicidae*;
2. For the type that partakes of the character of the African negro inhabiting New Guinea, Australia, and what may be called the continuous localities for the unmixed black—*Negrito*;
3. For the tribes with any or all of the Negrito characters, dwelling side by side with Malays in Malay localities, or in localities disconnected with the true Negrito area—the blacks of the Malayan area.

**D. Hyperborean Mongolida.** The physical conformation of this section is that of undersized Mongoldians. The languages are agglutinate, and the difference between these two classes is more than their physical. They are subject to either Russian or China. Their religion is either Shamanism or an imperfect Christianity. They are found on the coasts of the Arctic Ocean, and the coasts of the Yenisei and Kolim. The principal divisions are the Samoiids, the Venetsians, and the Yakibiru.

**E. Peninsular Mongolida.** This section comprises races very widely distributed. Some of these lie within the Arctic circle, others as far south as 26° N. lat. Their physical conformation is Mongold. Their languages are agglutinate, and the difference between the two classes is more than their physical. The races occupied by these races are the islands and peninsulas of the north-eastern coast of Asia. The people included in it are the Koreans, the Japanese, the Aino, the Koriats, and the Kamchatkals.

**F. American Mongolida.** This section embraces the original inhabitants of the whole continent of America. By the term Mongold they are Mongoldians as a distinct family. Their connection with Mongoldida seems however to be established by the Eskimo, who are physically Mongold and Asiatic, but philologically American. Of the Eskimo Dr. Latham remarks, "Unimportant as are the Eskimo in a political and historical view, their peculiar geographical position gives them an importance in all questions of ethnology; since one of the highest problems terns upon the affinities of this family."

Digitized by Google
"It has long been known that the nation which inhabits Greenland and Labrador is the nation which inhabits the north-western parts of Russian America as well. It is found on the American side of Behring's Straits, and it is found on the Asiatic side also. So that the Eskimo is the only family common to the Old and New World; an important fact in itself, and one made more important still by the Eskimo localities being the only localities where the two continents come into proximity. Now if these facts had stood alone, unmodified by any phenomena that detracted from their significance, they would have been no more a mystery than the peopling of Europe. Such however is not the case. They neither stand alone, nor stand unmodified. The reasons that lie against what is at first blush the common sense notion that 'How have the Eskimos arrived?' are chiefly as follow with

1. The distance of the north-eastern parts of Asia from any probable centre of population—cradle of the human race, so called. For these parts to have been the passage, Kamtschatka must have been fully to overflowing before the Mississippi had been trodden by the foot of a human being.

2. The physical differences between the Eskimo and the American Indian.

3. The difficulties presented by the Eskimo language.

4. It is only these two last reasons to which I attribute much validity. The first of the three I put low in the way of an objection; that is, not much higher than I put the system of the Mongol, with the drifting of Japanese junks, and the effects of winds and currents upon Polynesian canoes. Without at present doubting whether the occurrences bare alluded to have happened since America was peopled by the present race, I limit my attention to the second, that is, to the question of how. And here, I believe, that by any such unsatisfactory processes the original population found its way; in other words, I believe that our only choice lies between the doctrine that makes the American nations to have originated from one or more separate pairs of progenitors, and the doctrine that either Behring's Straits or the line of islands between Kamtschatka and the peninsula of Allitska, was the highway between the two—worlds from Asia to America, or vice versa. I say vice versa, since it by no means follows that because Asia and America shall have been peopled by the same race, the original of that race must necessarily have arisen in Asia; inasmuch as the statement, that the descendants of the same pair peopled two continents, taken alone proves nothing as to the particular continent in which that pair first appeared. Against America, and in favour of Asia, being the birth-place of the human race—its unity being assumed—I know many valid reasons; reasons valid enough and numerous enough to have made the notion of the New World being the birth-place of two parts of man into which I know no absolutely conclusive ones. Omitting however this question, the chief primâ facie objections to the view that America was peopled from north-eastern Asia lie in the

1. Physical Differences between the Eskimo and the American Indian. Stated as he it stands in the Eskimo is essentially a Mongol in physiognomy. His nose is flattened, his cheek bones project, his eyes are often oblique, and his skin is more yellow and brown than red or copper coloured. On the other hand, in his most typical form, the American Indian is not Mongol in physiognomy. With the same black straight hair, he has an aquiline nose, a prominent profile, and a skin more red or copper-coloured than the native's. Putting aside marked characteristics, moral as well as physical, it is not surprising that the American should have been taken as the type and sample of a variety in contrast with the Mongol.

2. Philological arguments. Few languages, equally destitute of literature, have been better or longer known than the Eskimo. For this we have to thank the Danish missionaries of Greenland—Egea more especially. From the grammar of Fabricius' Eskimo, many Eskimo phonemes are translated into English. The next step was to become languages of low compound words, and of regular though remarkable inflections. It was known too to be very unlike the better-known languages of Europe and Asia. Finally, it has been admitted to be, in respect to its grammatical structure, at least different.

We need not here enumerate the various tribes embraced in this section, as it includes the whole of the original races found on the American continent.

G. Indian Mongolidea. The races belonging to this section are found in Hindustan, Cashmere, Ceylon, the Maldives and Laccadives, and part of Beloochistan. They are found mixed or contiguous to the Japeldes of Beloochistan and Cabul, and various Sermif tribes. They present two extreme forms, one with the skin dark or even black, the other of a brunette colour, with a skin of great delicacy and cleanliness. The social condition of caste prevails amongst them. The principal religions are Brahminism and Buddhism, with a variety of intermediate creeds. Their ancient literature is in the Sanscrit, and their alphabets are derived from that language. They embrace the following divisions: 1, the Tamuli; 2, the Pallindas; 3, the Brahli; 4, the Indo-Gangetic; 5, the Purbutti; 6, the Cashmirean; 7, the Ganglese; and 8, the Maldivian.

II. The Atlantidea. In their physical character the face is not so broad and flat as in the Mongolidea. The jaws project, are prognathic, whilst the nose is generally flat; the forehead is retiring; the cranial dolichocephalic, that is, there is less space between the parietal bones of the skull, whilst its length remains the same, than there is in the last variety; the eyes only rarely open obliquely; the skin is mostly jet-black, presenting however lighter shades, and very rarely approaching a pure white; the hair is crisp, woolly, very rarely straight, and still more rarely light-coloured. The languages among the Atlantidea belong to the so-called classical. They are seldom or never found with a truly amalga-

The great district of the development of the natives which are brought together under the above definition, is Africa. Perhaps the greater diversity of inhabitants than Africa, or races of men that at first sight appear so evidently distinct. All previous ethnologists have placed the Hottentot, the Negro, and the Brahman in a very different position to the Assyrian, the Babylonian, the Mohammedan, and the Jew; but in Dr. Latham's classification we find these brought together under the common variety Atlantidea. The analogy of language has led to this opinion; and the transition from the least to the greatest of these races is so gradual that no investigation of their physical structure with which we are at present acquainted, would be sufficient to break down the affinity discovered in their languages. No part of Africa seems to be inhabited by any race but these of the Atlantidea. The Syro-Arabian or Semitic nations, however, which are now classed amongst the Atlantidea, are found occupying a considerable area in the south-western part of Asia. The people of these races are far removed from the Negro and the Hottentot, and the Semitic has none of the great symmetry of form, and considerable cerebral development. However small may have been the influence of the lower types of this race on the world, there can be no doubt of the vast impression produced by the Semitic nations. We may here pass over the nations of the ancient Chaldean, Egyptian and Babylonian empires, and fix attention on the religious history of the Jews. Here, amidst the surrounding Paganism, we find the worship of the one true God maintained by this small race amongst the Semitic nations; and through them the religion of Christ, which is destined to react on all the other races of mankind. It is also among these races that compound of Judaism and Christianity, Mohammedan, has sprung up; and however inferior it may be to the Christian religion, can by no means be said to have any beneficial influence it has exerted on the races who have embraced it.

The following is Dr. Latham's division of this group:—

A. Negro Atlantidea. The negroes have a black, unctuous, and soft skin; the hair woolly; lips thick; maxillary profile prognathic, frontal profile retreating; nasal depressed. They inhabit the low lands, sea-coasts, and bulrushes. The rivers, deserts, savannah, Caumba, Gambia, and Upper Nile. They are nearly limited to the tropic of Cancer. They are divided into Western Negroes, Central Negroes, and Eastern Negroes.

B. Kaffir Atlantidea. The language of the Kaffir supplies a broad distinction between them and other Atlantidea races. Their physical conformation is modified negro. They occupy a district in Africa (east and west) from the north of the equator to the south of the Tropic of Capricorn. The chief divisions are, 1, Western, 2, Southern, 3, Eastern, 3 C
C. Hottentot Atlantaide.—"The Hottentot stock," says Dr. Latham, "has a better claim to be considered as forming a separate race, than any other section of mankind. It can be shown bowever that the language is no more different from those of the world in general than they are from each other." The Hottentots occupy the southern extremity of Africa. They are of a low stature; limbs are very long; the hair is brown or yellow; their complexions are light; cheekbones prominent; nasal profile depressed; hair in tufts rather than equally distributed over the head. They are divided into the Hottentots proper and the Saabs. The latter are found between the Reggoveld and the middle portion of the Orange River.

D. Nilotic Atlantaide.—These people have a modified negro conformation, and inhabit the water-system of the Upper and Middle Nile. Their chief divisions are, 1, Gallas; 2, Agous; 3, Nubians; 4, Bishari.

E. Amanirgh Atlantaide.—Amanirgh is a term equivalent to Berber. These people are found on the coasts of the Mediterranean and the whole north-western quarter of Africa. They present modifications of both the negro and Arab types. Their chief divisions are, 1, the Siwahs of the Oasis of Siwah, the ancient Ammonium; 2, Kabyles of the range opposite to Atlas. The Tuaricks of the Sahara; 4, Ounanches of the Canary Islands.

F. Egyptian Atlantaide.—This section includes the ancient Egyptians, the subjects of the Pharaohs and the Ptolemies, and the modern Copts as far as they are of unmixed blood. They extend probably from the Nile, from Egypt, to the Mediterranean. The physical conformation of the ancient Egyptians is gathered from their mummies. The modern Copts have the hair black and crisp or curled; the cheek-bones projecting; lips thick; nose depressed; nostrils wide open; mouth large; a yellowish to a dull-brown; eyes oblique; flat and tall and fleshly.

G. Semitic Atlantaide.—This section embraces the most highly developed forms of the Atlantaide. The Semitic races are found in Abyssinia, Arabia, Palestine, Syria, Mesopotamia, part of Kurdistan. They are light-complexioned, and referable to three types—the Arab, the Jew, and the Kaldani. Their influence on the world has been pre-eminently moral, spiritually as well as intellectually. Their religions are pre-eminently monothestic in the later parts of their history. Their alphabet is the earliest in the world, and, with the exception of the Ethiopic, is written from right to left. The chief divisions, which are more or less artificial, are Syrians, Assyrians, Babylonians, Phoenicians, Egyptians, Ethiopians, Cappadocians, Elamites, Cyprians, Philistines, Canaanites.

With the Beni-Terah (sons of Terah), father of Abraham, are found the Jews, who are remarkable amongst the nations of the east for their early intellectual culture, and for the moral and religious influence their writings have produced on the world.

III. JAPETIDE.—This variety includes most of the nations of modern Europe. Physically, they present characters superior to the two other varieties. Their face is not flat, and is moderately broad. The jaws project but little, the nose is often very prominent, and the frontal profile is not uncommonly nearly vertical. The skull is shaped generally as the last; the opening of the eyelids is straight, and very rarely oblique; the skin is white, or bronde; the hair is never woolly, varying much in colour, frequently very light; the eyes are black, blue, or gray. The great European races are very apt to become fastidious, and have many acquired inflections. In a few instances they are allucinated.

The Japetide form the principal part of the nations of Europe, they do not exclusively occupy this district of the world; they are found in the valley and delta of the Nile, as the Nubians; in the region of the Levant, as the Syrians, Assyrians, Babylonians, Phoenicians, Egyptians, Jews, Cretans; in Egypt, Ethiopia, Cappadocia, Elamites, Cyprians, Philistines, Canaanites.

With the Beni Terah, sons of Terah, father of Abraham, are found the Jews, who are remarkable amongst the nations of the east for their early intellectual culture, and for the moral and religious influence their writings have produced on the world.

The influence of this variety of mankind on the history of the world, has been much greater than that of the other two. If we add to the Semitic races those due to the truth of Christianity, its adoption and propagation in a pure form has been mainly due to European nations. It became early identified with the civilization of Greece and Rome; and passing from the nations where it obtained its early triumphs, it has spread over the world, the religion of the great Anglo-Saxon race, which on both sides of the Atlantic is increasing with extraordinary rapidity.

Dr. Latham divides the Japetide into two divisions—Occidental and Indo-Germanic.

A. Occidental Japetide include the races called Celtic or Kelts. The Keltic languages were separated from the common mother-tongue subjoined to the evolution of the persons or words, but anterior to the evolution of the case or object of the grammatical inflections. The present area of this race is Britain, Wales, the Highlands of Scotland, the Isle of Man, and Ireland. The original area occupied by the Kelts, which have been constantly removed, is the Scottish Lowlands, England, Gaul north of the Loire, and part of Switzerland. It is probable also that they occupied parts of Baden, Bavaria, and northern Italy. The Taurisci of the Tyrol, the Scordisci of Illyria, the Galts of Asia Minor, the Celt-Iberians of Spain, and the Germanic races of northern Germany are generally regarded as the Kelts.

They have two types of complexion in the British islands: the Sibarian type having eyes and hair black, complexion dark, and ruddy tinge, and chiefly found in South Wales; the Hibernian type having gray eyes, yellowish, red, or sandy hair, and light complexion; they are found in Ireland. Dr. Latham gives the following as their chief divisions:—

1. Kelts of Gaul, falling into—\(a\). the proper Cels; \(b\) the Belgae. Both extinct or incorporated.

2. British Kelts, falling into—\(a\). the Cambrians; \(b\) the Picts, which are extinct or incorporated.

3. Gauls. \(a\). Scotch Gauls; \(b\). Irish Gaels; \(c\) Maxmets, or Celtic Kelts of the Isle of Man.\n
These are the Kelts, extending from the Ettruscans to the Iberian frontier.

Their line of population seems to have been from Celts and Dunkirk to England, from England to Scotland, and from Scotland to Ireland.

B. Indo-Germanic Japetide.—The language of this group were separated from the common mother-tongue subjoined to the evolution of the cases or classes of nouns. They are less evidently allucinated than the Keltic. This and the previous group are sometimes called Indo-European, and thus embracing all the Japetides. The Indo-Germanic Japetides are divided into two classes—

1. European Indo-Germans.—These are divided into—

1. The Goths embrace—

a. The Teutons, which are again divided into—

1. Meogoths.

2. High Germans, including Hessian, Thuringian, Franconian.

3. Low Germans, including—

1. Batavians.

2. Saxons, embracing—

* Saxons of Hanover, and Anglo-Saxons of England.

** Saxons of Osnaburg and Westphalia.

*** Nortdalbingian. Extinct.

3. Frisians.

4. Scandinavians, embracing—

1. Icelanders.

2. Swedes.

3. Norwegians.

4. Danes.

2. Sarmatians. This comprises the Lithuanian and Slavonic divisions, and these are divided into—

1. Of the Lithuanians Dr. Latham says—

1. Of all the Japetides they preserved their original paganism longest.

2. Of all the Japetides they have had the least influence on mankind.
The Slavonic division includes—

a. Russians.

b. Servians.

c. Holstein.

d. Poles.

e. Serbs.

f. Polabic Slavians.

3. Mediterranean Indio-Germans. These include the Greeks and Romans of antiquity, and their modern descendants.

II. Persian and antiquity,地中海 that the Persian.

• Ulvrians. Such a position, he was at the beach, and February was thirty-seven years. Snipe of the Snipe.

MANN.

3. Of the Japets, they speak a language nearest in structure to the Sanscrit.

3. Mediterranean Indio-Germans. These include the Greeks and Romans of antiquity, and their modern descendants.

II. Ayran Indio-Germans.—Dr. Latham says the whole of this class is hypothetical. It includes the Parthians, who embrace the Kurds, the Balochi, the Afghan, the Siaposh, and other contiguous races in Asia. The unplaced stocks are the Armenians and Iberians.

MAN, FOSSIL. [Anthropology, S. 2.]

MANBY, CAPTAIN GEORGE WILLIAM, the author of several inventions applied to the saving of life in shipwreck, was born at Hilgay in Norfolk, on November 25th, 1765, at his residence Pedestal House, Southwell, near Great Yarmouth, on November 18, 1854, thus having nearly completed his eighty-ninth year. He adopted the military profession, but appears to have retired from any active duty after he had attained the rank of captain in 1803, when however he was appointed barnack-master at Great Yarmouth. Here in February 1807 occurred the loss of the Sniepe gun-brig, when he saw sixty-seven persons drowned within a few yards of the beach; and, in the same gale, so many vessels were lost, that forty-seven dead bodies were cast upon a line of coast about thirty miles in extent. Such calamities induced him to devise means of assistance by throwing a line over the vessel. This was at first proposed to be done by a baleta; but a successful experiment with a small mortar, when he threw a line over a church, led him to prefer the use of gunpowder. The great difficulty to be overcome was as to the connection of the shot with the rope. Chains broke on the discharge. At length, stocking strips of raw hide closely plaited, were found to answer, and on the 12th of February 1808, when the crew of the brig Elizabeth was in imminent danger, about one hundred and fifty yards from the beach, having lashed themselves to the rigging with the sea breaking on them, Capt. Manby's mortar was instantly fired, and in what would have been a hopeless position, Captain Manby threw a line over the vessel, a boat was hauled off by it, and the crew of seven men were brought to land. In the same severe winter Captain Manby rescued the crews of several vessels by similar means. In 1818 his services were brought before the House of Commons. A committee was then appointed on the subject of the saving of life in shipwreck. The merits of previous inventions for the same object were brought before that committee, especially the Patent Bell invented by Bell of Forth, who in 1793 had communicated to the Society of Arts a plan for throwing a rope from a mortar from the vessel itself, and to whom 50 guineas had been awarded after some experiments were performed. That plan however would have been obviously very difficult of application in the case of a vessel in a raging sea. Captain Manby having been reported of with high approval by the Committee, received a pecuniary recompense from the Exchequer, and was employed to report upon the means of the coast from Yarmouth to the Fifth of Forth. He advised that mortars, constructed on his principle, should be stationed at various points; in 1814 the House of Commons addressed the Prince Regent on the subject; and within two years, one station was established. The attention which was thus given to the subject of the preservation of life in cases of shipwreck, was further expressed through associations which were formed throughout the country chiefly by Captain Manby's exertions. He also contrived means of obtaining a sight of a vessel on a dark night, by the use of a description of firework throwing stars to burn at a certain height; and he suggested the use of shells, filled with a burning composition, to allow the crew to discover the sight of the vessel. His plan of manufacture of ropes to prevent mildew and rot, dressing vegetable mucilage, and using a solution with sugar of lead and alum in equal parts; and he suggested various improvements in life-boats. Late in life he visited the Northern seas, chiefly on the North Coast of Staffa, and invented a harpoon which he had invented. For his various inventions, which were the means of saving upwards of a thousand lives, he received at various times 7000L. from the British nation, and the thanks of the chief sovereigns of Europe.

MANDAMUS. The Writ of Mandamus, mentioned P. C. v. xiv. p. 347, and which can only be obtained in the Court of Queen's Bench, is now usually termed the Prerogative Writ of Mandamus, in order to distinguish it from the writ mandamus which is applicable in certain cases in all the other Superior Courts of Law.

The proceedings by Prerogative Writ of Mandamus may be resorted to, as has already pointed out, in cases where a public inconvenience or a private wrong is occasioned by the omission of a public duty, and no sufficient remedy is afforded by an action for damages. This remedy was originally confined in its operation to a limited class of cases affecting the administration of public affairs; such as the election of public officers, or compelling them to proceed in matters within their jurisdiction, or public officers to perform duties imposed upon them, as to make a rate and the like. But in more recent times it has been extended to cases in which the rights of private individuals only are concerned. In such cases, the writ of Mandamus is passed for making railways, docks, bridges, improving towns, &c., &c., and, in almost all of these Acts, there are provisions directing the company obtaining the Act to do certain works for the benefit of individuals; such as substituting new buildings for others necessarily removed, making new communications in lieu of old ones, and other works of a similar nature. In the event of noncompliance with these enactments, the remedy is by mandamus. This mode of proceeding has been termed in Pandolfini, a case that was authoritative, the procedure therein has been very materially altered and amended by the Common Law Procedure Act, 1854, the proceedings being now assimilated as much as possible to those in an ordinary action.

The remedy hitherto afforded by this prerogative writ, in cases where the public were interested, has, by the same statute, been extended to cases in which private rights only are concerned. The plaintiff may claim in his writ the performance of the duty which the defendant is bound to perform. The claim must be repeated in the declaration, which must set forth sufficient grounds for the claim, and show that the plaintiff is personally interested therein; that he sustains or may sustain damage by the nonperformance of the duty, and in the event of noncompliance the party against whom the writ is directed has been demanded by him, and refused or neglected by the defendant.

Where judgment is given that a mandamus do issue, the court, if it shall see fit, besides issuing execution in the ordinary way for the costs and damages, may also issue a peremptory writ of mandamus, commanding the defendant forthwith to perform the duty to be enforced, which the defendant must obey; for no return, except that of compliance, will be made by the court, although time to return the writ may, upon sufficient grounds, be obtained.

If the defendant fails either to obey or to return the writ, two courses are open to the plaintiff. He may cause the defendant to be arrested; or, in lieu of proceeding by attachment, the court may upon his application, direct the act required to be performed by the writ to be done by the plaintiff himself, or some other person appointed by the court, at the expense of the defendant; and upon the act being done, the expense of such act and the costs of the suit, both by the court, who may order payment of the amount of such expenses and of the costs, and enforce payment thereof by execution.

MANGRO-TREE. [Manigreta.]

MANIHOT. [Japinha, S. 2.]

MANIN, DANIELE, a distinguished Italian politician and patriot, was born at Venice in 1804, the son of Pietro Manin, a respectable advocate. His grandfather, Lodovico Manin, bore the same name as the last doge of Venice, whose weak behaviour at the time of the extinction of the
ancient republic by Bonaparte (1807) had attached a certain discredit to the name. Young Manin, who from the first showed great abilities, was bred up to his father's profession of the law, and graduated as Doctor of Laws at the University of Padua at a very early age. He married in 1836, and shortly afterwards commenced practice as a lawyer. He had the reputation of being a man of letté,

The chief of his career was the Austrian rule and the general aspiration after restored liberty and independence for Venice. Though not affiliated to any of the revolutionary societies then existing in Italy, he often discussed with several intimate friends—especially Alexandre Zaccagnini, the 18th-century novelist and Francovich, Giacomo Tagliaparti—his dreams of native country, and the possibility of remedying them by insurrection or other means. Once or twice—as during the time of the excitement caused by the affair of the brothels Bandiera in 1844—these secret communings were on the point of bursting out into open action; but, on the whole, it was felt by the friends that no movement was practicable, and Manin continued in the ordinary exercise of his profession, varying it by occasional contributions on economical topics to journals.

As a speaker, he was distinguished for a logical, direct, positive, and incisive manner, different from the ordinary eloquence of his countrymen. As on several important public trials he acted a vigorous part in the liberal side, he came to be a chief of the Austrian government; and in the early part of 1848 he was imprisoned. But this year was to witness a change in his fortunes, and in those of Italy. On the 18th of March the spirit of insurrection with which the Venetians were inflamed was carried forth not only by Manin from Milan; the news of the expulsion of the Austrians from Milan acted immediately on Venice, and on the 23rd of March the Austrian commander of the city, Count Zichy, was obliged to surrender, and the republic was declared. It was at this time that Manin considered himself as a man born to lead. The progress of events was for a time complex—the fate of the Venetians being involved in that of the other Italians. "What we preferred," Manin afterwards said, "was to be independent, without being in a situation to be confederated with the other Italian states; but what we would have accepted was, to become a portion of one great kingdom comprising all Italy."

The war of Charles-Albert, the king of Piedmont, against the Austrians in the name of Italy, as a whole seemed for a while to give likelihood to the latter expectation. The Venetians, willing to show their trust in Charles-Albert agreed to the fusion of their little republic with Lombardy and thus to form a united Kingdom of Northern Italy. But the battle of Custoza having ended that dream, and restored Lombardy to the Austrian dominion, the Venetians again fell back upon their own resources and prepared for a separate defence. The republican standard of Manin was raised; a committee of three was appointed to carry on the executive government, Manin being the chief of the three; and the military command was intrusted to the Neapolitan general Pepé, who had thrown himself into Venice two months before, rather than obey the order that he should return to Naples. Though the Austrians kept up a blockade against Venice, it was not till March 1849, when the second attempt of Charles-Albert was brought to an end by the defeat of Nevaro, and when the Austrians were obliged to reconquer, then to be reconquered their lost territories in Italy, that the Venetians endured the full agony of the struggle. By that time the patriotic movement had been completely crushed in every part of Italy, a small town near the exception of Rome. The two republics of Rome and Venice were the sole remains of the insurrectionary work of the previous year; and against the one of these the French were mustering their power in conjunction with the Austrians and Neapolitans, and Manini's was signaled by them. Both republics behaved bravely. What Manini was to Rome, Manin was to Venice. From March 1849 he was invested with all the powers of the dictatorship. The definition of his power selected by him is one of the most gallant and obstinate in the history of Italy. He was on the 3rd of July that the French entered Rome; but Venice did not surrender till the 24th of August, after it had suffered a dreadful bombardment. With the fall of Venice the re-

subjugation of Italy was complete. The terms of the surrender were such that Manin was able to go safely into exile. He afterwards resided chiefly in Paris, supporting himself honourably. He died September 28, 1857.
most eminent anatomists. They give a feature to the herp-
etology of the middle portion of the secondary epoch. Now,
of the five marked genera constituting this group, as at present
determined, are: *Iguanodon*, *Hesperosaurus*, *Pelorosaurus*, and *Re-
nothosaurus*—to Dr. Mantell. Worthily then were the Wol-
ston Medal and Fund adjudicated to our lamented colleague in
the very-esteemed County History Society of Sussex; the late Edward Wed-
slowly, F.S.A. In the "Bibliotheca Zoologica et Geographi"
of Agamaist and Strickland, no fewer than sixty-seven works
and memoirs of various degrees of importance and length, are
enumerated as having proceeded from Dr. Mantell’s pen; to
these must be added his numerous antiquarian papers, and several
professional disquisitions.

**MARSH AND SERBOURQUE LOUIS VIEME DE MARECHAL DUC DE RAGUSE,** the son of
the Chevalier de Marmont, an old officer of distinction, was
born at Châtillon-en-Seine, on the 30th of July 1774. He
entered the army as an ensign in infantry in 1789; but
afterwards, on the death of his father the comte de Marmont,
who had been general, he was adopted, in 1792, to the Artillery School of
Châlons. Towards the end of that year he served in the campaign of
the Alpes, under General Montesquieu. He was present
at the siege of Toulon, December 1793; and having been
adjudged a 1st class of the Legion of Honour, he was
sent him, in 1794, to the Artillery School of Châlons.

For the great insur-
rection of the people, he was given a captain's
commission, as aide-de-camp, and a captain in the
campaign of Syria, in 1796; he was appointed commander in
Alexandria, and defended that city against the English
and Turks, in a season of famine and pestilence. When General
Marmont was recalled to France, on his return from Egypt,
August 22, 1799, General Marmont was one of the seven officers
selected to bear him company in his perilous enter-
prise.

During the crossing of Mount Saint-Bernard in the spring
of 1800, Marmont's plans for the conveyance of the guns
having been adopted, he superintended the entire transport,
and by his persevering efforts the passage of this important
arm was effected. He fought with much distinction at
the battle of Marengo, June 14, 1800, and was immediately after-
raised to a division. After the peace gained by this victory,
he was made inspector-general of artillery; he then applied
himself zealously to various reforms in the service, especially
for the accelerating of the transit of the artillery train.
All these improvements were sanctioned by the First Consul,
though the young military reformer was only in his twenty-
seventh year.

In the campaign of 1805, General Marmont was
present at the capture of Ulm, October 9, 1805; and he was
successively employed in the reduction of the province of
Syracuse. Henceforward he commanded armies. In 1806 he
was sent to command the army in Dalmatia, where he acted
as general-in-chief for several years. On the 2nd of October,
he was sent to the army in Greece, and at the battle of
9000 Montenegrins, Greeks, and other troops, sustained by a
second corps of 7000 Russians. During his occupation of
the duchy, Marmont carried out a beneficial system of public
works, including a great line of roadway, 210 miles in
length, for which useful improvement he received his title of
Duc de Raguse in 1808. When the campaign of Wagram
opened in 1809, Napoleon called this general to support his main army. Marmont took the field with a corps of 9000 infantry, only 300 cavalry, and 12 pieces of cannon. With this force, which had never before been seen in the campaign, he advanced against several severely contested engagements; and then encountering General G Giulay, at the head of 35,000 troops, posted on the Drave, compelled that general to retreat to Hungary. After these successes he joined Napoleon the day before the battle of Jena, on 6th July, 1806, and, in the action, and received his marshal’s baton for his conduct in that arduous engagement. This decisive victory being followed by the treaty of Vienna, the Austrian government made Marmont commander in the provinces of Dalmatia, Ragusa, and Croatia, with other adjacent lands, which Napoleon formed into a single state, under the title of the Illyrian Provinces, and placed them under the direction of Marshal Marmont as governor-general. In this high office he continued nearly nineteen months, giving the peninsular to supersede Marshal Massena in the command of the army of Portugal. Though independent in his command, he hastened to unite his army to that of Soult, placed himself under the orders of that eminent leader, and assisted him in relieving the fortress of Salamanca. On July 22, 1812, he displayed however many proofs of skill as a general before he retreated, nor did he leave the field until he and the two generals who succeeded him had been dis- solved by severe wounds. In the campaign of 1813 the marshal did not participate. He began the campaign of Silesia, took Dresden, and was present at Tautzen, May 20, 1813; at Dresden, August 26, and at Leipzig on the 16th, 17th and 18th of October. In this last battle he defended the village of Schonfeld, which was taken and retaken seven times. Eight of his generals were either killed or wounded in the action; four horses sank under him, and he was twice wounded.

His name appears again in almost every battle fought on the French soil, in 1814, for the defence of his country. He terminated this campaign, perhaps the most brilliant in his career, by the battle before the walls of Paris, on the 30th of March 1814. The enemy, consisting of Russians, Prussians, and Austrians, were more than four to one, yet Marmont maintained his post for several hours, not surrendering even when the heights of Montmartre had been taken, and the first Russian gun had begun to sweep the Boulevards within the city; and it was not till some hours after receiving a letter from his superior general, Hydro, authorising him to withdraw, that Marmont and Mortier called a council of general officers at an inn within the suburb of La Villette, when they agreed to the evacuation of Paris.

The Duc de Raguse entered the French capital on the 1st of March, and Marshal Marmont, on the 4th of April, after a short correspondence with Prince Schwarzenberg, stipulating for the retirement of the French troops into Normandy, with arms, baggage, and artillery, entered the allied lines, and thence marched to Verailles. It was this step, taken without the sanction of Napoleon, which afterwards drew down upon him so much odium.

The Duc de Raguse was now wedded to the cause of the restored dynasty. He accompanied Louis XVIII. to Ghent in 1815, returned to Paris with that sovereign after the battle of Waterloo, and was employed repeatedly both by that monarch and Charles X. in offices of great trust. At the outbreak of the July revolution in 1830, he was charged with the invincible duty of quelling the revolt, and having failed, became a second time the mark of almost universal obloquy. To satisfy the popular indignation, he was struck off the list of the French army, and exiled from France. He spent his years of banishment in visiting different countries, and in writing works of considerable extent on the history of Russia, Austria, and other states. Nearly twenty-two years after his disgrace, he died at Venice, on the 2nd of March, 1852, in his seventy-eighth year. The publication of his "Memoires," in 9 vols. 8vo., Paris, was completed in 1857.

MARRAST, ARMAND, who succeeded Carrel as chief editor of "Le National," was born in 1802, in the south of France. After being educated at the College of Pons- levoy, he went to Paris in 1827, and immediately con- menced his career of politics by writing pamphlets against the government. The pungent and playful humour of these light productions drew notice upon the author, and he at once made for himself a distinct position among the young men of letters. His name is associated with the first French political newspaper, "Le National," and the period of its editorship is marked by a notable display of that political energy that characterised his career. His wit and satire, and the vigorous logic of his brilliant brochures against Consisnisme.

In 1830 Marrast established the newspaper "La Tribune." It became the organ of the ultra-liberal party, and as such he was then sought after by foreign as well as French journals. It contained very bitter articles against the government of Louis Philippe, and the fines to which it was condemned, together with the law-suits attacking its defence, put an end to its publication after a few years. Marrast then published his celebrated pamphlet, "Vingt Jours de Secret," which pro- duced a great sensation, and much increased his popularity. Proceedings were taken against him by the ministry. He sought refuge in England, remained several months in London, and continued his daily journal "Le National," as his ability to "Le National," and married an English lady during his sojourn in this country. These letters were the origin of that long connection with Armand Carrel and "Le National," which afterwards gave to Marrast the influence he had over the public. He was an ardent supporter of the revolution of February 1848, a period of nearly twelve years, Marrast conducted that journal, and maintained him in the high position it had acquired under Thiers, its first editor, and then under Carrel.

During 1847, a series of exciting incidents rapidly followed one another, highly favourable to Marrast's satirical ability. At the same time, other events of the year, another, rumors of bribery and corruption among men high in office; next, these rumors were succeeded by frequent exposures or confessions; and lastly, came the scandal of assassination in the mansion of a great noble. The repub- lican journals made the most of these incidents, and "Le National" took the lead in denouncing the government and the court. The revolution of February, and the abdication of Louis Philippe followed. Pending the crisis of this event, the commune of Paris was, for the time, the representative of the people, and the government; and depictions visited Marrast, and received their instructions from him. His name was now on every tongue; and when Lamartine was placed by the rapid pro- gression of events at the head of the provisional government, Marrast, an arbitrary, after being on terms with Paris, was finally president of the National Assembly. This last office was limited by a new regulation to one month; but the urbanity of the new president, and his extraordinary influence over the 900 members in consequence of his ability, is calling them to order by humorous appeals, caused him to be re-elected several times. To him likewise was committed the task of drawing up the new constitution. But the republicans party soon found that Marrast was not adverse enough for them; they began to estrange him as a moderate, and his popularity fast declined. On the 15th of May 1848 the insurgents, headed by Barbès and Blanqui, forced their way into the Hôtel-de-Ville, their first cry being "Where is Marrast?" We must make in end of that soft-handed repub- lican!" But he had withdrawn for concealment to a private chamber which was not searched. After the insurrection of June, and the consequent dissolution of the Lamartine cabinet, Marrast retired into private life. We believe he still continued to "Le National," and long after being its editor, until the paper was suppressed by the government of Louis Napoleon. He died on the 10th of March 1832.

tract of marriage merely before the Superintendant Registrar, to have the ceremonies of the church or of their own persuasion added at any time afterwards. The object of this enactment is to permit the couple to satisfy their religious scruples which, after the merely civil form of the contract has been resorted to, may arise or be suggested to them.

(Mr. Kerr's ed., vol. 1, p. 464.)

MARRYAT, FREDERICK, was born in London on the 10th of May, 1792; was entered at Christ's Hospital, and received his education at Rugby; in 1810 he entered the Royal Navy, and was sent to America as a midshipman. Under this daring commander he was engaged in upwards of fifty actions, of more or less importance, off the French and Mediterranean coasts during the next three years. In one he was left for dead on the deck of a ship which he had boarded, and only recovered when a fellow midshipman, who had a grudge against him, touched his supposed dead body with his foot, and began to moralise in rather uncompromising terms on his premature exit from life. The reputation for gallantry and ability which he acquired under Lord Cochrane, was amply sustained by his conduct under other commanders. Lord Cochrane, on becoming Commander-in-Chief of the Channel Fleet, appointed him his midshipman. On four or five occasions he saved men from drowning by leaping overboard, at the risk of his own life. On one such occasion he saved the life of a son of William Cockburn, the Member for the Borough of Wimbledon, and an officer in his Majesty's Navy. On another occasion he leaped overboard in an attempt to save a sailor's life, he fond of their human and becoming the prelude of one of three sharks that were following the ship; and he had been given himself over for lost before he was picked up. In 1812 he was appointed to the post of Lieutenant on board the Esquile, whence he removed to the New Castle, sent under Lord George Stuart, to cruise off the American coast. He attained a commander's rank in 1813. In 1820 he commanded the Alliance, of 74 guns, the force which had been sent to the relief of St. Domingo, and which had been involved in the affairs of the French revolutionists. In 1822 he commanded the soldiership of 17 guns, and in 1825 the sloop of 18 guns, and was trusted with the command of the East Indies squadron.

Marryat was sedulously reared in the British navy, and of all English ships in the world, he could have been but of one of the Royal Society. His early life was spent in writing and for the most part in the factory of novel production. Captain Marryat was a Fellow of the Royal Society.

MARS, ANNE-FRANCOISE-HYPOLITE BOUTET, known as MADEMOISELLE MARS, was born in Paris on the 9th of February, 1778; her father being the actor Monvel the Elder, a French actor who had been appointed to the Théâtre-François, and who was known as Mars-Boutet. She appeared before she was ten years old in juvenile parts, and in 1803 she already filled in the Théâtre-François, what on the French stage are called 'les rôles d'ingénues.' She met with a generous patronage of Mademoiselle Contat, then the leading actress in comedy, and received from her the best training for the cast of characters which her early talents pointed out as her own. After she had made herself familiar with these parts of the young girl, she was induced, still directed by Mademoiselle Contat, to attempt 'les jeunes amoureuses;' in which character she succeeded to the first place, after the retirement of Mademoiselle Méfray and Lange in 1798. She was then twenty.

Her fine talent was very gradual in its development, nor did the public notice that she had actually appeared until 1803 that her first marked success had obtained. In that year the part of a deaf and dumb pupil of the Abbé de l'Épée, in the piece of that name, having been assigned to her, she played it with dignity, and grace in its performance, that from that night she took rank as one of the great comic actresses. Her talents rapidly increased under the influence of cordial encouragement. Her kind instructor, Mademoiselle Contat, took an active part in the stage in 1824; abandoning the inheritance of 'reprôts' to be divided between Madeleine Mars and Mademoiselle Lervard, which gave rise to a long contest between the rival stars. The former however soon distanced her in all competencies. She stood at the head of all French actresses in genteel comedy, gaining a new success in every new part, down to that of Mademoiselle de Belle-Isle, in Dumas's drama, which she played for the first time on the 2d of April, 1839, when she had passed the age of three-score.

You, although she never refused to take the leading characters in plays of the new school, and in each achieved a new triumph, she was to the last opposed to the modern romanticists, and generally required extensive changes to be made in her own parts. She was not at first blush beloved by the public, and at certain times embarrassed by her criticisms and strictures, and the latter, in his 'Mémoires,' has described some piquant disputes of this nature between the actress and the dramatists. She went on to adhere to her own, but her genius had already become so august, that none could rival her, especially in the comedies of Molitor. In the lady of fashion, in the coquette of the beau monde, every spectator felt the collected self-possessing, the fullness of attention with which she performed these characters. It was her resolves will and extraordinary abilily which alone kept alive a respect for the earlier dramatic literature in the house to which she belonged, when a dozen theatres and fifty modern dramatists were endeavouring to subvert it.

Those who have occupied the stage on the stage, can form no idea of the simplicity, the seeming artlessness, the graceful elegance of her acting; nor of the music of her voice, so distinct that the very letters seemed printed in it, nor of the exquisite expression of her smile. Her form was very fine, her gait easy yet majestic, her costume remarkably elegant and distinguished. She was one of the shareholders of the Théâtre Français, and her yearly rent from this source amounted to 40,000 francs; and, in 1816, Louis XVIII. settled on her a pension of 20,000 francs. The hotel in which she resided was one of the most celebrated foreign as well as native artists and literati, some of whom were daily to be seen paying their court to her. She was sedulously attentive to the critics and public in general, and was said to have been admired by all her performances. On the night of the 7th of March 1841 she appeared for the last time on the boards of the Théâtre Français, in the 'Misanthrope' and the 'Fausses Confidences.' It was of course a benefit night, and for the last time she performed the parts of Célimène and Araminte. She
died on the 30th of March 1847, her death having been accelerated, if not caused, by the habit of having her hair dyed every ten days. She left behind her a fortune of 800,000 francs.

MARSHESEA. The Court of the Marshalsea and the Palace Court were abolished by the statute 12 & 13 Vict., c. 101. Their procedure and the costs of actions therein had for some time before been the object of animadversion by the late Mr. Franks, but the Government has recently well founded, amounted to no more than the universal complaint of the costs incident to legal proceedings. The Palace Court had never before been reputed by Royal Commissioners to be one of the best in the metropolis.

MARSILÈCAZ, or RHIZOCARPE, Peppers or RHIZOCARPUS, a natural order of Aquatic Plants, with creeping stems bearing leaves, which are usually divided into three or more leaf-stalks, and that a circinate vernation. The fructification is produced at the base of the leaf-stalks, and consists of sporocarps and inflorescences inclosing clustered organs, which consist of antheridial and pistillidial cells. The germinating body has an ovate form, and occasionally a mammillate on one side, whence roots and leaves proceed. The species are all inhabitants of ditches or inundated places. They do not appear to be affected so much by climate as by situation; thus they have been detected in various parts of Europe, Asia, Africa, and America, chiefly being of the warmer and healthier regions. The species number about 20, the principal of which are—Platinaris, Marsilea, Azolla and Sulinaea. (Balfour, Class-Book of Botany.)

MARTIN, JOHN, was born at a house called the Eastland Ends, Haydon Bridge, near Hexham, Northumberland, on the 19th of July, 1789. His early ambition being to become a painter, his father, as the best way of turning his desire to profitable account, apprenticed him to a coachmaker at Newcastle (whither the family had removed) to learn herald-painting. Here however he only remained a few months; and, his inductures having been cancelled, he was sent back to Italy by his father in 1801. His Italian patron of Muss, the father of Charles Muss, who acquired some distinction as an enamel painter. With him young Martin removed to London in September, 1806, and soon after, not getting on very pleasantly in his master's family, took lodgings for himself; and, as he relates in some autobiographical notes contributed to the Athenaeum' (see 'Ath. for 1854, p. 246, to which we are indebted for the leading facts contained in this notice), 'at this time, by close application to studies, an inquisitive turn of mind, and though often subjected which has since been so valuable to me. I was, at this time, during the day employed by Mr. C. Muss's firm painting on china and glass, by which, and making water-color pictures, I was enabled to make a livelihood. In fact, my struggle was so hard, and the success so meager, that I was forced to give up painting and to earn my bread as an engraver. In 1843, I took up again painting as a means of livelihood, and I continued to work in this manner until the time of my death.'

His marriage stimulated him to aolder concre. He determined to paint large pictures, and by a month's application produced in 1812 his first work, 'Sphinx in search of the Waters of Oblivion.' Before it left his hands his hopes received a severe blow: he 'overheard the men who were to place it in the frame disputing as to which was the top of the picture, the back or the front. I made, however, the frame in the frame the top of the picture would not be again in danger of being taken for the bottom. It found a place in the Royal Academy Exhibition, and, what was better, a purchaser for ten guineas, in Mr. Manning, a bank director. He followed up his success by sending to the British Institution an 'Exhibition from Paradise,' and to the Academy in 1814 'Clytie,' a work which was hung in the ante-room, as it was also larger and more ambitious picture, 'Joshua conducting the Israelites through the British still-life exhibition, where the 'Joshua' was again exhibited the following spring, it was placed in a post of honour, and awarded the prize. Martin was excessively angry with the Academy for the treatment of his grand work, and the breach was never healed. He resolved never to have his works accepted by the Academy except engravings. This, as long as he lived, kept him from writing books as a candidate for membership, and as a necessary consequence, according to the laws of the Academy, he never received any academic distinction. With the picture itself, and the success it met with, he was however abundantly satisfied. "The confidence I had in my powers," Martin writes, "was justified, for the success of my 'Joshua' opened a new era to me. In 1816 I removed to a superior house, and had to devote my time mainly to executing some immediately profitable works; but in 1819 I produced the 'Fall of Athene;' and the art world was second to the attention it excited. The following year came 'Macbeth,' one of my most successful landscapes; then, in 1821, 'Belshazzar's Feast,' an elaborate picture, which occupied a year in executing, and was reserved the receiving of 3000l. from the British Institution.'

These works, and especially the 'Belshazzar's Feast,' were of a kind then quite new, and took the London public by storm. A sturdy opposition was raised; but for the time it was fruitless. The public was swelled into a tornado, no doubt loudly declared—and pretty widely believed—that a new era was opened to art, as well as to the painter's self; and the engravings quickly made the artist's 'austere style' familiar from one end of the island to the other. Now was he slow to follow up his success: 'The Destruction of Nineveh' in 1822; the 'Serenth Plague' and the 'Papian Bowser;' in 1824, the 'Creation;' in 1826, the 'Deluge;' and in 1828 'The Fall of Nineveh,' perhaps the most popular of all his pictures after the 'Belshazzar.' He was now, however, so much engrossed with engraving, and with various schemes for the improvement of London, and other engineering projects, that for a while his pencil was somewhat less diligently employed, and when he resumed painting in 1830 he discovered that the spell which had been raised over his earlier pictures indeed found admirers, but they were few as compared to those which greeted his earlier works, and infinitely less enthusiastic. Yet he went on to the last painting which he did; it was a large picture of a family portrait, that he painted long before he died, as having captivated the public eye. Thus during the last twelve or fourteen years of his live he painted—'The Death of Moses,' and 'The Death of Jacob,' 1838; 'The Eve of the Deluge,' 'The Assaying of the Waters,' 1840; 'The Celestial City and River of Life and Flame,' 1841; 'The Deluge,' 1849; 'Christ stilling the Tempest,' and 'Canute the Great, rebuking hisCouriers,' 1843; 'Morning,' and 'Evening,' 1844; 'The Judgment of Adam and Eve,' and 'The Fall of Man,' 1845; 'The Deluge,' 1846; 'Pharaoh's Dream,' 1847; 'Arthur and Zige,' in the Happy Valley, 1848; 'The Last Supper,' 1850; 'Valley of the Thames viewed from Richmond Hill,' 1851.

The last picture he exhibited during his life was a 'Scene in a Forest—Twilight' (1850). He was now engaged on a series of three grand paintings, illustrative of the 'Last Judgment,' which he fondly hoped would be his master-work, and he laboured steadily at these till a few weeks before his death. Then suffering under a paralytic attack he set out in the hope of the cure. He died at his house in Battersea, on the 9th of July, 1854, at the house of Thomas Wilson, Esq., he died February 9th, 1854. His remains were interred in the lonely cemetery of Kirk Bradden, on the Starng Road, a few miles from Douglas, where his father had been buried. He was the last of his race, one of Wraith,' and 'The Plaisir of Heaven,' have since his death been exhibited in London and the provinces. As might be expected from the nature of the subjects, and the circumstances under which they were painted, suffering under the infirmity of age, with mind and body both subdued, they are comparative failures, having all the worst faults and mannerisms of the painter's earlier pictures, and only few of their redeeming excellences.

Martin was not the original painter, and possessed a very considerable share of imagination; and in the expression of material grandeur and terror,—the vastness and might of nature, in contrast with the weakness and littleness of man,—he was eminently successful. At least until by repetition the conception had been rendered common-place and imnpressive, this was unquestionably the case; and the unparalleled popularity of his early pictures, while the manner was new, could be readily understood. But Martin did not perceive that his was a trick of style which would not wear. He kept on repeating the same subject, and he kept on with interminable vistas of buildings, piles upon piles, as buildings never could have existed in reality, and crowding the roads and fields with myriads of little insignificant figures. He added to this, as the evening approached, with flashes of jagged lightning or streams of dazzling sunshine; never advancing beyond a harash and niggling torch, or attaining to anything better than a crude and conventional system of colour. Seeing only two, or at most three, of his pictures, he might be pronounced a man of

gens; seeing all, while acknowledging his talent, it is
difficult not to feel surprise at his deficiencies of taste, ob-
servation, and judgment.
It has been said that during many years the subject of the
improvement of London occupied much of his time and thought.
As early as 1829 his ideas had taken a definite
shape, and he gave them to the public in a 'Plan for sup-
plying with pure water the Cities of London and West-
improving the western end of the metropolis,' and he continued
his labours in the north of England, and laboured earnestly at
himself heart and soul to the peaceful agitation, he had the
beauty to see within a few months no less than a
500,000
converts in Cork alone. Extending his sphere of action
he commenced a 'progress' through the west of Ireland,
where proportionate results were seen; wherever he went
his name was familiar, and the pledg
pledge of temperance were so numerous, that they could
only be kept in control by the military and police.
and the same results followed in all the towns which he visited
in Ireland. In 1837 he, with the aid of 
127 poor
law machinery, the Society was incorporated, and
and its articles of
existence were published in London, and the
ers were
insured that the agitation thus kept up constantly, solely by
himself, has resulted in a vast alteration in the quantity and quality
of the water supplied by the companies, and in the estab-
lishment of a Board of Health, which will, in all probability,
eventually result in the supply of wholesome water to the peace-
unging.
Amongst the other proposals which I have advanced
is my railway, connecting the river and docks with all the
railways that diverge from London, and apparently approved
by the Railway Terminus Commissioners, as the line
which the public is for the first time permitted to cross by
me, and which is described in their report; - the principle of rail adopted by the
Great Western line; the lighthouse for the sands, appropriated by
Mr. Walker in his Maplin Sand Lighthouse; the flat anchor
and pontoon which I recommended in 1825, and which,
I believe, have not been abandoned; the jetty at East
harbour and pier; iron ship, and various other inventions of
comparatively minor importance, but all conducing to the
great ends of improving the health of the country, increasing the
produce of the land, and furnishing employment for
the people in remunerative works.

MARTINSITE, A Mineral, which is composed of 91 per
cent. of chloride of sodium and 9 per cent. of sulphate of
magnesia. It comes from the salines of Hafhurst. (Dana,
Mineralogy.)

MATERIA MEDICA [Therapeutica, S. 2.]

MATH, THE REV. THEOBALD, the Apostle of
Temperance in Ireland, was born at Thomastown, county
of Tipperary, October 10, 1790. His father, an illegitimate
member of the family of the earls of Llandaff, died while
his grandfather, the fourth earl, and Theobald was enabled
by the kindness of the Countess of Llandaff and Lady Elizabeth
Mathew, to proceed to the academy of Kilkenny, and after-
wards to St. Patrick's College, Maynooth, where he remained
until he was ordained a priest of the Roman Catholic Church
in 1814. He was appointed to the parish of the Inch
and the neighbouring town, in which he resided seven years,
where his influence was great among the rich and the poor
alike; on his appointment to this mission he received from
the pope, Gregory XVI., the degree of D.D. with a dispensa-
tion enabling him to hold property. After the
abrogation of the Penal Laws and the freedom of the Press
which followed, the sufferings of the inhabitants of
Cork was the establishment of a religious society for
the purpose of visiting the sick and needy, on the model of the
societies of St. Vincent de Paul: this institution obtained
the approbation of the Right Rev. Poor-Law Commissioners
in 1854. About four years later he was requested to lend
his aid to a temperance association formed in Cork. He
joined the association and became its president; and devoting

Mehemet Ali, Pasha of Egypt, was born in the town of Cavalla, in Romii, about the year 1769. He began life as the keeper of a small shop in his native town; but having ventured into the army, he gained the rising of all the Albanian forces of the Albanian governor of Candia by his zeal in suppressing a rebellion of the pirates of that island. In 1799 he headed a contingent of 300 Caidian soldiers in an expedition to Egypt, where he conquered the Egyptian forces of the Ottoman ruler of the island of Candia by the French. Here he laid the foundation of his military renown and of his political ascendancy. On the evacuation of Egypt by the troops of the Emperor Napoleon I., the Sultan nominated, as viceroy of Egypt, Mohammed Khoeïrov; but the Mohammedan Khoeïrov, to save himself from the sexual influence, of which they had been deprived during the occupation of their country by the French, chose Mehemet Ali as their viceroy. In 1806 he was made Pasha of Cairo, to which in the following year was added the Pashalic of Alexandria, as a reward for his services rendered to the Ottoman Empire. No sooner however had he gained this pitch of power than he turned against his old confederates the Mamelukes—470 of whom he murdered in the citadel of Cairo in a violent assault on the Mameluke warriors. He passed through the country: an end was thus put to a turbulent and formidable race, which had kept Egypt in a state of anarchy and warfare for upwards of 400 years. After the destruction of the Mamelukes, Mehemet Ali made himself master of the country. He obtained the government of that part of the country, the revenue of which he considerably increased by raising the land-tax and the custom duties on its internal trade. In 1811 he was sent against the Wahabie, a fanatical sect of the Moslems, who had pillaged the holy city of Mecca and Medina, and whom he subdued after six years of constant warfare, and at a vast sacrifice of men and money. When the Greek insurrection against the Porte broke out, he offered to take part in the revolution; his fleet was sent to the Moros in the summer of 1834, under Ibrahim Pasha, who however was obliged to retire after the battle of Navarino in 1827. In 1830 the administration of the island of Candia was confided to Mehemet Ali; but he had greater schemes in his view. He aimed at obtaining possession of Syria; and pleasing as an excuse his desire to recover possession of some of the Egyptian possessions which had settled in that country, he invaded Syria, with a large army under Ibrahim Pasha, and soon reduced it to subjection. Syria as well as Egypt were entered upon as a kingdom in the third year of the reign of the viceroy of Egypt could not remain content with his own vice- regal territory; and peace was only made between the viceroy and the sultan [Mehmet II.] by the interference of the Great Powers in 1833. Sulyman Ali on his acknowledgment himself a vassal of the Porte. He remained in quiet possession of Syria as well as Egypt until 1838, when his nominal master, the Sultan, jealous and weary of the sway of so formidable a rival, sent an army and fleet to expel him from Syria; and when he found that this was impossible, he sought and obtained the co-operation of England and the other European powers. In the summer of 1840 the combined fleets appeared before the coast of Syria; in the autumn of the same year the Egyptian army was defeated near Beyrut, and both that city and Acre were captured, and Alexandria itself blockaded. Mehemet Ali was obliged to come to terms, and abandoned his claim to Syria, on condition of the Pashalic of Egypt being made hereditary in his family. He continued to administer the affairs of the country until September 1848, when he resigned the reins of government into the hands of his son Ibrahim Pasha, on whose death he passed to Abbas Pasha his grandson. Mehemet Ali himself lived only a few months after these changes. He died at the age of about eighty years. His wife and concubines he had six children; two of his sons he sent to Paris for the sake of education. He died at Cairo with great pomp and magnificence.

Mehemet Ali was tolerant in matters of religion to an extent rarely known among Mohammedans. His constitution was strong, his stature short; his features, though dark and stern, were animated and expressive. He was very ambitious, yet particularly sensitive to the opinion formed by others as to his public policy. His government has been extra-

vagantly praised by some writers; but it certainly was more rational, orderly, and enlightened than that of most of the combinations of the Porte. He augmented justice with partiality, established police and law-courts, abolished torture, and encouraged education. He did his best to remove the prejudices felt by his countrymen against the introduction of the arts and sciences of Europe; he even went further and made use of the machinery in his dominions, including a printing office for the publication of a periodical journal. He also formed schools and colleges for teaching the arts and sciences and of farming, which has since been followed by the Viceroy of Barcy in the liberal laws. His government was essentially despotic and absolute; and in order to support the expenditure necessary to maintain the institutions already mentioned as having been introduced by him, he was obliged to have resorted to a heavy increased taxation, and for his army to a enormous

Upon the whole, however, it must be admitted that the Albanian peasant was in his day a great benefactor not only to his country but to society at large. Gifted with an admirable talent for organisation, he was introduced to one of the most neglected and disorganised of countries the first conditions of a civilised state, order and security, to such an extent that it is said that a traveller, laden with gold, "could pass through the streets of Alexandria without an armed guard," even from the Taurus to the frontiers of Abyssinia, between sea and Nile and desert." In the administration of justice and the general management of his empire he introduced more of equity and settled principle than exists at the present time in many parts of the Ottoman Empire. He did his best to ennoble the sons of his subjects and to protect the Christian population. He not only encouraged commercial intercourses with Europe, but in a great measure created it; and by various enterprises of a grand and striking character, awakened that beneficial spirit of freedom by which the Ottoman nation had lain dormant in Egypt. He first called into life the cultivation of cotton, indigo, and sugar, which has since been pursued with increasing success—a large portion of the produce being sold in Europe and Asia, and the proceeds being used to support his army and navy. He determined to mean to build a fleet and to form an army trained after the European fashion. Such are the means by which the Albanian peasant, who only learned to read in his thirty-fifth year, and who often, but with his head in safety, became a powerful prince, who twice made the Ottoman Sultan tremble on his throne at Constantinople, and whose personal energy and public importance gave him a place among the potentates of the earth.

Melamin [Cherneur, S. J.]

Melampryne. [Cherneur, S. J.]

Melanospermum, or Fucalide (Harvey), the first subclass of the class Aceae. It consists of plants of an olive-green or olive-brown colour. "Eucratization monocious or dicious; spores olive-coloured, either external, or contained singly, or in groups, in proper conceptacles, each spore enveloped in a transparent skin (perispore), simple, or occasionally divided into several spores; anthidia, or transparent cells, filled with orange-coloured viviparous corporules, moving by means of vibratile cilia. It includes the following orders:

Fuscosporae. Spores contained in spherical cavities immersed in the perispore. [Fuscales.]

Sporoloinaces. Spores attached to external jointed filaments, which are either free or compacted together in knob-like masses.

Laminariae. Spores forming indefinite cloud-like patches covering the whole surface of the frond.

Dictyostilae. Spores forming definite groups (sori) on the surface of the frond.

Cordariaceae. Frond cartilaginous or gelatinous, composed of vertical and horizontal filaments interlaced together. Spores immersed.
Edoscopon——Fond aliform, jointed. Spores external.

Williamstown, originally. The advanced is but lower whilst for a

The MELISSIC is situated

MELILLA, a genus of plants belonging to the natural order Labiatea. It has anthrae approaching in pairs and forming a cross bursting longitudinally. The upper lip of the corolla flat, entire, straight; lower lip with 3 rounded nearly equal lobes; calyx membranous, bell-shaped, ample, variously lobed and toothed. 

M. Melittisphylum, Bastard Balm, has oblong, ovato, or slightly cordate leaves. The upper lip of the calyx with 2 or 3 teeth; flowers purple, with a white margin, or variegated in different ways, large, stem 1 or 2 feet high. M. grandiflora (Smith) has a height. They are both found in woods in the south of England.

MELKSHAM. [Whiteways.]

MELOSIRE, a family of Diastomes, formed by Kitting. The species are strait, not having a central opening on the secondary side. The stirrups are interrupted in the median line. It includes the genera Galionella, Melosira, Pediastrum, and others. Meneghini, in his 'Natural History of Diatomea,' makes the following critical remarks on this group:—

"The Melosira in general may be regarded as polytrophic associations of Cyclotella, and the comparison prevails principally in the second sub-genus. The distinction of the two sub-genera is also proposed by Hassall (Sphaerocysta, Melosira, Callolenas) ; but the specific names in the majority of this are at present given to the genus itself of a bishop; a corporation town with a mayor; the residence of the lieutenant-governor; and the seat of government.

The gold finding in the colony, which appears to continue without much diminution, attracts numerous emigrants to Melbourne, especially from Great Britain; but the population of the city is probably now more than 40,000. Vessels of 200 tons can ascend the river to Melbourne, larger vessels lie in Hobson's Bay. Williamstown, the port of Melbourne, is a small town built on a low sand-flat at Point Grillbrand, on the south side of the entrance of the river. There are some good houses. A railway connects Williamstown with Melbourne city. By means of a pier at Williamstown, having a communication with the railway terminus, bottles and goods may be landed and sent on to Melbourne.

MELDRUM. [Aberdeenshire, & 1.]

MELILLA, a sea-port town of Maroccon belonging to Spain, is situated 11 miles S. from Cape Ras-ad-Diir, or Tres-Focos, in 36° 8' 15" N. lat., 2° 56' 9" W. long., and has about 2000 inhabitants. The town stands on a peninsula about 40 feet above the sea, and united to the mainland by a rocky isthmus. Melilla is one of the Spanish presidios on this coast. It is impregnable on the land side, and towards the sea it is defended by large batteries. The town has large magazines and citadels, and small vessels can enter the harbour. The presidio of Peñon-de-Velez and Alhucemas, or Alhucemas, two strong fortified rocky islands between Cape Tres-Focos and Melilla, are also under the governor of Melilla. The Spanish garrison of Melilla numbers about 1000. The rest of the inhabitants are for the most part convicts and exiles. Melilla is said to derive its name from the Spanish word for honey, which is gathered of superior quality on the mountain slopes along this coast.

MELISSIC ACID. [Chemistry, & 3.]

MELITTA (Kirby), a name for a genus of Insects belonging to the order Hymenoptera, and to the tribe Meliffera of Latrille. The genus as originally constituted by Kirby embraced all the Honey bees known at that time. This genus is now split up into numerous smaller ones. Leach divides the Meliifera into two families, Andrenida and Chrysididae.

The Andrenidae include the following genera:

England trace Were works, of youthful child, describes them as the same organic condition, and hence arises a fresh doubt respecting the systematic value that has been ascribed to it.

In general we may also say, that in the *Melodram* the development of the lateral surfaces prevails over that of the primary ones, which we find finally to disappear in certain genera (*Pteridium, Podostea*), as well as in some species of *Melobesia* (variae, *orchidacea*), the increased length of the axes and the corresponding development of the primary surfaces: and it is to be observed, although the plan of the family the primary surfaces differ precisely as much in form as they do in the three preceding ones, yet we find in these the same organic character as in the greater number of the preceding ones. Consequently, the primary forrows or canals. The separation of one lateral surface or valve from the other, with the consequent dilatation of supero-lateral surfaces, which the primary surfaces exhibit before the duplication takes place (though verified to some degree in other genera, yet by the Art in its present state, better than elsewhere, represents an undeniable analogy with the reduplication of *Desminia*, which Brébisson distinguishes from the deduplication of *Diactinum*. The particular disposition of the internal surface of the lateral valves has never been ascertained, a centre, the enlargement of some articulations, and the dilatation of the interstitial ring, are isolated facts, which however merit particular attention in the pædax of our knowledge.

MENACANITE. [TITANIUM.]

MENDHUS. [MAIZE.]

MENDELSSOHN. FELIX MENDELSSOHN-BARTHOLDY, one of the greatest musicians of the present century, was born at Berlin, on the 3rd of February 1809. His father, who was the head of a great banking-house, on his marriage adopted the name of his wife's family in addition to his own. He had embraced the Lutheran faith, and his son was educated as a Lutheran. When he was in his infancy, his father removed from Hamburg to Berlin, where he resided till his death, enjoying a distinguished place in the society of the Prussian capital. He bestowed the utmost care upon the education of his son, who showed, at a very early age, singular attainments, not only in the art to which his genius especially directed him, but in various branches of literature and science. While yet a child, he gained the affection of Goethe, who was a friend of the family, and published letters in which astonishing man contains many touching expressions of his love for the youthful Felix and prognostications of his future greatness. He was even then remarkable for his amiable disposition and simplicity of mind; qualities which he retained unimpaired to the end of his too short life. As was in the case of almost every great musician—of almost every great artist: indeed of any description—Mendelssohn's genius showed itself even in infancy. He tried to play almost as soon as he could walk. His great talents received the best and earliest culture. Zelter, the friend and correspondent of Goethe, was his chief instructor in music, and his progress was almost as marvellous as that of Mozart. Indeed his first works, which were afterwards published, were in advance of anything till that time exhibited at an early tender age. His three quartets for the pianoforte, violin, and violoncello, written before he was twelve years old, are not merely surprising juvenile compositions, but masterly works, which continue to be constantly performed, and hold their place among the classical music of the age. He was in his sixteenth year when his opera, 'The Wedding of Camacho,' was produced on the Berlin stage, more, it has been said, from the wish of his proud and happy parents than his own, for the most moderately modest and always formed a part of his character. It was favourably received; but, as it betrayed some inexperience in composition for the stage, it was withdrawn by his friends. It was however published; and, though it is not generally known to the public, many copies of it have been sold, and it has been especially admired in Germany. The famous *Ferruginea* (M. ochracea, Ralfs), which he proves not to belong to the class of *Diactinum*.

"We shall find, as a character common to them all, the circular figure of the vertical section parallel to the lateral surfaces, of which the rayed disposition of the striae upon the lateral surfaces, we shall find repeated in the family of *Coscindotaces*, which, having the shield of a cellular structure, belong to the tribe of *Dioideae*. Perhaps we may suspect some *Melobesia* (*ulica, decussata, titrate*), to be furnished with the same organic condition, and hence arises a fresh doubt respecting the systematic value that has been ascribed to it.

In general we may also say, that in the *Melodram* the development of the lateral surfaces prevails over that of the primary ones, which we find finally to disappear in certain genera (*Pteridium, Podostea*), as well as in some species of *Melobesia* (variae, *orchidacea*), the increased length of the axes and the corresponding development of the primary surfaces: and it is to be observed, although the plan of the family the primary surfaces differ precisely as much in form as they do in the three preceding ones, yet we find in these the same organic character as in the greater number of the preceding ones. Consequently, the primary forrows or canals. The separation of one lateral surface or valve from the other, with the consequent dilatation of supero-lateral surfaces, which the primary surfaces exhibit before the duplication takes place (though verified to some degree in other genera, yet by the Art in its present state, better than elsewhere, represents an undeniable analogy with the reduplication of *Desminia*, which Brébisson distinguishes from the deduplication of *Diactinum*. The particular disposition of the internal surface of the lateral valves has never been ascertained, a centre, the enlargement of some articulations, and the dilatation of the interstitial ring, are isolated facts, which however merit particular attention in the pædax of our knowledge.

MENACANITE. [TITANIUM.]

MENDELSOHN. FELIX MENDELSSOHN-BARTHOLDY, one of the greatest musicians of the present century, was born at Berlin, on the 3rd of February 1809. His father, who was the head of a great banking-house, on his marriage adopted the name of his wife's family in addition to his own. He had embraced the Lutheran faith, and his son was educated as a Lutheran. When he was in his infancy, his father removed from Hamburg to Berlin, where he resided till his death, enjoying a distinguished place in the society of the Prussian capital. He bestowed the utmost care upon the education of his son, who showed, at a very early age, singular attainments, not only in the art to which his genius especially directed him, but in various branches of literature and science. While yet a child, he gained the affection of Goethe, who was a friend of the family, and published letters in which astonishing man contains many touching expressions of his love for the youthful Felix and prognostications of his future greatness. He was even then remarkable for his amiable disposition and simplicity of mind; qualities which he retained unimpaired to the end of his too short life. As was in the case of almost every great musician—of almost every great artist: indeed of any description—Mendelssohn's genius showed itself even in infancy. He tried to play almost as soon as he could walk. His great talents received the best and earliest culture. Zelter, the friend and correspondent of Goethe, was his chief instructor in music, and his progress was almost as marvellous as that of Mozart. Indeed his first works, which were afterwards published, were in advance of anything till that time exhibited at an early tender age. His three quartets for the pianoforte, violin, and violoncello, written before he was twelve years old, are not merely surprising juvenile compositions, but masterly works, which continue to be constantly performed, and hold their place among the classical music of the age. He was in his sixteenth year when his opera, 'The Wedding of Camacho,' was produced on the Berlin stage, more, it has been said, from the wish of his proud and happy parents than his own, for the most moderately modest and always formed a part of his character. It was favourably received; but, as it betrayed some inexperience in composition for the stage, it was withdrawn by his friends. It was however published; and, though it is not generally known to the public, many copies of it have been sold, and it has been especially admired in Germany. The famous *Ferruginea* (M. ochracea, Ralfs), which he proves not to belong to the class of *Diactinum*.
the national instrument, who are chiefly retainers of great families, and assemble annually in the Edinburgh theatre to concert the Sacred Harps, and who have on more than one occasion displayed the most brilliant company of the metropolis—a relic of Scottish feudalism still preserved. To the surprise of his cicerone, who merely wished to give him half an hour's amusement, Mendelssohn remained to the last, immersed in what he heard, and showed, at the same time, as sincere and cordial appreciation of the powers of the performers. Many years afterwards, the same friend heard the celebrated symphony in A minor (now called the Scottish symphony) performed for the first time in London, at a concert of the Philharmonic Society. Struck with the strains of Highland melody which characterise that piece—the festive dance, the gathering, the warlike march, the lament—he was about to make some remark to Mendelssohn, when he said: "I told you that the symphony is a fine orchestral piece too, 'The Isles of Fingal,' is full of the impressions made upon his mind by the wild and stormy shores of the Hebrides.

In the following year he was for some time in Italy; and two years afterwards he visited Paris. From thence he came a second time to London; and from that time, we believe, to the end of his life, there was scarcely a season in which he did not visit England. He began even then to feel that he was possessed of a country of his own; and thenceforward England became, as it were, his adopted country, and was associated with the most important circumstances of his artistic life. His treatment at that time by his own countrymen appears to have inspired him with different impressions. It has been said, that "the great cabals which were always at work against him at Berlin increased his dislike to that city so much as to induce him to leave it, as he then thought, for ever. He left Berlin for Leipzig, where he accepted the directorship of the famous Gewandhaus Concerts, and where he remained till the year 1844, when he was induced, by the pressing request of the King of Prussia, to return to Berlin.

The admission upon his glorious career as a composer of sacred music may be fairly ascribed to the committee of the Birmingham Festival; for he set about the composition of his first oratorio, 'St. Paul,' under the arrangement that it should be performed under his own direction at the festival of 1837. And it was so performed accordingly, having been previously produced at Düsseldorf and Leipzig.

The performance of this oratorio in the Town-hall of Birmingham on the 30th of September 1837, was an event memorable in the annals of music in England. It was got up by the two gentlemen whose names appear as the principal subscribers to the foundation of the Birmingham festivals of that town are distinguished. The impression which it made upon an immense assembly will long be remembered by those who were present. Mendelssohn was again in London in 1840, when the proceedings of the Festival were 'given,' or 'Hymn of Praise,' composed expressly for that festival, was performed under his own direction. This remarkable work, called a 'Sinfonia-Cantata,' in which the powers of vocal and instrumental music are equally employed in developing a grand design, had a great success, and like 'St. Paul,' was speedily reproduced in the metropolis, and at all the great music-meetings in the kingdom.

His third and last oratorio, the greatest of all—'Elia,' was also written expressly for Birmingham. Though he undertook it immediately after the production of 'St. Paul' in 1837, it was not performed till 1846; and during these nine years, it occupied a large share of his thoughts and his labours. When the time for its production drew near, he returned for a season at Berlin, and gave up every other occupation, in order to devote his whole powers to this work. The poem, in which the principal events in the life of the Hebrew Prophet are related in the language of the Bible, was constructed by Mendelssohn himself; and the English version, and executed and adapted the merits of this admirable skill by Mr. Barrowclough. The first performance took place on the 26th of August 1846, the performance being conducted by the author. The enthusiasm it excited cannot be described. It was probably the first time he had ever written to the order of the instrument, except the cloth, but the greatest oratorio given to the world since 'The Messiah': and this judgment has ever since been strengthened and confirmed, not merely by the opinions of connoisseurs and critics, but by the united voice of the British nation. The production of this immortal work was the crowning glory of Mendelssohn's career. He was again in London, in 1847, to superintend its performance at Exeter Hall by the Sacred Harps, and was four times performed there, and afterwards, under his own direction at Birmingham and Manchester. Soon afterwards he left England, never to return. His health had for some time been declining. Shortly after his arrival at home, he received a shock in the same week which slightly resembled him in character and talents, and to whom he was fondly attached. From this blow he never recovered. He was persuaded to visit Switzerland, where, living quietly in the bosom of his family, he regained his strength and returned home to his father's house, more than ever convalescent. But he soon relapsed, and at length sank under his malady, an affection of the brain, and expired November 4th, 1847, before he had completed his thirtieth year. He left many manuscript compositions, the greater part of which were placed in the hands of several eminent musicians, friends of his family, with a view to selection and publication; but none of them have been given to the world except a fragment of an Oratorio, entitled 'Christa,' and some scenes of a romantic opera. The suppression of all the others, some of which were known to be works of magnitude and importance, has excited much surprise and dissatisfaction.

In a sketch like this, it is impossible to speak in detail of Mendelssohn's music; but it is sufficiently known that his highest powers were displayed; and 'St. Paul' and 'Elia' will descend to posterity along with 'The Messiah' and 'Israel in Egypt.' Mendelssohn was exposed to none of the cares, struggles, and vicissitudes which genius is too often heir to. Happy in all his domestic relations, in the enjoyments and triumphs of his art, and above all, happy in a pure and blameless life, few men have had a more enviable lot than Felix Mendelssohn.
Penny elongated; nuts also more decidedly traumatic, the Whiting is obvious, in the jaws, fins, lateral line, colour, and vertebrae."

"M. deceptrix (Gadus deceptrix, Linnaeus), the Coal-Fish. This is decidedly a northern fish, but being a hardy species, is not without considerable range to the southward. It was the only fish found by Lord Mulgrave on the shores of Spitsbergen, and the fry, only 4 or 5 inches long, were caught with the trawls off the western coast of Davis's Strait, during the first voyage of Captain Sir E. Parry. It is found on the coast of the United States. It abounds in all the northern seas, and in the Baltic, and may be said to swarm in the Orkneys, where the fry all the months of summer and autumn. As an article of food it is more prized when small than when of large size. The flesh of specimens weighing from 15 to 20 lbs. is usually dried or salted. This fish has more provincial names than any other species, some of which only refer to it when of a particular kind of appearance, other names are given according to the physical state. Thus it is called Silcock, Pillock, Coth or Ruth, Harbis, Cudden, Sethe, Sey, and Oray Lord. In Edinburgh and about the Forth the young are called Pollieys, at Newcastle the fry are called Drysey, and when 12 inches long Pooldams. The Coal-Fish may be traced on the Irish coast from Waterford along the eastern shore to Belfast. When detained and well-fed in a salt-water pond they attain a large size, and are very bold and voracious. The head and body are elegantly shaped, the eyes large and dark, the skin silvery white and nearly straight; the upper part of the head and back above the lateral line almost black, much lighter in colour below the fins, becoming greyish-white with golden reflections on the sides and belly; pectoral, caudal, and dorsal all dusky-black; ventrals and anal fins greyish-white; the upper jaw rather the shortest, the lips tinged with purple red, the mouth black, the teeth very small, the irides silvery white, the papil black."

"M. eels (Gadus eels, Linnaeus), the Pollack. This fish is much less abundant on some parts of the coast than the Coal-Fish, but like that species is an inhabitant of the seas all round our shores. The fish is called Lythe in Scotland, but whether from its supple plant activity, or from 'it's a fish on which the Pollacks fish' is not decided. The Pollack is caught at Hastings and Weymouth, also in Devonshire, where it is sometimes sold as Whiting. When only 12 or 14 inches long it possesses a considerable portion of the flavour and delicacy of that fish. It is also caught along the Irish coast under the names of Pollack, Laith, and Lythe. The body is elongated; the upper part of the head and back above the lateral line olive brown, the sides dull silver white mottled with yellow, and in young fish spotted with dull red; the lateral line dusky, curved over the length of the pectoral fin, then descending and passing in a straight line to the tail; the dorsal fins and tail brown; the pectoral and anal fins edged and tinged with red or purple."

"M. eels (Gadus eels, Linnaeus), the Green-Cod. This fish was first added to the list of British fishes by Sir Robert Cullum, and if a distinct species, as some doubt if, is not only abundant, but has an extensive range. It is mentioned as an essay the longest; the maxillary bone terminal, and is taken on the coast of Scotland, the Isle of Man, and on the Cornish coast. By some it is thought to be the young of the Coal-Fish, and by others as the young of the Pollack. The northern naturalists, who have opportunities of making comparisons, are of opinion that there is no agreement of the specimens from the abundance of both, consider them as distinct species. It seems to combine in itself the colouring of the Pollack, with some of the peculiarities of the Coal-Fish, but appears also to be deeper for its length than either, though if the young of a large species, judging by analogy, that would not be the case. The subject in its present state is open to investigation, and invites the attention of those who are so located as to be able to obtain examples of both."

"MERTENSIA, a genus of Plants belonging to the natural order Boraginaceae. It has a calyx in 5 deep segments; corolla bell-shaped, with a short thick cylindrical tube with 6 minute protuberances in the throat; stamens inserted beyond the throat; filaments elongate; style simple; nectaries smooth, inflated, rather drupaceous, attached laterally near its base by a flat stalk; seeds free."

"M. maculata is a prominent branched stem; leaves ovate-rounded, with a short acicular appendage from the abaxial, glabrous, fleshy, glaucous; nuts smooth; flowers in racemes, purplish-blue; protuberances in throat of the corolla yellow; leaves with a flavoured resembling that of oysters; nuts free, forming a pyramid longer than the calyx; pericarp membranous; seed smaller than the cavity. It is found on the northern seashores in Great Britain."

"MERULA. [Blackbirds.] MESACONIC ACID. [Chemistry, S. J.]

"MESITINE SPAR, zinc or iron carbonate of iron and manganese. It occurs in yellowish rhombohedrons. Its hardness is 4.0, and its specific gravity 3.0 to 3.6. It includes much that is called Rhomb-Spar, or Brown Spar, which becomes rusty on exposure to the atmosphere."

"MESITYLOE. [Chemistry, S. J.]

"METACETONE. [Chemistry, S. J.]

"METEOROLOGY. To the article in the 'Penny Cyclopaedia' on this union of sciences applied to the investigation of the better understanding of the phenomena of the air, the meteor, and the heavens, may now be added some account of two or three important subjects, our acquaintance with which has recently been greatly improved."

"M. following is a condensed statement of the present condition of knowledge upon these subjects, which are connected in a remarkable manner with cosmical science, and with almost every department of physics and of the study of inorganic nature. It includes the subject of the meteor and comets, and the interrelation of a branch of physics with the study of which little attention has yet been given—the explanation and interpretation by means of our present knowledge, of the numerous relations of such phenomena which occur in ancient history, both classical and medieval, and the statements in the popular historical literature of more recent periods.

The spaces through which the bodies of the solar system and the planets pass extends about the universe by celestial bodies comparatively minute, but in number incalculable; which, in common with the smaller true planets of the system have received from certain astronomers and physicists the appellation of Asteroids, or minor planets, which have the same origin and the same ancient origin of any luminous object seen in the heavens. These smaller asteroids, when they approach within a certain comparatively small distance from the earth, are, or subsequently become, the objects termed shooting-stars, fireballs, and igneous meteors; new species of phenomena being successively presented by them as they come nearer to the earth's surface, and especially in many instances, in consequence of their finally passing through a great extent of the atmosphere in an oblique direction, so as to experience the effects of its increasing density, both physical and chemical, throughout a trajectory of great length. But in this general statement it is not pretended to deny that objects and phenomena very different in their origin and nature, as well from each other as from those now understood, may probably be included also under the popular or only half-scientific designations of meteors and shooting-stars."

The appearance of these meteors is in many cases attended or accompanied by a red or metallic fire, or solid objects, either stones, metallic iron, or in some cases both mingle together, in the same black, forming a series of bodies collectively termed Meteorites (or Aerolites, 'Penny Cyclopaedia'), consisting, mineralogically, of two principal groups, graduating into each other: one of these the Iron-Cast, the other the Iron-Ball.

The visible meteor, when observed at those distances which must be within the atmosphere, and possibly indeed when at much greater, must consist of flame, or gaseous matter in an ignited or incandescent state, and undergoing combustion, but arising, as may be inferred from Sir H. Davy's re-
searches on flame, not from the combustion of matter which under ordinary circumstances can exist in a gaseous state at the surface of the earth, but from that of matter which is there solid, consisting, doubtless, of the metallic or other combustible bases on which it is composed. Among these it may be remarked are sulphur and phosphorus, both which Davy particularised as capable of combustion in air rared to a degree equal to that of the regions of the atmosphere in which meteors had been observed to display their tracks. The fact that with this concentration of matter upon this circumstance, as meteors contain other combustible bases which very probably have the same property, including the metal magnesium, an element of almost every meteor, it follows that in some cases the intense white light of the head or body and proximate portions of the tail, to the red light of the distant and extreme portions of the latter, being attributable to the cooling down of matter during its course, and in proportion to its distance from the most intensely heated part of the meteor.

It would appear, both from theory and observation, that the figure of the meteors must approach in their course that of an oblique cone, and that of the solid of least resistance. The meteorites which fall, or are cast down from them, when unbroken, especially those consisting of metallic iront, retain approximately the form which had thus been imparted to the meteorites of which they were the nuclei, by the resistance of the air—a form retained, in the case of the more perfect volcanic bombs, and which they have received from the same cause. These effects of the resistance of the atmosphere to the meteor's motion were first pointed out by Mr. Babbage.

The persistent track or trail of less vivid light often continuing to be seen for several minutes, or for a considerable fraction of an hour, or even for more than an hour, after the disappearance of the meteor itself, must be attributed to the deposition in the atmosphere, in the meteor's path, of a kind of beam of finely-divided solid matter,—mingled probably with vapour, and no doubt in part produced by the condensation of vapour,—resulting from the combustion proceeding in the meteor, and the particles of which, being originally deposited in the form of minute globules, were afterwards carried to preserve, during their slow and uniform descent in the tranquil regions of the air, where they originate, the aggregate form in which they were deposited; while the low conducting power for heat of the rare atmosphere permits them to retain their high temperature and consequent luminosity for a comparatively long period of time. The continued action of gravity, and the disturbing agency of currents in the lower regions of the atmosphere, will, however, eventually convert the at first rectilinear beam into a more or less curved and waved figure, and at length produce the serpent of fire of the superstitious ages, accurately reproduced in the case of the meteor of the 7th of January, 1856, as witnessed at Tunbridge Wells, and reported by a subscriber to the Royal Meteorological Society, on the 10th of March, 1856. These views are supported by reference to telescopic observations of the trails, particularly by those of the late Professor Piclet, of that left visible for seventy or eighty minutes by the meteor seen in France and Switzerland on the 15th of May, 1811, the most luminous part of which "did not appear to be continuous, but composed of distinct and separate particles."

The production, continued, general change of form and decomposition of these trails, may be familiarly, but correctly, illustrated by comparison with the similar succession of phenomena characterising the trail of smoke and soot issuing from the funnel of a steam-ship during its progress in its course; in which case the beam of smoke has been seen to be a line more or less curved separated from flame and smoke, and often several miles in length, becomes a persistent trail, and gradually changes into a waved or serpentine form. In many cases the trail of a meteor must have been originally a cylindrical beam, constituted as now explained, having a diameter of many hundred yards (equal to or greater than that of the meteor itself), and a length of many miles, deposited, in an inclined direction, at heights of some miles above the earth's surface. An objection founded on the assumed solidity of the particles, and the considerable specific gravity which must be attributed to them as results of the combustion going on within the meteors, which, it might be inferred, are inconsistent with the meteor's appearance; but this objection has once over by the experiments of Professor Stokes upon the effects of the internal friction of fluids (noticed in the concluding division of this article) applied to the common metal of the atmosphere, in a fluid of widely-different specific gravity, and to that of the suspension in the air of the minute globules of water constituting the cloud. The trails of meteors are suspended like the clouds, though, at first, probably, in higher regions of the atmosphere, and like them they consist of excessively minute particles, which, as in all probability their dimensions will be very nearly the same in all directions, may be regarded as spherules also, and will, consequently, be suspended temporarily, like the globules of smoke in the atmosphere, by the force of gravity from the adjacent air, as the result of the enormous arising from the internal friction of the air. The degree in which they partake of the projectile motion of the meteor itself, will also tend to their longer suspension, by converting the state of the meteor's considerable specific gravity would cause into an oblique curvilinear descent.

The two great causes of all the phenomena now described, are evidently the motion and the heat of the meteors. The origin of the former is doubtless involved in that of the production of matter in space, and the latter, in the constitution of the earth and its satellites, a subject noticed below. Dr. Chladni, the earliest philosophical investigator of the subject of meteors and meteorites (as a whole), and in later times Sir H. Davy and Sir John F. W. Herschel, have ascribed the heat to the compression and friction of the air, resulting from the enormous velocity of from six to thirty miles in a second, or more, of the meteors, supposed to be solid when they enter the atmosphere. Still more recently, in a paper read before the Royal Society on the 26th of June 1856, Dr. Johnson and Professor William Thomson have inferred from their own experiments on the thermal effects of fluids in motion, to which those of solids carried through fluids must be equivalent, the great probability that meteors really acquire all the heat they manifest from the friction of the air.

In the present state of chemical and meteorological science, it is unnecessary to enter upon the question of the origin of meteors and meteorites further than to urge, that, the computed enormous magnitude of the former,—the actual diameter of some exceeding that of the earth by many hundreds of miles, while in some instances its dimensions must probably be expressed in miles,—their planetary velocity,—and the pregnant fact that they give out a more intense light, and are visible for many minutes, than any of the known products of nature, and that the combinations of characters explicitly claimed by the writer of this article for the particular meteors from which meteorites have been observed to descend, as well as for many, if not all of those from which they are not known, must at once disprove nearly all the hypotheses which have been framed specifically to explain the origin of meteorites; and especially, among others, that of their projection from lunar volcanoes. The cogency of this argument will remain essentially unimpaired if it shall be found, according to recent suggestions, that the supposed enormous mass of meteoric matter is, in reality, far less than that hitherto ascribed to them. The problem of their origin must, in fact, be regarded as the same with that of the origin of the greater asteroids and planets themselves.

It is right to state that Mr. P. P. Miers, who has given much attention to the subject, is of opinion that there is a distinction between luminous meteors and those from which meteorites have fallen; an opinion which, so far as the (apparently) smaller meteors, called shooting-stars, are con-
cerned, he shares with the American Professor Olmsted, and others. Mr. Greg is the author of a valuable essay on meteorites, entitled, 'Observations on Meteorites or Aéro-

lites, considered Geographically, Statistically, and Cosmically; accom-panied by the Catalogue of meteoric falls.' It was first published in the 'Philosophical Magazine' for November and December, 1854, and in a separate form in November of the following year.

Globules of sand, and other deposits which have been enunciated in this article, have resulted from long attention to it by the writer. Others will be found, together with an invaluable assemblage of facts, in Arago's 'Astronomie Populaire,' liv. xxvi., 'Mémoires Comptes,' tome iv. p. 181—392; and also in the reports on meteorites annually issued for the years past to the Reports of the British Association, by Professor the Rev. Baden Powell.

The last recorded fall of meteorites appears to have taken place in 1857, on the 28th of February, when two large stones fell at Parnall, in the Madura district, Madras, as related by the Rev. H. S. Taylor, in a communication to the Asiatic Society of Bengal.

The purely physical history of the subject having now been generally considered, we may proceed to notice the manner in which the extraordinary relations produced in former times, of the appearance in the sky of blazing torches, sceptres, bundles of rods, fiery swords, trumpets, and other objects, may be represented in a more rationally known type of meteoric phenomena. This subject belongs to a field in the history of science and literature, hitherto but little cultivated. It may be elucidated by examining the figures and accounts of such appearances which are given in the works of old writers, especially of the most eminent and learned authors of ancient times, and of the present, and also by Ambrose Parey, and comparing them with similar phenomena as witnessed in more modern times, and depicted by observers whose only object was to represent the actual constitution of the luminous appar-

ances. The circumstance that from the enormous rapidity of the meteor, all the visible phenomena (except the persistent train) would have been seen and have ceased to appear within the limits of a few seconds of time (so that in all cases the figures have been produced from the mere eyes alone), which must have led to the representation of many appearances as simultaneous that in reality occurred in suc-

cession, and the manner in which during the transit of the meteor, impressions on the retina of past phenomena must have been mingled with those actually present, have led to the production of many of the singular representations that are extant. It would not be difficult to trace the mental pro-

cess by which natural objects, thus witnessed for a few seconds, may be confounded and prepared for by the mind, and prepared for by the mind, and for, we may even be eluded by reference to the great meteor of 1788, which ex-

changed the ringed sceptre of the medieval figures, the rings on the shaft being manifestly the smaller meteors, the production of which is the first visible result of the explo-

sion, seen as projected upon the tail of the parent meteor; other either, as is evidently the fact in many instances, the appearance of the train in the case of the meteors can be accounted for on account of the blinding upon the retina of the observer of past and actual appearances. The fiery sword dipped in blood is the meteor in its normal form, at the middle of its visible course, the distinct part of the tail shining with red light, being cooled down to the temperature of simple igni-

tion, as already indicated. In a similar manner, the bull's head, flying-eagles, and other monstrous appearances may be consistently explained, care being taken, when the authorities peremptorily assert the phenomenon, to be convinced of the fact by the evidence of the eye.

Clouds. The most recent view of this subject, apparently only one simple, but which really involves a variety of physical principles, is that of Sir John F. W. Herschel, stated in the following terms (Encyc. Brit. Ed. 8, vol. xiv. p. 626):

"When the sun shines on a cloud, which absorbs its heat, the cloud itself is necessarily partially evaporated, and the vapour by its levity tends to produce an upward current, and thus to counteract the effect of gravity. The globules of which it consists. A globule of water 1-4000ths in. in diameter, in air of five-sixths of the density on the surface, or at the height of about 6000 feet, would have its gravity nearly equal to its buoyancy; and the vapour which has been prepared for by thought. be served of cloud during the night. It is more than probable, however, that, when not actually raining, cloud is almost in process of generation from below, and dissolution from above, and that the moment this process ceases, rain, in the form of 'flurries,' commences. In a word, a cloud in general would seem to be merely the visible form of an aerial space in which certain processes are at the moment in equilibri,

um and all the particles in a state of upward movement.

To this, influence must be required but an adequate estimate of the effects of the 'fric-

tion' and the 'drag,' which are supposed not to exist. But it appears to have escaped the attention of Sir J. Herschel, that Professor Stokes had already shown that the internal friction of the air, together with the 'drag' which it occasions, is itself one of the causes— in his opinion, indeed, the main cause,—of the suspension of the clouds. As this particular subject is new, and (as we have seen in the previous division of this article, with respect to the force of gravity) of great importance in meteorology, we shall treat it at some comparative length.

Clouds consist of an aggregation of separate minute globules of water; and the resistance to such a globe would be extremely great with its surface almost wholly on the cause just stated. "Since the index of friction of air is known from pendulum experiments, we may," Professor Stokes observes, "easily calculate the terminal velocity of a globule of given size, neglecting
the part of the resistance which depends upon the square of the velocity. The terminal velocity thus obtained is so small in the case of small globules, such as those of which we have been speaking, that even if, as is generally believed, suspension of the clouds does not seem to present any difficulty. Since in the case of minute globules falling with their terminal velocity the part of the resistance depending upon the square of the velocity is quite inconsiderable compared with that part which depends on the internal friction of the air, it follows that the pressure equal in all directions in air in the state of motion [which according to the common theory of hydrodynamics, it would be], the quantity of water which would remain suspended in the state of cloud would be enormously diminished.

To render this view of the subject complete, and to explain the value of the last observation, it must here be stated that Professor Stokes had before shown that the fundamental assumption of hydrostatics and hydrodynamics, that the pressure of a fluid is equal in all directions, though fully justified by experiment in the case of a fluid at rest, is not true in the case of a fluid in motion. The viscosity attributed to water by DuBois, and the inherent property "analogous to that of viscosity in liquids," ascribed to elastic fluids by Capt. (now Major-General) Sabine, from their respective positions, Dr. Jones上下文中的独立性是不正确的。Professor Stokes has demonstrated that the resistance of the fluid, whether liquid or gasous, is proportional, not to the surface, but to the radius of the sphere, and consequently the quotient of the resistance divided by the mass,—in other words, the accelerating force of the air—will be in a higher power of the radius than must diminishes, than if the resistance varied as the surface: on which principle the suspension, or proximate suspension, of the particles or globules depends. When the downward motion of a globule is so slow, that the part of the resistance which depends on the square of the velocity may be neglected, the terminal velocity of a globule of water forming part of a cloud may be determined. For a globule the one-thousandth of an inch in diameter, we have the velocity 1:933 inch per second. When the same area at the opposite end of an inch in diameter, the terminal velocity would be a hundred times smaller, so as not to amount to the one-sixtieth part of an inch per second.

The amount of that part of the resistance which varies as the cube of the velocity, and which is the only kind of resistance that could exist if the pressure were equal in all directions, for the velocity 1-933 inch per second, is not quite the one hundredth part of the weight; and for a sphere only the one ten thousandth of an inch in diameter, the ratio of the resistance to the weight would be ten times as small. Both these proportions, it is manifest, are quite insignificant.

The conclusion thus arrived at by Professor Stokes as to the cause of the suspension of the clouds, illustrates in a remarkable manner the connection of different branches of science. It is an application by him of the theory of internal friction, as applied to the ball pendulum, and verified by recorded experiment, and at the same time a continuation of his memoir 'On the Effects of the Internal Friction of Fluids on the Motion of Pendulums,' published in the Transactions of the Cambridge Philosophical Society,' vol. ix. The erroneous extension of the fundamental law of hydrostatics has been discussed by him in a paper 'On some Cases of Fluid Motion' inserted in the preceding volume of that work.
schools of the Oratory in his native city. Father Respighi, a priest of that congregation, observed the remarkable talents of the boy, and saved him for literature. He was removed to a higher school—one of the so-called 'Scuole Pic' of Bologna—and eventually to the archiepiscopal seminary, where, after completing the usual course of letters, philosophy, divinity, and canon law in the university, he was admitted to priest's orders in September 1797. Of the details of his progress in the study of languages during these early years no accurate record is preserved; but it is known that he acquired the principal modern languages, Greek, Latin, Spanish, French, German, and Swedish languages. In September 1775, at the early age of twenty-two, he was appointed Professor of Arabic in the university, and commenced his labors in the December of that year; but he did not long enjoy what would have been a most congenial office. On the annexation of Bologna, as one of the papal legations, to the newly established Cisalpine Republic, he refused to take the oath of the new constitution, and was set aside from the exercising of his functions. The conflict between Pius VII. and the first consol, the ancient constitution of the university was restored. In 1803 Mezzofanti was named to the higher-professorship of Oriental Languages, and became assistant librarian of the public library of the city. The study of Oriental Languages, however, being suppressed in 1806, Mezzofanti was for some years reduced to great distress, and became dependent for his own maintenance, and that of the orphan family of his street, mainly upon the casual income derived from private tuition. The elder brother of the late Archdeacon Hare is said to have been one of his pupils, and a living English cousin received lessons in English from him at a later period.

But for Mezzofanti steadily followed in private what had become his engaging pursuit—the study of languages. A letter of his, dated in 1804, to the celebrated Orientalist John Bernardo de Rossa, whose personal acquaint- ance of his situation, during his residence in Rome in 1806, inclosed a composition in twelve languages, which he submitted for the judgment of his correspondent; and before 1812 his reputation as a linguist had become thoroughly established. The well-known Pietro Giordani, in several of his letters to his friends, calls him "the divine Mezzofanti," and declares that his skill in living and dead languages entitles him to be regarded as "a man of all ages and all nations." The war of which Northern Italy was so long the field had afforded and Mezzofanti many opportunities of extending his stock of languages. He was attached to the Legation of Bologna, to which he was attached as volunteer chaplain, to be met—among the invalids of the Austrian, Russian, and French armies—Germans, Hungarians, Bohemians, Welsh, Spaniards, Poles, and Poles. In the desire to offer these sufferers the consolations of religion, partly from his love of the study itself, Mezzofanti laboured assiduously to turn these and all similar opportunities to account; and several instances are recorded in which, without the assistance of a grammar or dictionary, he contrived to establish a mode of communication with a stranger who was utterly ignorant of every language except his own, and eventually to master that language sufficiently for all the purposes of conversation. He has kept an account of this mode of study during these years, which is not a little curious and interesting. "The hotel-keepers," he says, "were in the habit of notifying to me the arrival of all strangers at Bologna; and I never hesitated, when anything was to be learnt thereby, to call upon them, to interrogate them, to make notes of their communications, and to take lessons in the pronunciation of their several languages. There were a few learned Jesuits too, and several Spaniards, Portuguese, and Frenchmen, from whom I received valuable assistance, both in their own and in the learned languages. I made it a rule to learn every strange grammar, and to apply myself to every new dictionary that came within my reach. I was constantly filling my head with languages, each to a very low degree, passed through Bologna, I tried to turn the visit to account, either for the purpose of perfecting my pronunciation, or of learning the familiar words and turns of expression. Nor did all this cost me so much trouble; for, in addition to an excellent memory, God had gifted me with remarkable facility of the organs of speech."

In the year 1815 Mezzofanti was appointed assistant librarian of the university; in 1816 he was reinstated in his professorship; and in 1817, he was made a canon. From this period, especially after the peace, his reputation rapidly extended. Every visitor of Bologna related fresh marvels regarding his prodigious attainments. Tourists from every nation, whether of Europe or of the East, united in representations of the knowledge of the learned man. St. Stewart Rose, in 1817, reported him as reading twenty languages, and speaking eighteen. Baron Zach, in 1820, set down the number at thirty-two. Lord Byron, about the same time, pronounced him "a walking polyglot, a master of thirty languages," and the Lady Morgan saw him, in 1821, common report described him as speaking no less than forty languages; but when she inquired from himself the truth of the report, he replied that he had only gone over the outlines of that number. M. Molbech, a Danish traveller of the year 1820, reports the number of his languages at "more than thirty," and testifies to his speaking Danish "with almost entire correctness." French, German, Spanish, Polish, Russian, Greek, and Arabic, are the languages most commonly spoken by Mezzofanti with regard to their own, but also to many other languages.

During all these years—except a short visit to Pisa, Leghorn, Florence, and Rome—he had resided altogether in Bologna, though invited to some of his friends to travel in Europe. From Paris to Vienna, and from Vienna to Rome. At length, having come to Rome, as a member of the delegation sent by the Bolognese to offer their submission to the pope, Gregory XVI., after the revolution in 1821, he was induced by the pope to settle permanently in Rome, and to accept a prebend in the church of St. Mary Major, which was soon after exchanged for a canonry in St. Peter's; and, on the promotion of the celebrated Angelo Mai, then keeper of the Vatican Library, to the secretariatship of the Propaganda, he was appointed in the important charge of the Vatican. He held this office till 1838, in which year, conjointly with Mai, he was elevated to the cardinalate.

Mezzofanti's residence in a great centre of languages, such as Rome, and especially the facilities of intercourse with the various races represented in the college of the Propaganda, gave a new impulse to Mezzofanti's linguistic studies. The reports of his visitors at Rome are still more marvellous than those of the Bolognese period. An eminent German scholar, Herr Guido Görres, who had much intercourse with him in the year 1841, writes thus: "He is familiar with all the European languages; and by this I understand not only the ancient and modern languages of the second class, such as the Greek and Latin, or the Italian, French, German, Spanish, Portuguese, and English—his knowledge extends also to the languages of the second class, viz., the Dutch, Danish, and Swedish—to the languages of the third class, such as the Slavonic—Russian, and Norwegian, as well as the Hebrew, the Arabic, the Syriac, the Samaritan, the Chaldean, the Sabae—I may even add, with the Chinese, which he does not only read, but speaks. Among the Hamitic languages, he knows Coptic, Biblical, Abyssinian, Amharic, and Anglesian."

What is especially remarkable is the facility with which the learned man was gifted by Mezzofanti is, that his knowledge of each among this vast variety of languages was almost as perfect as though his attention had been devoted to that language exclusively. The method of pronunciation, of course, was his great study, and the language faculty in describing him as speaking in each language thus with the precision, and in most cases with the facility of a native. His pronunciation, his idiom, his vocabulary, were alike unexceptionable. Even the familiar words of every day language were at his command; and in each language he was master of all the leading dialects, and even of the provincial peculiarities of idiom, of pronunciation, or expression, in
French, he was equally at home in the pure Parish of the Faubourg-St.-Germain or in the Provençal of Toulouse. He was a fluent and agreeable conversationalist, master of the Black Forest, or to the classic vocabulary of Dorothea; and he often amused his English visitors by specimens of the provincialisms of Yorkshire, Lancashire, or Somersetshire. With the literature of these various countries too he was well acquainted. He knew the great authors in their respective languages; and his remarks are described as invariably sound and judicious, and exhibiting careful and various reading, often extending to departments with which it would never be supposed that a foreigner could be familiar. A Dutch traveller, for instance, Dr. Wap, was surprised to find him well acquainted with his own national poets, Vondel and Cats; a Dane, with the philological works of Bask; a Swede, with the poetry of Olof Hjelm; a Greek, with the characteristics of the poetry of Me?l; and an English gentleman was astounded to hear him discuss and criticize Hudibras, of all English writers the least attractive as well as the least intelligible to a foreigner. He was in the habit too of amusing himself by metrical compositions in the various languages which he cultivated, and often wrote for his visitors a couplet or two in their native language as a little momento of their interview. Dr. Wap, the Dutch traveller just referred to, speaks in his diary of having been entertained thus by Mezzofanti replied to a sonnet which Dr. Wap had addressed to him; and the well-known Orientalist, Dr. Tholuck, having asked Mezzofanti some memorial of his visit, received from him a Persian couplet after the manner of Hafiz, which he was (although not without some delay) during Dr. Tholuck's visit.

After his removal to Rome, although he had already passed his fiftieth year, he added largely to his stock of languages. His most notable acquisition during this period was the Spanish, which he acquired (partly at the Chinese College in Naples, partly among the Chinese students of the Propaganda) in such perfection as to be able not only to write and converse freely in it, but even to preach to the young Chinese ecclesiastics. During the same period he acquired the Armenian, the California, some of the North American Indian languages, and even the "impossible" Basque. And it was in Rome, and especially in the Propaganda, that he displayed in its greatest perfection his singular power of instantaneously passing in conversation from one language to another, without the slightest mixture or confusion, whether of words or of pronunciation.

Mezzofanti, as cardinal, was a member of many ecclesiastical assemblies in the last part of his lifetime, and it is difficult to determine with accuracy the number of languages in which he held conversation. It is certain that the number of these was very large, and that he was among the greatest living linguists of his time. During his lifetime, as well as after his death, he wrote many papers in various languages, and translated works from one language to another, and his knowledge of languages was so extensive that it is difficult to institute any direct inquiry; but, judging from analogy, and relying on the well-known modesty and truthfulness of Mezzofanti, we need not hesitate to accept his own statement as reported by P. Crescenti, the more so, as among his papers now in the possession of his family is a list, drawn up from memoranda contained therein, of no less than a hundred and twenty languages with which he possessed some acquaintance, unaccompanied however by any attempt on his part to give the number which he spoke, or the degree of his knowledge of each.

In general learning Mezzofanti's attainments were highly respectable. He was a well-informed theologian and canonist, and an impressive though not eloquent preacher. M. Libri, the historian of mathematical science in Italy, found him well acquainted with algebra, and reports an interesting conversation which he had with him on the Bija Gannita (the algebra of the Hindus), as well as on the general subject of Indian history and antiquities. Other travellers among the orientalists of the time have described him as entering freely into the history as well as the literature of their several countries. But as an author he is almost unknown. He occasionally read papers at various literary and scientific societies in Bologna and Rome; but this was the only knowledge which he communicated to his friend and brother professor, Father Emmanuel Apeote, which was printed at Bologna in 1620; and he leaves no monument for posterity beyond the tradition that he was incomparably the greatest linguist the world has ever seen.

MICA, a Mineral belonging to the extensive series of Silicates of Alumina. It occurs in oblique rhombic prisms of about 190° and 60°. The crystals usually with the acute edge replaced. The cleavage is very decided, yielding easily thin, flexible laminae. It is found usually in thinly foliated masses, plates, or radiated groups of aggregated scales or small folia. The colour is from white, through green, yellowish, and brownish shades to black. The lustre is more or less pearly. Transparant or transparent. The hardness 2 to 2½. Specific gravity 2.8 to 3.0.

The composition of micas is as follows:

- Silica
- Alumina: 46.3
- Potash: 36.8
- Phosphates of iron: 9.2
- Fluoric Acid: 8.5
- Water: 0.7

A variety in which the scales are arranged in a planar form is called Plumeose Mica; another in which the plates have a transverse cleavage, has been termed Prismatic Mica. Micas resemble externally talc, and some forms of gypsum. From talc it differs in affording thinner laminae, and being elastic. It also has not the greasy feel of talc. The same characters except the last distinguish it from gypsum, besides which it does not differ.

Mica is one of the constituents of granite, gneiss, and mica-slate, and gives to the latter its laminated structure. It also occurs in granular felsitones. It is found abundantly in the United States, in Russia, in Great Britain, and other parts of the world. It is often found in large isolated masses, but filling up the veins and fissures of rocks, into the composition of which it enters. It occurs in the oldest rocks, as well as in these which are new and possess a crystalline character.

In Russia it is used extensively as a substitute for glass, and hence it is called Nacorry Glass. The very thin laminae are employed for examining objects under the microscope. Haüy states that these laminae are sometimes not more than the 1-300,000th part of an inch in thickness. Lepidolite, or Lithia Mica, occurs in crystals or laminae of a purplish colour, and often in masses consisting of aggregating scales. It occurs in the Ural. According to Reauleau, as quoted by Dana, it consists of the following analysis:

- Silica: 47.7
- Alumina: 20.3
- Lithia: 6.3
- Protoside of Manganese: 4.7
- Potash: 11.0
- Lithia: 2.8
- Soda: 2.3
- Fluorine: 10.2
- Chlorine: 1.3
- Other: 106.3

Fusculite is a green Mica from the Zilleralp, containing nearly 4 per cent. of oxide of chromism.

Lepidolite Mica is the most common. The two species have been made out of the old species so called. The common Mica has an oblique prism for its primary, but many micas when

Note: The text continues with the analysis of various minerals and their properties, likely discussing their uses and characteristics in detail.
396 is very Dziady, prisoner Polish there, still Dziady, another, again merit, every 'Graiyna' Byron, It addressed university when from of ania so certainly ever leaves. These perfect MICKIEWICZ, Ottrelite deeply afterwards, to English first after finishing by ancient. Mickiewicz made that of Wilna. They found in Pennsylvania, United States.

Nacrie resembles tale, but contains no magnesia. It is whitish and soft, and has a greasy feel. Lepidolitane is a black iron mica, occurring in 6-sided scales or tables aggregated together. Celarite is a mica occurring in black scales. Oderit is probably a black mica. It can be split into thin leaves. It is opaque, black, and has very little lustre.

It occurs in Sweden. MICKIEWICZ, ADAM, the greatest poet that Poland has ever produced, was born in the year 1795 at Nowogrodek, a small town in Lithuania, one of the few in the environs of which the ancient Lithuanian language is still spoken. It is certainly remarkable that a man, the chief effort of whose life was to prevent the language, the nationality, and the religion of his country from being lost, should be the native of a country which had lost its language, its nationality, and its religion by its union with Poland. His father, by birth a noble, was by profession an advocate, and an unsuccessful one, his brother afterwards became a legal writer of some reputation. Mickiewicz himself had so little respect for the nobility of his family, that in his poem of 'Pan Tadeusz,' in which the scene is laid in Lithuania in the year 1018, he introduces his family name as that of a commoner and illiterate brazier in a pothouse. It is singular that Pushkin, who acquired the name of the Russian Byron as Mickiewicz did that of the Polish Byron, takes occasion in his play of 'Boris Godunov,' to introduce one of his own ancestors in an odious and contemptible light. The feeling of the two poets in the respect was very different from that of their English prototype.

Mickiewicz after receiving his preliminary education at Nowogrodek and the grammar-school of Minsk, was sent when nineteen years of age to the University of St. Petersburg, his uncle, an ex-Jeniat, was one of the professors. The university under the anepiscopes of Sniadecki the mathematician, and the patronage of Prince Czartoryski, then Minister of Public Instruction, was at that time in the full tide of prosperity, and learning and knowledge of the population of Russian Poland, and celebrated for the success with which the exact and natural sciences were taught. Almost the first person whom Mickiewicz saw at Wilna was Thomas Zan, a celebrated Polish patriot, who was occupied with getting up secret societies among the students, of which Mickiewicz at once became a member. The professor of history, Lelewel, was another determined opponent of the Russian government, and to him Mickiewicz addressed his publication under the title of 'Blindness,' and fell deeply in love with the sister of a fellow student, Maria Wereszczakowa, by whom his addresses were finally rejected for those of a richer author. When he left the university, where he had been noted for his devotion to chemistry and afterwards to poetry, he was appointed professor of classical literature in a college at Kowno, and it was while residing there in 1822 that two small volumes of poems from his pen were published at Wilna. Like those of Burns and Byron, they were made at various degrees of merit, some of them spirited, others pleasing, and others again poor and commonplace. But two poems of the set, 'Grajyna,' and 'Dziedy,' are of a very high class. In 'Grajyna,' in which the poet takes for his scene the old castle of Nowogrodek, the ruins of which are still remaining near his native town, he tells in a tersely classical and sculptural style, which reminds the reader of the happiest effusions of Tennyson, the story of a Lithuanian heroine, who, to save her country from the hands of oppressors, marries her own brother, and meets death on the field of battle. It became the favourite poem of a real Lithuanian heroine, Emilia Plate, who eight years afterwards fought in the Polish ranks in the inscription of the battle of Kraszew near Wilna. The 'Dziedy,' or 'Ancestors,' is a poem of a new kind, an autobiographical drama, in which the poet appears as one of his own characters. In it the poet relates, with this slight veil, the story of his love for Maria, the 'Mary Chaword' of his poem of 'Dziady,' who afterwards married the Prince in Byron's style. Afterwards rendered into Polish, it would be difficult to find a love-tale more tenderly and delicately told. The name of Mickiewicz became at once popular among his countrymen. A valley near Kowno, which he was fond of visiting, and where he wrote some of his verses, received the name, which it still retains, of 'Mickiewicz's Valley.' The enthusiasm of the Poles was heightened by the next intelligence that spread far and wide concerning him, that he was an exile. The hands of the Russian government and suspicion of being concerned in the secret societies which had been found to exist in the University of Wilna. The dedication of the 'Poems,' containing 'Dziedy,' had been to Thomas Zan and a few friends, and probably the poet little anticipated that it should attract so much attention which was the part of the 'Dziedy,' published after long years of interval—"To the sacred memory of John Sobolewski, of Cyprian Daskiewicz, of Felix Kolakowski, my fellow-students, my fellow-prisoners, my fellow-exiles, persecuted for the honour of our religion and our country, whose valiant and noble souls are laid by the side of the small valleys in which their hearts died at Archangel, at Moscow, at St. Petersburg, in the march of their country's cause." Imprisoned for upwards of a year in the Bastilian convent at Wilna, while the examination to save the honour of his homeland and the cause of Russian education were directed, and those which were afterwards delineated with all the force of his genius, Mickiewicz, found guilty of being a member of two secret societies, was condemned, in 1824, to perpetual banishment in the interior of Russia. At the age of twenty-six, Mickiewicz left Poland for exile, and he never saw it again.

At St. Petersburg, where he was at first permitted to reside, Mickiewicz found himself, in the latter years of the Emperor Alexander, in the midst of native conspirators against the government, and in the service of the Russian government, active in the abortive insurrection at the accession of the Emperor Nicholas, were ardent for the Polish cause. In a poem "to his Russian friends," written in after years, Mickiewicz men- tioned that he was sent to Wilna, with a commission to put a car, and alludes apparently to Pushkin, to whom they intro- duced him, as having deserted the cause of liberty. The Russian Byron and the Polish Byron met at St. Petersburg in the year of the death of the English Byron. Po- litical disjunction was not looked upon with favour by those eyes by the Russian government, which ordered Mickiewicz to Odessa; there, however, he soon obtained permission for a tour in the Crimea, which gave rise to a series of 'Crimean Sonnets,' the first sonnets in the Polish language. This subject now gives them an additional interest. One of them is "On the View of the Mountains from Kozlov, or Barta- toria; another, 'On the ruined Castle of Balaklava." These poems have been very popular; and one of them, 'On the ruined Castle of Balaklava,' has been translated into Russian, and afterwards translated into Persian; but we believe that from no other poems of Mickiewicz could so many instances of false brilliancy and other common-place be selected. They obtained for him an invitation from the governor, Prince Golitsin, and afterwards to live among them in detail; it incites the most burning hatred on the part of a cruel nation to its foreign oppressors. Its meaning, which was at once apprehended by every Pole, seems to have escaped
every Russian. Two Russian translations were published, and it is even said that the Emperor Nicholas sent a message to the first one of the Polish government, that the Russian service was also, it is said, preferred to him; but the only favour he asked was to be allowed to visit Italy for the benefit of his health, and he obtained it by the intercession of the Russian poet Zhirzhevsky. He left Russia, as he had promised in 1837, but he returned in 1838 to his life of complete solitude.

After passing through Germany, where he spent some days with Goethe, he resided at Rome, where he became intimate with James Fenimore Cooper. It was at Rome that the news of the Polish insurrection of 1830 reached him, an insurrection which he had for some time been awaiting; and it was there that he composed his great and immortal ode 'Ode to Youth.' The rising was crushed by the time Mickiewicz had reached Posen on his way to join it. He returned to Dresden, and there composed the second part of the 'Dzidzery,' which was first published in 1832 at Paris.

As in the former part of this poem Mickiewicz had told in a dramatic form the tale of his early love, in this he related in a succession of scenes the story of his imprisonment in Wilna before the sentence of banishment. As a lover, he represented himself as having been driven by disappointment to insanity; as a man, he actually delineated himself as possessed by the devil, and the devil as exorcised out of his body by a priest, after the atonement of a proud and presumptuous savage, whom the poet represents as having called down the chastisement. This strange and repulsive scene is accompanied by others of a less eccentric character, in which the poet's friends and followers are represented as rescuing him from the horrors of the Russian sway in Poland are depicted with surprising power and pathos. On the whole, this wild production is one of the most remarkable for poetical power that the literature of the quarter of a century since 1830 has produced.

The last great poet of Mickiewicz's, 'Pan Tadeusz,' or 'Sir Thaddeus,' was published in Paris in 1834. It differs as entirely in style and sentiment from the 'Dzidzery' as 'Waverley' from 'Manfred.' It is a minute delineation of the last of the great epoches of Poland, of the poet's boyhood, in which the somewhat insignificant story of a commonplace here is relieved against the dark background of the approach of Napoleon's invading army on its march to Russia, and the intense excitement it produces amongst the Lithuanians, from the peasant and the publican to the priest and the noble. By some it is regarded as totally unworthy of the powers of Mickiewicz—by many as the finest production of his genius; and there can be no doubt that he is by far the most pleasing and the least objectionable.

Up to this period the career of Mickiewicz had been one to which his Polish admirers had looked with constantly increasing admiration, and he occupied a position in the literature of the world similar to that of the French poet's boyhood, in which the somewhat insignificant story of a commonplace here is relieved against the dark background of the approach of Napoleon's invading army on its march to Russia, and the intense excitement it produces amongst the Lithuanians, from the peasant and the publican to the priest and the noble. By some it is regarded as totally unworthy of the powers of Mickiewicz—by many as the finest production of his genius; and there can be no doubt that he is by far the most pleasing and the least objectionable.

Since his and any Mooches minute whilst he person must, remarkable passage he delineates his young hero in the palace of his foe as descending to the meanest spite—

I secretly sharpened my knife, and with what a rapture of vengeance I cut the carpets of Wijnroch, and raised his glittering mirrors.

It is said that at the time of the appearance of this passage in the works of Mickiewicz, and the publication of the first volume of the Dunia, or the daily national paper, Count Constantine at Warsaw carried out the idea. The gross anachronism of the carpets and the mirrors in a story of the 14th century is only one of many which abound in the works of Mickiewicz, and it is not to rely on such evidence. Yet, the question is, whether his views and theories were concerned. He tells us, for instance, in one of his Napoleonic legends that the genius of Byron was undoubtedly kindled by a ray from that of Napoleon, and that Byron would have been an almost perfect copy of the conqueror. So decrepid and almost dead as that of England, which had as it were come to a close with Thomson and his followers. This general inaccuracy and untrustworthiness must, in fairness to the Russians, be remembered by the readers of the thrilling delineations of their cruelty which abound in the 'Drizady.' Whatever may be the judgment pronounced on Mickiewicz as a writer, a politician, and an historian, nothing can ever erase from Polish literature the mark of his genius as a poet.

MICROSCOPES, USES OF THE. There are few instruments that have rendered such important aid in scientific search as the Microscope. The chief advances that have been made in the natural history sciences, embracing physics, chemistry, botany, zoology, and other sciences, in the 19th century, have been effected by its agency. The structure of this instrument has been described in the article Microscope. It has been gradually rendered more perfect as the science of optics advanced; and its nature and arrangement can only be understood by the study of the principles of this science. We propose here referring to its use as an instrument of natural history and physiological research, and of those general arrangements and applications by which its utility can at all be fully secured. It is at once sufficient that a man possesses eyes in order to observe accurately, nor is it the possession of a costly microscope that will enable a person to confirm the observations of others or make discoveries of his own. The use of the microscope by uninstructed and uncurious observers has given rise to many absurd errors. "The fruit of the mulberry has been mistaken for Rhusococcus; calcareous corpuscles have been regarded by several observers as ova, and the appearance arising from the presence of concentric laminae has been interpreted to be the cells of an object fully developed. In my own experience, I have seen the animalcules in the mouth of a lizard; minute corpuscles in blood; minute spicules in chalk and coral; minute hairs projecting on the surface of a membrane have been declared to be spicules within subjacent cells; and quite recently one writer states, that certain minute bodies which he has examined are either blood-corpuscles or the spores of fungi, but which is doubtful! while another recognizes, how, by accident, he discovered that corpuscles, which he had regarded at first as consisting of fat, were afterwards found accidentally to consist of calcareous salts!"

Again, we read in zoological works of the yolk-cells, and the coloured oil-globules of the yolk; and a beautiful function of assimilation has been attributed to them; but they exist only in the imagination of the authors, who have regarded the one as cells, simply because they are round, and the other as oil, because they are yellow. But the yolk-cells have also been regarded as mucus cells, and again as blood-corpuscles; minute fossils in chalk have been strung together with portions of vegetable tissue, and (perhaps) the spores of fungi; minute bodies resembling small hair-like spicules have been regarded as spicules; and minute bodies resembling the neucleolus have been described as spicules within subjacent cells; and quite recently one writer states, that certain minute bodies which he has examined are either blood-corpuscles or the spores of fungi, but which is doubtful! while another recognizes, how, by accident, he discovered that corpuscles, which he had regarded at first as consisting of fat, were afterwards found accidentally to consist of calcareous salts!"

In microscopic observation two things must be remembered: 1st, That the microscope is especially with high magnifying surfaces, not bodies. It frequently happens that in looking upon surfaces, we get a glance into the depths, of transparent objects by changing the adjustment, without altering the position of the object; it often happens however that, in looking upon opaque objects, we are unable to make them out to be bodies until we have changed their position, and ascertained their dimensions in three different directions; this, in many cases, from the nature of the object itself, in a mass of dead matter, such as a pellet of mica, or under the microscope in their natural condition; that we consequently must take into consideration the changes which we ourselves partly produce, either by the medium in which the object is placed, or by the use of the microscope itself, and that every thing we see through the microscope secures the observer from deceptions which arise, not from any fault in the instrument, but from a want of acquaintance with the microscope, and from a forgetfulness of the width of difference between common vision and vision through a microscope. Deceptions also arise from a want to distinguish between the natural appearance of the object under observation, and that which it assumes under the microscope.

The proper use of the microscope is always the principal thing to be considered. Hedwig, with the microscope of his time, accomplished the advancement of science to a greater extent than any observers with incomparably better instruments have done.

In order to use the microscope properly, the observer must be skilful in handling the instrument and the objects, and above all things, his mode of proceeding must be conducted with accuracy and judgment, and he must be able to give a sufficient reason for every thing that he does. His progress in research will be slow, but sure; he must endeavour to obtain objects from every possible source, and must examine them carefully and scrupulously, as well as possible, and so, progressing step by step, he will attain the desired end. Work without method will seldom lead to any result; the finest sections of wood made in a microscope, will not be of much use to the observer if they are not conducted in a proper manner, and well-prepared specimens of the successive conditions of the wood, furnish irrefragable proofs, the one of the construction, and the other of the development in the growth of the wood under observation. (Schacht on the Microscope.)

Before speaking of the methods of examining and preserving bodies for microscopic observation, it will be better to draw attention to the natural objects, to the examination of which the microscope is especially adapted. In the inorganic and organic worlds the microscope is made subservient to observation. To speak first of inorganic substances and materials not under the influence of vital action.—It has been found of great use in determining the forms of minute crystals. In this way it aids the analytical chemist. In the examination of the saline contents of water, if a small quantity of the water is allowed to evaporate upon an ordinary glass slide, its contents may be judged of by the crystals which the crystals are obtained from these bodies this plan of examination has been recently applied with the most interesting results. A series of the most beautiful illustrations of the microscopic characters exhibited by crystals obtained by the evaporation of sea water has been given by Prof. Funke's 'Atlas of Physiological Chemistry,' and also in the 'Micrographic Dictionary,' by Dr. Griffiths and Mr. Henfrey.
Not only are the natural crystalline constituents dissolved up in liquids thus obtained, but new combinations obtained by the addition of re-agents. This mode of inquiry is equally applied to the minute parts of the human body, and is rapidly becoming one of the most important means of diagnosis in the hands of the physician.

Although dealing with the disposition of large masses of matter, of which the earth’s surface is composed, important knowledge has been gained as to the existence of the various portions of them with the aid of the microscope. It is by the aid of this instrument alone that the question of the manner in which an extensive series of rocks has been deposited, and also the mineralogical and homogeneous surface, when sections are made of them and placed under the microscope, are found to consist of the remains of the minuteest forms of organic beings. [Diatomaesser, S. 2; Irresso.] When, on the other hand, rocks which, like the Oolite, present the appearance of being composed of various forms of organic beings, on close examination with the microscope are found to present appearances due to purely physical causes. Each of the little egg-like beads seen in these rocks is found to contain a particle of sand surrounded by carbonato of lime. [Oolite, S. 2.] It frequently happens that the fossilised parts of the higher animals which are left in the solid rock are too small or shapeless to indicate the characters of the forms of which they were composed, but by the microscope this question can be determined in multitudes of instances. It has been found by the recent researches of Dr. Carpenter and others, that the microscopic characters afforded by the structure of shells are frequently so distinct as to enable even the most untrained observers to distinguish them. [Mollusca.] This is a subject of the highest interest to the geologist; for of all the remains of animal life those of the Mollusca, from the hard nature of their shells, are those which are furnished to him in greatest abundance for distinguishing the character of different strata, and determining their relative age. Amongst the vertebrate animals, next to the teeth, the bones are the parts which are most frequently left in rocks. When the form of the bone is no guide, its microscopic structure, whether it is compact or spongy, with which it belongs. The forms presented by the lacune, or bone-cells, which are only visible by the aid of the microscope, are found to differ so much in fish, reptiles, birds, and mammals, as to afford the means of distinguishing each class. The teeth are only modified bone, and although they present most frequently a very definite external form, and are usually better preserved than any other part of an animal body, they afford still more definite characters by the modifications of the space that is occupied by the blood-vessels, and the internal structure of the tooth presents a better character than any other part of its structure in the gigantic extinct frog, the Lozzerinodon.

Among the earlier fishes which inhabited the seas of the earth, and which bore no resemblance to those which have a cartilagenous skeleto; but with this perishable skeleton they were endowed with hard scales, which have resisted all decomposing agencies, and these scales, frequently scattered, are the only record of their existence. From microscopic examination of the structure of these scales, Professor Williamson has shown that the species of those fishes can be detected.

Numerous are the forms of Zoophytes, Polypora, and Echinodermata that have left remains in the strata of the earth which the naked eye can by no means distinguish, but whose differences are immediately revealed when sections of their fossilised remains are placed under the microscope. Examples that will be found in the second volume of Professor Quatrefyett’s ‘Dictionary.’

We pass from this glance at the use of the microscope to the chemist and geologist, to point out its value in researches connected with living organised beings. We begin with plants. It is in the vegetable structure that the ultimate cells, of which all organised beings are composed, are most easily discerned. The earliest microscopic observers were aware of this. It was left however for Schleiden to perceive the full significance of this fact in 1838, when he drew attention to the fact that a single cell is the elementary unit of the cell. [Cida, S. 2.] He was followed by Schwann, who pointed out that the cell was of equal importance in the animal as the vegetable kingdom. The ultimate cell of the plant or animal is only visible to the aid of the microscope; hence whatever importance is attached to the discovery of cells and the formation of tissues by their agency is due to the use of the science of microscopy.

The incessant labours of microscopic observers during the last century have enabled us to determine the nature of the vegetable kingdom, to distinguish minute animals and plants, inhabiting more especially water, and which are perfectly invisible to the naked eye. The earliest observations on these minute beings were made by Leewenhoek; but for these we are indebted to both Quekett’s and Lant’s. [Oolite, S. 2; Irresso.] Since the publication of the latter, observers have been enabled to distinguish a large number of genera and species, and consequently to form the idea that the microcosm is a source of increasing interest to microscopic observers. Representing the entire animal or plant in its simplest form, the observations of their growth, structure, and functions have thrown light on some of the most complicated problems of animal and vegetable physiology. Small as they are, they make up for want of size by the prodigious numbers in which they occur, and the important functions they seem to perform in the universe. The unveiling of this world of life is therefore deeply important.

It is not however alone in revealing the minute structure of plants and animals, as the existence of organic beings of minute size, that the naturalist and physiologist are indebted to the microscope. By its aid they have been enabled to investigate the fundamental laws of organicography, and to verify the facts that plants and animals are built up of cells it was a natural inference that these cells performed an important part in the functions of these tissues. It was soon found that the animal and plant increased in size by the multiplication of these cells; that the tissues were renewed by their agency; that the function of secretion was performed by them; in short, that it was by the aggregate of their functions that plants and animals lived. Hence the cell theory, or cell organisation of the universe, the definition of which living beings what the law of gravitation was to the phenomena of the physical universe. Till the application of the microscope the mysterious function by which new beings in plants and animals were produced was only imperfectly apprehended; but since its extended employment the laws which regulate this process have become perfectly obvious, and but little remains to complete our knowledge of the subject. [Reproduction in Plants and Animals, S. 2.]

Having thus traced in outline the uses of the microscope, we now proceed to give some general directions for examining them. In giving these directions we shall follow Dr. Schacht, whose work on the microscope has been translated into English by Mr. Currey.

One of the principal advantages for microscopic investigation, besides a good instrument, is a proper supply of light. When the position and nature of the apartment can be selected at pleasure, a room should be chosen having windows facing the west or the north, or, what is better, a room with windows towards both those quarters of the heavens. The windows must be as high as possible, since the light received from the horizon is the most favourable; light reflected from a white wall, or the light of white clouds, is often very advantageous. The light of sending clouds is imparted by the rapid change in the intensity of light, besides rendering necessary a continual change of position of the mirror. No ordinary observation is possible in direct sunlight; the eye is dazzled, and balding for the eye to be quite hot; and, in the second place, it cannot be discerned which give rise to the grossest deceptions. In working with the microscope in the forenoon and in the middle of the day, a room lying to the east or to the south, must therefore be avoided: means of white, blue, or green, the inconvenience may, to a certain extent, be avoided.

Many objects are seen very beautifully by lamp-light, but this light is far more glaring than daylight. When the light is made to pass through blue glass before reaching the mirror, this is to be preferred. By this means the eye is protected from direct light, and the light is diffused and directed by the eye to the eye. A piece of white ground-glass, fastened in a wooden frame, and placed before the lamp, will have the same effect. By regulating the light of the lamp in this manner, objects ready prepared may be shown very well at night, but it is hardly possible to make fine preparations.
with such an illumination; for exact observation, therefore, the
daytime only must be selected. In order to intercept the light,
the microscope is placed at least three feet from the window, the
latter of which is carefully shut. If the light is, in fact, sought after;
when the field of view appears clearest and brightest, the object
which is to be observed is placed under the microscope.

When it is desired to examine opaque objects with inci-
dent light, the microscope may often be advantageously
brought nearer to the window. Since for this kind
of illumination a much larger quantity of light is necessary,
direct sunlight is sometimes desirable; in the absence of this,
the condensing lens is used, by means of which the greatest
possible amount of light is concentrated on the object.
In this kind of illumination, the access of light from below,
which would interfere with the observation, is prevented by
closing the diaphragm. For objects which are altogether
opaque, a background which is white, but not glittering, is
often advantageous.

The table at which microscopical observations are under-
taken must be sufficiently large, and very firm; it must be
so arranged that all the apparatus which is ever wanted shall
be within reach of the hand. For so small a space as this,
in microscopical investigation times pass only too quickly;
moreover, in a very confined space, it is impossible to make
effectual preparations with the simple microscope. Every
object intended for investigation should be examined first
with the low-magnifying power, since by that means a far larger portion of the object is seen, and thus a
better impression with regard to the whole is obtained.
Should the light be too strong, the plane mirror may be used instead of the concave one. When that has been done
as much information as he can with the low-magnifying
power, for instance, one of 50 diameters, or, in some cases, even
a less magnifying power, the object-glass is changed for a more
powerful one. When the most powerful object-glass has been
examined, and a still stronger magnifying power is desired, then
a stronger eye-glass is taken. As a general rule, the eye-glass of
lowest power should be used, and, if necessary, the magnifying power should be increased by pass-
ing through the object-glasses of lower power to those of higher
power; but, nevertheless, for seeing with convenience, and
especially for drawing, the use of a powerful eye-glass is
often not without advantage. As long as the magnifying
power can be increased by means of an object-glass, recourse
should never be had to a stouter eye-glass, for the sharpness of outline of the image are necessarily dimin-
ished by the use of a powerful eye-glass, which is not the
case in using a more powerful object-glass.

A good plan is to be followed when the left
hand is made with the left
hand, the eye which looks into the microscope. When
an object is thin enough to be transmitted light, it is first
illuminated with light transmitted directly, and is ex-
amined with different, and gradually increasing, magnifying
powers; should any details of the image remain undefined,
often transmitted light is used, which is instilled into all
the different corners of the object. In some microscopes
this is attained by turning the stage round its axis; where
this arrangement is wanting, the position of the object
must be changed by moving it with the hand. Lines always stand out most clearly when oblique light falls upon them at a
right angle; where, therefore, a line is suspected to exist, or
is only dimly seen, particular attention must be paid to this
circumstance. The object-glass itself is arranged so that the
same rule generally holds good, and particular care must be
taken, by turning either the stage or the object itself, to con-
centrate the light in all possible directions upon the object.
Object-glasses of very high power cannot be used with
incidental light, since then the incident light prevents the
light from falling on the object; in this case recourse must be had to less powerful object-glasses, and more
powerful eye-glasses. As a general rule, low-magnifying
power is used with an incident light.

Objects are frequently examined by polarised light.
In order to effect this an instrument called a polariscope is
employed. That most frequently used is the arrangement
invented by Mr. Nicol. It consists of two prisms of
Iceeland spar, which is fixed on the stage of the
microscope, but another is attached to the eye-piece. Tourmaline is also used for the same purpose.

Large crystals of lodine of quinine
have also been shown by Dr. Harapati to be applicable in
polarising light for the microscope. (Quarterly Journal of
Science, vol. viii. pp. 274, 275.) Microscopical objects often exhibit the structure in a more per-
fect manner. Various objects, especially crystals of a spherical
or oval form, exhibit a beautiful variety of colour in this
way. For some objects it may be made the means of testing the nature of an object.

In most instances, objects are examined under water: it is
but seldom, as, for instance, in examining pollen or spores,
that it is necessary to observe them in different media, and
also so to arrange that a case of different media is ready.

Lines should never be seen under water, but always in
the inverted position; this is more easily accomplished.

In the microscope, for instance, the embryo of grass, to observe
them first without water, and afterwards under water; by this the exact position of the corneal or lens is
obtained. As for the longer hair brush, the object is generally sufficiently and fully immersed. When low-magnifying powers are used, it is not
necessary that the objects should be placed under a glass
cover, in fact, in many cases where it is wished to have the
power of turning the object round, or when it is thought that
the object may be improved by any additional cutting or pre-
paration, it is very advantageous not to cover it; when
object-glasses of very high power are used, the focal distance
is so short that one can, in this case, lay the object, or dip it in
the fluid upon the object plate, it is necessary to make use of glass covers. When these are
used, the fluid in which the object lies frequently becomes
exposed by evaporation, especially in a microscope in which a case of fine dust is added at the edge of the glass cover by
means of a glass rod, or a clean camel's-hair brush, which
may be used when it is wished to add a solution of iodine,
or of chloride of zinc and iodine, to objects which are already
immersed in water.

When any chemical re-agents are used, whether iodine,
caustic potash, or an acid, the object should always be
covered with a thin plate of glass; in using volatile acids,
such as nitric acid and hydrochloric acid, too much care
must be exercised in the prevention of any contact between the
object and the fluid. In many cases, a very injurious effect upon flint glass, which is used by some
opticians for the under side of the object-glass.

When the microscope is in daily use, it is a good plan
to keep it under a high bell-glass, or an ornamental shade.

The greatest cleanliness and accuracy are indispensable
for microscopical investigations: it must be laid down as a rule
that the microscope must never be allowed to come in con-
tact with outside bodies. Excessive things of this kind will
not easily deceive a practised observer; a beginner however
may be easily misled by them. Water which has been left
standing for a few hours, and which contains a little of the
air, contains in it and in- water, dissolved air, in which
contains the inferior sorts of animals and plants, and when
under different objects are examined one after another, fresh water
should be taken for each new object, in order that no
particles of the objects which have been previously examined
may be mixed with the water upon the slide. This may be traced to a neglect of small precautions of this sort.

In order to be able to recognise extraneous objects as much,
it is advisable to gain an acquaintance with those things
which, notwithstanding all precautions, cannot always be
avoided. To this class of things belong: 1st, Air-bubbles,
which, with transmitted light, generally appear in the form
of circles of larger or smaller diameter, with a dark, black-
looking rim: with incident light, on the contrary, their
rim appears green; 2d, Coloured objects, which may be
covered and in contact with it, the large air-bubbles frequently
assume a very irregular shape; the above-mentioned optical
fact is generally however by far the best proof of the
presence of air, and by it the presence of air may be detected
both in and between the cells of plants. Coloured fibres, of
colour, or fine, wool, or silk-threads, left behind upon the object-glasses, from the clothes with which
they have been cleaned, and also the hairs which have
been caught in the hair of the brush, and the dust of irregular shape, which are frequently coloured,
and are probably produced by the decay of organised bodies. If
it is wished to examine plants, or parts of plants, which grow
in or upon the earth, or in water, great attention must
be paid to this subject. If a plant is brought in contact with
the it is not met with; pains must be taken by careful observation to
become acquainted with the lower forms of animals and

MIC 400

MIC
plants: it is necessary, for instance, to be able to distinguish the common forms of Infusoria, both those that are known to be edible and those that are not, because the yeast plant, the different forms of mould, the Oscillatoria, and such like things, in order to be able to separate them from the particular object under consideration.

The epithelial cells of the mucous membrane of the mouth are often seen as such when the brush is drawn through the mouth previously to bringing an object upon the object-plate. It is advisable never to pass the brush through the mouth. When in cutting the cell, it is necessary to be those, and forefinger, or upon the forefinger alone, it often happens that small fragments of the skin of the finger are cut off at the same time. The observer must learn to distinguish these fragments, as well as the small pieces of cork which he will make, from the other fragments of substance. When sections in different directions, must be carefully examined and compared with one another before the observer can be satisfied that he has made out the construction of the body under observation. That which in objects of large size is attained by the help of the knife, is effected, in the case of very small opaque objects, by examining them on different sides. In examining small bodies which are very transparent, as, for instance, the ovules of Orchideae, or grains of pollen or other small objects, the most advantageously placed the watch-glass the question of time to time, by which means the upper side of the object is first brought into the focus, then the middle (which may be called an optical section, transverse or longitudinal, as the case may be), and, lastly, the under-side. The more the object is deformed, the more sensitive is the instrument to any small alterations of the focus, on which account the observer should always keep his hand upon the fine-adjusted screw whilst the adjustment is employed upon observations requiring much accuracy. The sensitiveness above mentioned grows smaller as the objects, in proportion to the magnifying power, and also with the angle of the aperture of the glass.

The accurate adjustment of an object is judged of by the sharpness of its outline, and the manner in which it is placed. The adjustment is more accurate in proportion to the delicacy and sharpness of the lines seen upon small objects, and also in proportion to the fineness and clearness of the outline, which should be both, but well-defined. The scales of the Hippocampa Jancra, a common brown butterfly, are well adapted for enabling a person to judge of the accuracy of an adjustment; the smallest change of focus causes transverse striae to disappear. In examining small round bodies, such as pollen-grains, the position of the object, as the stage is moved, is best judged by pushing the glass-cover so as to cause the bodies to roll about; by this means different sides of the objects are seen, and from the different images presented to the eye their true form is made out.

Small objects should never be compressed between two glass sides, that being too rough a method of proceeding. If however it is supposed that anything is to be gained by compression, then it is advisable to use the compressarium, which is an instrument consisting of a mechanical arrangement by which the thin glass covering an object may be compressed at will. When the compressarium is cautiously used, the observer, by carefully watching what takes place, can gain a knowledge of the changes produced by pressure during the time the compressarium is permitted to work. In certain cases, where, for instance, the question is whether a particular object is a delicate cell or a drop of some fluid, the compressarium may be of service; since, if a cellular membrane be present, it will burst and discharge its contents as the pressure is increased, whereas the drop, whether it be oil, liquid resin, or any other chemical substance upon the slide, will only change its form.

In examining any object, whether animal or vegetable, it is not sufficient to observe the nature, form, and arrangement of the cells; it is necessary also to pay attention to their contents, which, in the case of plants, are different according to the functions assigned to them by nature. It is necessary, therefore, to distinguish—1st, Whether a cell is empty, that is to say, whether it contains nothing, or is filled with perfect vessels and wood-cells; 2ndly, Whether its contents are fluid with a solid substance contained in the fluid. Another question which arises is as to the nature of these contents. They may be of a coagulable fluid, or of a fluid of different consistencies, apparently not intermingling with one another; the manner in which they
bolting-tube; to this is added, in a little while, an equal volume of chlorate of potash, and as much nitric acid as is at least sufficient to cover the wood and the potash; the tube is then warmed over a spirit-lamp; a brisk development of gas quickly appears; the bolting-tube is withdrawn from the flame, the oxidising mixture is permitted to work for a minute and a half or three minutes, and the whole is thrown into a saucer with water: the small pieces which adhere slightly to one another are then collected, placed in the bolting-tube, and boiled repeatedly with alcohol, until the liquid has a transparent appearance. This process is repeated two or more, for the last time, with water. By the help of the simple microscope the cells are now separated from one another with a needle, and selected. The bolting with nitric acid is done on a thin plate of glass, which is carried on in the room where the microscope is kept, because its glass might be injured by the evaporation which is developed. Thin sections of plants, for instance, of woods or leaves, are warmed for half a minute, or a minute, in a watch-glass; the boiling is unnecessary in this case; the section is taken out with a little rod, and thrown into a small watch-glass with water. Nitric acid is one of the best agents for removing animal or vegetable tissues from silicea, as in the case of the Drosophila.

Oil of lemon, or any other essential oil, for examining pollen and spores.

10. A tolerably strong solution of muriate of lime (one part of dry muriate of lime, and three parts of distilled water) for preserving microscopic objects. This is useful for most organic tissues. If it is wished to preserve an object for a few days without mounting it immediately, it is a very good plan to put a drop of this solution upon the object, and to place it under a bell-glass for protection against dust. It preserves the objects for the first few hours; after 24 hours, however, it appears more clearly.

11. Glycerine. This is also well adapted for preserving microscopic objects, and especially for cells which contain starch, which latter substance continues unchanged by it. In granules which exhibit lamination, for instance in the pollen-spores, the lamination is in general continued invisible for the first few hours; after 24 hours, however, it appears more clearly.

12. Copal varnish, or Canada balsam, also for the preparation of microscopic objects; these are only suitable for a few thin sections of wood, or of fossil wood. They both make the object more transparent than the solution of muriate of lime.

13. A tolerably strong solution of carbontartrate of potash, as well as balsam, for digesting fossil woods which have been converted into carboxace of lime. It is also recommended for examining the sweat-dirt in the skin.

14. Acetic acid. This is very useful in examining animal tissues, as it has the power of making the cell-wall clear, whilst the nucleus becomes darker and more distinct. It also distinguishes phosphate or carbonate of lime from oxide of lime, by dissolving the former whilst it has no action on the latter.

15. Very dilute chromic acid. It is used for the purposes of hardening tissues. It is especially useful in examining the structure of the retina.

16. Ammonia will be found useful in the same cases where caustic potash and soda are employed.

17. Nitrate of baryta is used as a test for sulphuric and phosphoric acids. Sulphate of baryta is insoluble in acids and alkalies, while phosphate of baryta is readily soluble in acids, but insoluble in ammonia.

18. A solution of carbonate of soda may be used as a test for chlorides and phosphates. The white chloride of silver is soluble in ammoniac, but insoluble in nitric acid. The yellow phosphate of silver is soluble in excess of ammonia and nitric acid.

19. Oxalate of ammonium is employed as a test for lime, an insoluble oxalate being formed wherever lime is present.

This list of re-agents might be increased, as there is scarcely an operation performed in the laboratory that may not be facilitated by a small stock of the materials admirable in the microscope, and which, if well employed, will greatly increase the number of observations that may be combined with the microscope, and which, if well employed, will greatly increase the number of observations that may be combined with the microscope.
glass, fitted with aground glass cap. It may be fitted with a stand, and will be found useful for submitting objects to heat. The objection to the employment of candles, or lamps, is the black smoke they produce.

2. A small warm bath. This will be found of use for drying the slides, before being mounted in Canada balsam.

3. Watch-glasses are useful for examining substances in fluids with low powers, as by this means a considerable depth of fluid is obtained for observation.

4. The jointing of the slide and cover glass, which is 2 1/2 in. long and 1 in. broad, are useful for mounting and examining all kinds of bodies.

5. Thin glass, called cylinder-glass, of different degrees of thickness, is indispensable for placing over objects, especially those which are soft or fluid when placed upon a slide.

6. Scissors of various sizes will be found convenient for placing thin glass on the slides, as also for placing or removing objects from the slides.

7. Scissors of various sizes will be found convenient for placing thin glass on the slides, as also for placing or removing objects from the slides.

Cement of various kinds are necessary to the microscopic observer who wishes to preserve the objects he examines. They are used for making glass cells to contain objects, on the glass slide, and for fixing the covers over the preparations that have been placed in the cell, and for other purposes. The principal cements need are gold-size, sealing-wax varnish, solution of shell-lac, gum, a French cement composed of lime and India-rubber, Brunswick-black, marine-glaue, and Canada balsam. These cements are sold at the optical stores, and directions for making them are found in some books on chemistry and the microscope.

In order to preserve preparations for a length of time, it is necessary to place them in an air-tight vessel. These vessels are called cells, and are best made of glass. They are also sold where microscopes are procured. With a little practice, however, the microscopist may make his own cells.

Thin cells may be made of various substances. Even paper answers exceedingly well in some cases, and is well adapted for dry preparations. A thin layer of white lead, which has been allowed to dry, has also been employed for the same purpose. White lead, made into a thick liquid with linseed oil and turpentine, has been recommended by some observers. Various other substances have likewise been tried, but where it is required to keep the specimen in some preservative solution, glass is the substance which in all cases forms the best material for making cells.

A blank glass cell is of extreme tenacity that it is only necessary to place them on the slide with a drop of some preservative solution, and then to cover them with a square of thin glass, the edges of which have been anointed with gold size or other appropriate cement. The superfluous fluid is next absorbed with bibulous paper, and the slide allowed to dry for a few minutes. A layer of gold-size or other cement is then applied round the edges of the thin glass in order to fix it to the slide. In this way an excessively thin cell may be formed; but preparations made in this manner should be kept for any length of time without the entrance of air-bubbles. This arises from the outer layers of the gold-size drying more rapidly than the more internal layers. By the contraction thus produced the edges of the cement are drawn off from the glass, to which however it does not adhere with great tenacity in consequence of the surface being highly polished. It is therefore always better to make very thin cells of glass or other material, which can be cemented to the glass all in one piece. Such a cell can be made by the cell by painting the slide with a ring of varnish, marine glue, or Brunswick black, and allowing this to dry thoroughly before the preparation is placed in it. In this manner the thinnest cell may be made in the shortest time.

Perhaps Brunswick black is, for the purpose just mentioned, the best. It is painted upon a glass slide with a fine camel's-hair brush, and allowed to dry perfectly, when, if the cell is not sufficiently thick, another layer may be applied. If the cell be required immediately, it is better to warm the slide slightly before applying the varnish. If too great a degree of heat however be employed, the varnish becomes brittle and the cell unfit for use.

Very thin cells may be made of tin-foil. This may be easily accomplished by cutting with a pair of scissors a piece of thin tin-foil the size of the cell which it is desired to make. A hole is cut in the centre of the tin-foil sufficiently large to hold the preparation which is to be preserved, and this is then fixed over the glass slide with marine glue. When cold the cell may be placed upon a piece of thin tin-foil, or rubbed with a little emery upon a piece of plate glass, and the marine glue should be afterwards removed from the centre with a little solution of potash; or the object may be fixed in the same way as in other cases. Thin cells have also been made of gutta percha, but there is great difficulty in fixing the cell firmly upon the glass slide. This however has been effected by some observers; but in consequence of the difficulty it is a method not generally employed.

Preparations however mounted in cells composed entirely of gutta percha keep very well for a length of time.

Cells composed of very thin glass are perhaps the most convenient for the preservation of objects, especially for many preparations. They may be obtained of different degrees of thickness, and are made usually by perforating the thin cylinder glass which is used for covering the cells, or by grinding sections of a thin glass bottle to the required size. They also may be fixed by being immersed in various fluids. A great number of squares of thin glass are cemented firmly together with marine glue; and when cold a hole of the required size is drilled through them all. They are next separated from each other by heat, and, after being cleaned with potash, may be fixed on the glass slides with marine glue in the usual way, and kept ready for use. It is a good plan to roughen the surface of these cells, which renders the subsequent entry of air less likely, as the glass-size adheres much better to a rough surface than to a polished one. This is readily effected by rubbing the cell, after it has been fixed upon the glass slide, up and down a narrow hone or strip of plate glass on which some moistened emery powder has been placed. In this way also the thickness of the cell may be reduced if required. (Beal.)

Cells of any thickness or depth may be made for larger objects, but those described will be found most convenient. If it is only required to examine the character of a specimen in a dry state, it may simply be laid upon a glass slide and placed in the field of the microscope; if however the substance be of a very delicate structure, or in a minute state of division, it is better to place a piece of thin glass over it in the usual manner in order to protect it.

Dry objects may be placed in a glass slide or in a paper cell, or if of extreme tenacity they may simply be placed on a glass slide and covered with thin glass, which should be fixed to the former by a small piece of gummed paper or by a piece of cellophane, cut to the same size as the glass slide, on which a hole has been cut of sufficient size to permit the entire object being seen. The paper may of course be of any colour, or ornamented according to the taste of the operator.

When objects are to be examined by reflected light they may be placed in little glass or card-board cells, or in pith-boxes, or they may be put up in glass cells. The preparation should be placed upon a dark ground, which may be protected either by a cover-glass or by a fine sheet of paper of the exact size of the cell and placing it within; or the black paper may be fixed on the posterior surface of the slide; or this surface may be covered with black paint or black varnish.

There are various methods by which preparations may be subjected to examination, and preserved as permanent objects in a moist state, and the different value of the various preservative solutions which are in use entirely depends upon the character of the object, and nature of the preparation. Dry preparations form a very good fluid for some objects, whilst for the preservation of most it is necessary to immerse them in water impregnated with some antiseptic agent, which is not volatile at ordinary temperatures. Many again are best preserved in a sealed glass tube, which is difficult to lay down rules which will enable the observer to choose a preservative fluid for any particular specimen. A little experience however will soon enable him to judge which solution is best adapted for the purpose.
We take the following account of several preservative solutions from Dr. Beale's valuable work on 'The Microcosm of London.'

**Spirit and Water.** — Mixtures of spirit and water of various strengths are required for preserving different preparations. In diluting spirit distilled water only should be employed; for if common water be treated with spirit, a precipitation of some of the salts dissolved in it may frequently take place, rendering the mixture turbid and unfit for use. Proof spirit will be strong enough for all general purposes, except for hardening portions of the brain or nervous system, when strengthened, if necessary, with water. Two parts of a rectified spirit, about specific gravity 837, mixed with one part of pure water, makes a mixture of sp. gr. 915-920, which contains about 49 per cent. of real alcohol, and will therefore be about the strength of proof spirit. One part of alcohol, 69 over-proof, over-proof water, forms a mixture of sufficient strength for the preservation of many substances.

Glycerine. — A solution of glycerine adapted for preserving many structures is prepared by mixing equal parts of glycerine with camphor water. The latter prevents the tendency to mildew. It may be used as other preservative solutions.

Glycerine is obtained by boiling oil with latharse. The oleate of lead remains as an insoluble plaster, while the glycerine is dissolved. It may be rendered free from lead by passing the mixture through a column of charcoal; and the clear solution, after filtration, may then be evaporated to the consistence of a syrup.

**Thwaites's Fluid.** — This fluid has been much employed by Mr. Thwaites for preserving specimens of *Drosophila,* but it is also applicable to the preservation of animal substances.

| Water | 16 ounces |
| Spirits of Wine | 1 ounce |
| Creasote sufficient to saturate the spirit. |
| Chalk, as much as may be necessary. |

Mix the creasote and spirit, stir in the chalk with the aid of a pestle and mortar, and let the water be added gradually. Next add an equal quantity of water saturated with camphor. Allow the mixture to stand for a few days, and filter. In attempting to preserve large preparations in this fluid, I found it always became turbid, and therefore tried several modifications of it. The solution next to be described was found to answer very satisfactorily. Water may also be impregnated with creasote by distillation. It should be borne in mind that M. Strauss-Dürckheim has succeeded in preserving preparations in camphor-water only.

**Solution of Naphtha and Creasote.**

| Creasote | 3 drachms |
| Wood Naphtha | 6 ounces |
| Distilled Water | 64 ounces |
| Chalk, as much as may be necessary. |

Mix first the naphtha and creasote, then add as much prepared chalk as may be sufficient to form a smooth thick paste; afterwards add, very gradually, a small quantity of the water, which must be well mixed in a mortar. Add two or three small lumps of camphor, and allow the mixture to stand in a lightly-covered vessel for a fortnight or three weeks, with occasional stirring. Pour off the almost-clear supernatant fluid, and filter it if necessary. Preserve it in well-corked or stoppered bottles.

I have some large preparations which have been preserved in upwards of a pint of this fluid, for more than five years, and the fluid is now perfectly clear and colourless. Some dissection of the nervous system prepaions have kept excellently—the nerves keeping their colour well, and not becoming at all brittle. Two or three morbid specimens are also in an excellent state of preservation; the colour being to a great extent preserved, and the soft character of the texture remaining. I have one preparation mounted in a large guita percha cell, containing nearly a gallon of this fluid.

**Solution of Chronic Acid.** — A solution of chronic acid will be found well adapted for preserving many microscopic specimens. It is particularly useful for hardening portions of the nervous system previous to cutting thin sections. The solution is prepared by dissolving sufficient of the crystallised acid in distilled water, to render the liquid of a pale straw colour.

The crystallised acid may be prepared by decomposing 100 measures of a saturated solution of bichromate of potassa, by the addition of 120 to 150 measures of pure concentrated sulphuric acid. As the mixture becomes cool, crystals of bichromic acid, which should be dried and well pressed on a porous tile, by which means the greater part of the sulphuric acid is removed, and the crystals obtained nearly pure.

**Preservative Gelatine.**

| Gelatine | 1 ounce |
| Honey | 1 ounce |
| Spirits of Wine | 4 ounces |
| Creasote | 6 drops |

Soak the gelatine in water until soft, and to it add the honey, which has been previously raised to the boiling-point in another vessel. Next let the mixture be boiled, and after it has cooled somewhat the creasote dissolved in the spirits should be added. Lastly, filter through thick flannel to clarify it. When required for use, the bottle containing the mixture must be slightly warmed, and a drop placed on the preparation upon the glass slide, which should also be warmed slightly. Next, the glass cover, after having been breathed upon, is to be laid on with the usual precautions, and the edges covered with a coating of the Brunswick black varnish. Care must be taken that the surface of the drop does not become dry before the application of the glass cover; and the inclusion of air-bubbles must be carefully avoided.

**Geadby's Solution.**

| Bay salt | 4 ounces |
| Alnun | 2 ounces |
| Corrosive Sublimate | 4 grains |
| Spirit of Wine | 2 ounces |

Mix and filter. This solution may for most purposes be diluted with an equal bulk of water. For preserving delicate preparations it should be even still more dilute.

**Burnett's Solution.** — This fluid has been patented. Its preservative properties appear to depend upon the chloride of silver. A strong solution of chloride of silver forms a very powerful antiseptic, and also possesses the property of absorbing noxious odours, &c.

**Other saline solutions.** — Many other saline solutions have been employed by different observers. Of these, a saturated aqueous solution of chloride of calcium, free from iron, has been much recommended for preserving specimens of bone, hair, teeth, and other hard structures, as well as many vegetable tissues (Schecht). A solution of alum in the proportion of 1 part of alum to 16 parts of water has been found to answer preserving all some substances. Ganass's solution, which consists of 1 part of acetate of alumina dissolved in 10 parts of water; solutions of common salt (1 part to 5 parts of water, with a little camphor), corrosive sublimate, per sulphate of barytes, arsenious acid, sulphate of zinc, and solutions of several other salts, have been recommended as preservative solutions, but their employment has not been always attended with the most satisfactory results.

Arseniated hydrogen gas has also been recommended for the preservation of animal substances, but it is not adapted for microscopical preparations.

**Canada Balsam.** — Canada balsam forms a most useful agent for mounting various substances; and the structure of many can only be clearly made out when they are examined in this menstrum.

In this method of mounting objects no cells whatever are requisite. The balsam should be pale and old. The glass slides must be warmed before the balsam is put on; and for this purpose the glasses may be held in a pair of tongs, or in a plate or pan of warm water. About a quarter of an ounce of balsam is to be spread upon a sheet of wax paper, which is covered with cork, and heated over a spirit-lamp or upon a brass-plate. The latter plan is the most convenient when several preparations are to be mounted at the same time, because they may be arranged in a row along the plate, and the balsam placed upon each slide as it becomes hot.

The Canada balsam may be heated after it is placed upon the slide, in order to allow the air-bubbles entangled in it to rise to the surface before it is applied.

The slide being warm, and the small quantity of Canada balsam sufficient to contain the preparation having been placed upon it, it must be gently moved about while the balsam is warm and quite fluid, until all the air-bubbles have floated to the surface, and collected together towards one spot. A pointed wire or needle should then be taken, and all the bubbles either drawn out upon the end of it.
which may be readily effected, or broken by the wire after it has been heated. In those cases in which the preparation is not detached from the glass slide upon which it has been allowed to dry, it is only necessary to place the drop of balsam upon it and gently warm it, following the usual precautions; afterwards the thin glass cover may be applied. When the preparation has been dried separately over the water-bath and cleaned, it may be taken in a fine pair of forceps, gently warmed, and carefully placed in the hot and perfectly dry balsam. After it has been thoroughly wetted by the balsam, and all adhering air-bubbles removed, it may be placed in the position it is intended to occupy. The thin glass cover, adapted to the size of the preparation having been previously cleaned and warmed, must then be taken in a pair of forceps and, after being placed in the balsam for a minute, allowed to fall gradually upon the preparation (beginning at one side), until it becomes perfectly wetted with the balsam. The glass may now be slightly pressed in order to force out the superfluous balsam, and the preparation allowed to cool.

We now proceed to give a few directions for the examination of particular objects, more especially animal tissues, as these of all others are the most difficult to manage. In the examination of transmission or of other tubular organs, it is frequently most desirable that injections should be made before they are submitted to the microscope. This operation requires great delicacy. A very small orifice in the injection tube, which must be adapted to the structure, must be employed. The fluid injected consists of size or gelatine, colored with various substances, as vermillion, merthiolate, and iodide of mercury, chromate of lead, indigo, Prussian blue, white lead, &c., according to the color of the structure to be examined.

The following general rules for injection are given by Dr. Baile:—Great attention should be paid to the cleanliness of all the instruments to be used in injecting. The syringe should always be kept scrupulously clean and in good order, and the injection tube, when not in use, to prevent the ingress of dust. Before commencing the operation, plenty of warm water should be at hand; and the subject should be allowed to soak for some time in a basin of hot water, before it is attempted to inject it, in order that it may be thoroughly warmed through. The temperature of the water must vary according to the degree to which the injection is required to be heated: if size and vermillion be used, the water need only be warm; but if melted wax be employed, the water must be so hot that the hand can scarcely be borne on it. The length of time which the preparation is allowed to soak must depend upon its bulk; and the water should be changed as soon as it becomes at all cool. With respect to the length of time which the subject be kept in the water, no absolute rules can be given. Generally, it may be remarked that we should not attempt to inject while the rigor mortis lasts. Many days may in some cases with advantage be allowed to elapse, particularly if the weather is cold, when the organ is removed from the body, and kept under a cool atmosphere after death. As a general rule, the more delicate the tissue, and the thinner the vessels, the sooner should the injection be performed. Many of the lower animals, annelids, molluscs, &c., and fishes, should be injected soon after death. In making minute injections of the brain, only a short time should be allowed to elapse after the death of the animal, before the injection is commenced. Injections of the alimentary canal of the higher animals should be performed earlier in the summer, and later in the winter.

When the preparation is warmed through, the injection properly strained, and the pipe fixed in the vessel, we may proceed carefully to inject, taking care that the injection is kept at a proper temperature, by allowing it to remain in the warm water-bath during the operation.

The air should be first withdrawn from the upper part of the vessel by means of the syringe, after which the stopcock is turned off and left attached to the pipe. The syringe is then filled with fluid, which should be done twice with warm water, is nearly filled with injection, which must be well stirred up immediately before it is taken. The syringe should not be quite filled, in order that the air in the pipe may be made to rise into the syringe through the injection. When the fluid is properly warmed, it is forced into the vessel. The end of the syringe is then to be pressed firmly into the upper part of the stop-cock, with a slightly screwing movement.

The piston is now very gently forced down by the thumb until the syringe has been nearly emptied, when the stopcock must be turned off, and the syringe refilled with warm injection as before.

Care must always be taken to keep the syringe in an inclined position, so that any air which may be in it may remain in the tube, and, further, that the injection should not be forced out, for fear of the inclosed air entering the vessels, in which case all chance of obtaining a successful injection would be destroyed.

After a careful examination of fluid has been injected, it will be necessary to use a greater amount of force, which, however, must be increased very gradually, and should only be sufficient to depress the piston very slowly. If too great force be employed, extravasation will be produced before the gas escapes from the cavities, and this is followed by an increased pressure, kept up for a considerable time, will cause the minute vessels to become slowly distended without giving way to any great extent. At the same time it must be borne in mind that extravasation frequently occurs at various points in a successful injection; but the longer this event can be kept off, the more likely we are to succeed.

In order to examine the structure of many tissues, it is necessary to obtain a section sufficiently thin to permit the eye to see distinctly. In other cases, the eye will not easily see the minute structure of the tissue may be submitted to examination in every part of the section. The difficulty of making thin sections of many textures is very great, and, to effect this object satisfactorily, a knowledge of certain mechanical and optical principles is indispensable. It is necessary to cut a thin section of a soft pulpy texture, which can scarcely be touched without injuring its delicate structure, and altering the position of its constituents; while, in other cases, we have to deal with a softer substance so hard that steel tools will scarcely scratch it, such as the enamel of teeth, fossil teeth, &c.

Previous to the examination of a tissue, boiling is frequently of service.

For instance, the fibres of which the crystalline lens is composed are best shown after boiling the lens in water. The branched muscular fibres in the tongue of the frog, and in other situations may be made out very readily by boiling the tissue in water for a few minutes; and then tearing up small portions with fine needles. Beautiful sections of muscular fibre can often be obtained after the texture has been boiled in water. Various glands and other textures often require to be boiled some time in water, in order to harden them sufficiently to cut thin sections; but in all cases the microscopical characters of the recent texture should be examined, as well as that which has been hardened by boiling. Small portions of tissue can be readily boiled in a test-tube over the spirit-lamp moments, and then tearing up small portions with fine needles. Boiling in water frequently enables us to tear up a tissue very readily with the aid of needles, and thus to demonstrate its structure. Occasionally it is found necessary to press the tissue, and rub parts of it together, before the soft pulpy portions can be got rid of. In this way we may demonstrate the supporting or trabecular tissue of the spleen, and the areolar and vessel tissue of the liver, &c. Thin sections of kidney, liver, and other organs, which are nearly soft, when the matrix is to be subjected to examination separately.

Thin sections of various tissues can frequently be obtained only by first drying the substance thoroughly, and then cutting off a thin shaving with a sharp knife. In this way the specimens of skin, muscles, &c., which are usually of a soft pulpy nature, are often most advantageously prepared. The tissue is stretched on a board with pins and then allowed to dry, when a very thin section can be cut off and examined in a microscope. In the case of the brain, it may be put in a boiling solution of alcohol, and then allowed to dry at room temperature, in which case, when subject to examination, it will often be found to have regained its first appearance. Portions of muscular fibre, the tongue, skin, and many other tissues, may be allowed to dry in this manner, and then we may with a sharp knife cut off the excess, which would otherwise could not be procured in any other manner. The drying may be effected in a warm room, or in a current of air. A high degree of artificial heat should be avoided.

When the inorganic portion of a tissue which we wish to
examine is not altered by exposure to a red heat, recourse may be had to ignition, in order to get rid of the animal matter. In this way crystals of carbonate and phosphate of lime, as well as silicious or organic matter, are separated from the organic material with which they were combined. The beautiful silicious shells of the Diatomacea may be separated from organic matter by a similar process. The ignition should be performed in a small platinum crucible, or upon a small iron plate. The crucible should be placed over a spirit-lamp. The carbonaceous residue must be exposed to the dull red-heat of a spirit-lamp for some time, until only a pure white ash remains, which will be found to contain the objects of our search in a perfectly clean state. The ash may be examined, and if necessary, treated, the ash should be treated with strong nitric acid, which will dissolve any carbonate or phosphate. The insoluble residue may then be washed and dried, and subjected to microscopic examination whilst immersed in turpentine or Canada balsam. In many cases this method is superior to that of boiling in nitric acid in order to remove the organic matter. Both processes may however be employed where only the silicious residue is wanted, but if we require the salts of lime, ignition at a dull red-heat is alone applicable.

In order to subject a portion of tissue or other substance to examination by transmitted light, the following plan is adopted:—One of the glass slides is carefully cleaned, and the thin section of tissue which has been removed by the aid of a knife or a scalpel is placed in the centre of a drop of clean water is then added, and the whole covered with a square of thin glass, also perfectly clean. If the under surface of the thin glass be gently breathed upon, it becomes perfectly transparent. The specimen may be unravelled with needles, or, if necessary, any other operation performed before covering it with the thin glass. If the substance be covered with too much soft pulpy matter, it may be slightly washed in water before being placed upon the slide, or a jet of water from the wash-bottle may be forced upon it. Thin sections will require to be laid flat upon the slide, with the assistance of needles and forceps.

Hard tissues require a different treatment. Here the great object is to examine thin enough for the object to be seen by transmitted light. Many hard substances, such as nail, horn, and dried animal textiles, may be cut with a strong knife, or with a mazer; an operation which is easily performed by placing the substance upon a piece of soft deal board, and, after cutting a smooth edge, removing a thin shaving, which may be examined dry or in fluid, or may be placed in Canada balsam, as occasion may require.

Such substances as bone, ivory, and fossilised rocks, should be cut in thin sections with the aid of a sharp saw. These sections should then be pared down to the necessary fineness upon a hone or smooth stone. This may be effected in the following manner.—The section, after having been cut, is immersed in a little water, and the ground surface before it can be subjected to examination. It may perhaps be as much as the tenth of an inch in thickness when the grinding is commenced, but by rubbing it for a short time upon a smooth stone it may be reduced to the proper degree of tenacity. Stones which are well adapted for this purpose are the 'Charley Forest' stones, the Turkey stones, or the Water of Ayr stones, about an inch or more in width, and six inches in length. Each of the four sides should be perfectly smooth. Other stones, even a piece of slate, answer also very well, and may be procured at much less cost. The stone is wetted with a little water, and the section rubbed up and down with the finger, or with a piece of cork or leather. A very good plan also is to immerse the section slightly in a piece of warm gum percha, which should extend only a very short distance beyond the edges. This is to be rubbed up and down upon the wet hone, water being added as required, till the surface is perfectly smooth, when the section is to be taken off, turned round, and ground down on the opposite side until it is sufficiently polished. The section may also be ground down expeditiously by rubbing it between two hones. If very thick, it will be better to reduce it somewhat with the aid of a flat file before commencing the grinding. After being ground a little thinner, the section may be placed in the microscope, when numerous dark lines will be found all over the surfaces; these must be removed by polishing. The deepest of the scratches may be obliterated by fusing the specimen upon a very smooth part of the hone quietly.

Teeth require a little more attention than other hard sub-

stances. They should be first ground down upon a lapidary's wheel, or upon a dentist's emery wheel. Sections can also be readily cut with a diamond saw (an iron wheel, the edge of which is sharpened when it is dull) by laying the specimen upon a metal foil. The thin section is now to be soaked for a short time in ether to remove the fatty matter, and then allowed to dry. It is to be subjected to examination in the dry way, moistened with water, turpentine, or Canada balsam, and the different appearances in each case should be carefully observed.

The cartilaginous basis is to be examined also in this sections, which may be cut either before macerating in acid, or afterwards, when the more readily soluble part of the acid will become soft in four or five days, when thin sections of different parts may readily be cut with a sharp knife. The dentinal tubes may be isolated from each other by longer maceration in acid, and afterwards by soaking for a few days in nitric acid. A strong spirit-lamp may be employed in this investigation to cut the thin section before maceration in acid, or to macerate the tooth until moderately soft, and then remove a thin section, which is to be further exposed to the action of the strong acid. A mixture of sulphuric and hydrochloric acids has also been recommended.

The examination of fluids does not require so much art as that of solid matters. Where it is wished to examine the whole of the contents of a fluid, all that is necessary is to place the fluid into a wash-bottle, or, if a vessel of thin glass. It frequently happens however that it is the matter suspended in a fluid that is desirable to examine. Under these circumstances the fluid should be placed in an ordinary vessel, and it is then advisable to set the supernatant liquor should be poured off, and a drop of the deposit conveyed to the glass slide. In other cases a pipette may be made use of to draw up the deposit from the bottom of the test-tube or other vessel in which it may be held. In examining water to ascertain the nature of the deposit in a wash-bottle, or small muslin-bag or net may be employed, through which the water may be poured, and the contents of the bag placed on the slide. In this way the 'Dusmilids' and some of the larger forms of Infusoria are best procured for examination. The nature of deposit is very variable, and the following plan will be found of practical utility. After allowing the lower part of the fluid which has been standing to flow into the pipette as above described, and removing it in the usual manner, the finger is applied to the orifice, in order to prevent the escape of fluid when the upper orifice is opened by the removal of the finger. The upper opening is then carefully closed with a piece of cork. Upon now removing the finger from the lower orifice, the fluid will not run out. A glass vessel covered under the pipette, which is allowed to rest upon it for a short time. It may be suspended with a piece of string, or supported by a small retort-stand. Any traces of deposit will subside to the lower part of the fluid, and the amount of necessity be collected in a small drop upon the glass slide, which may be removed and examined in the usual way.

Another plan is to place the fluid with the deposit removed by the pipette in a narrow tube, closed at one end, the end of which is rather less than a quarter of an inch in diameter. This may be inverted on a glass slide, and kept in this position with a broad elastic India-rubber band. The deposit with a drop or two of fluid, will fall upon the slide, but the escape of a further quantity is prevented by the nature of the arrangement. Amongst the fluids of the human body which may with advantage be submitted to examination with the microscope, there is none of more importance than the urine. This fluid being the great abode which nature employs to rid the system of the used-up and effete matter of the body, becomes an index by which the completeness, redundancy, or insufficiency of this function may be examined. The following hints for the examination of this fluid will be found useful. The urine which is to be studied should be collected in sufficient quantity, in order to obtain sufficient of the deposit for examination.

In all cases the urine should, if possible, be examined within two hours after its secretion, and, in many instances it is important to institute a second examination after it has been allowed to stand for 24 hours. Some specimens of urine pass into decomposition within a very short time after they have escaped from the bladder; or the urine may even be drawn from the bladder actually composed.

In other instances, the urine does not appear to undergo
decomposition for a considerable period, and may be found clear, and without any deposit a day or two, or even longer, after it has been removed.

In those cases in which a large quantity of lime is present, we shall find that the deposit increases in quantity after the urine has stood some time. The latter salt is frequently not discoverable in urine immediately after it is passed, but makes its appearance in the course of a few hours; depending upon a kind of acid fermentation, which has been the subject of some beautiful investigations by Scherer.

In order to obtain sufficient of the deposit from a specimen of urine for microscopical examination, we must place a certain quantity of the fluid in a conical glass, in which it must be permitted to remain for a sufficient time to allow the deposit to settle into the lower part.

Urinary deposits often require to be examined with different magnifying powers, those which are most frequently used being the inch and the quarter of an inch. Large crystals of lactic acid are often readily distinguished by the former, but crystals of this substance are sometimes so minute that it is absolutely necessary to use high powers. Opaque hydroxide of lime is frequently found in small that they cannot be seen with any power lower than a quarter; and, in order to bring out the form of the crystals, higher magnifying powers than this are sometimes necessary. Spermatozoa and erythrocytes often become ruptured and disappear very quickly. In these cases, an eighth of an inch objectglass will be of advantage. The casts of the tubes, epithelium, and the great majority of urinary deposits, can, however, be very satisfactorily demonstrated with a quarter of an inch objectglass.

In the investigation of these deposits which are prone to assume very various and widely-different forms, such as lactic acid, it will sometimes be necessary to apply a microscope, and, in some of the most minute tests, to use the nature of the substance under examination can be positively ascertained.

The urine is very liable to the introduction of foreign substances. A paper on this subject by Dr. Beale will be found in the first volume of the Quarterly Journal of Microscopical Science, and an addition to the same, occasionally found by Dr. Beale—Fragments of human hair; cat's hair; hair from blankets; portions of feathers; fibres of wadded of various colours; fibres of cotton of various colour; fibres of flesh; potato starch; rice starch; wheat starch, broad-crumbs; fragments of leaves, or separated spiral vessels and cellular tissue; fibres of coconuts or other wood, etc. The crystals of the urine are usually found in the course of half an hour, or even sooner if it be diluted with a little water or alcohol. Dog's blood also crystallises in the course of a short time upon the addition of a little alcohol. Human blood also crystallises in the addition of a very large quantity of water at a very low temperature. The crystals form more readily in daylight than in the dark, but most rapidly when the slide is exposed in the light of the sun.

Ginneas-pig's blood crystallises in the course of half an hour, or even sooner if it be diluted with a little water or alcohol. Dog's blood also crystallises in the course of a short time upon the addition of a little alcohol. Human blood also crystallises in the addition of a very large quantity of water at a very low temperature. The crystals form more readily in daylight than in the dark, but most rapidly when the slide is exposed in the light of the sun.

It is obvious from what has been said above that the microscope is one of the most important instruments of the physician, and research that is of the highest importance to the characters of these bodies the student should be perfectly familiar as soon as possible; and, as they may be obtained without the slightest difficulty, this is easily effected. For the nature of the deposits found in the urine, see the article Urine.

The examination of the other fluids of the animal body presents little difficulty. Next to the urine that is of most importance. In order to examine the blood, a small drop is placed upon a glass slide, and covered with thin glass, which is to be prepared until a very thin, transparent, and almost colourless stratum only remains. If in this manner the individual globules cannot be seen distinctly, a little syrup or serum must be added; but it is better to avoid the addition of any fluid, if possible. Upon carefully focusing, the red globules will appear to present a dark centre and light circumference, or the reverse, according as the focus is altered, and here and there a white corpuscle may be observed.

In taking blood syrups are added to a drop of blood, the corpuscles will be found to have become flatter from exposure of a part of their contents; while, on the other hand, if placed in water, they become spherical from endosmosis, and ultimately have a spherical density to that in the interior of the corpuscle; and in this manner, as Dr. Rees expresses it, we may take the specific gravity of a blood-corpuscle, if we ascertain the specific gravity of the solution which has been added to the blood.

Acetic acid causes the membrane of the corpuscles to become more transparent and clear, and to swell up from endosmosis. After the application of this reagent, the blood-corpuscle may be scarcely visible, but the membrane cannot be dissolved by it. Strong hydrochloric and nitric acids do not dissolve the globules; with the latter re-agent the outline is often rendered darker and thicker, while the entire globule becomes smaller. The corpuscles are entirely soluble with the acids of the gastric juice, and after remaining in acid urine for some time a similar change occurs; hence the black colour of blood which has been defused into the urine, and the dark smoky bus of acid urine containing blood.

We have before spoken of the crystals to be obtained from the blood. These crystals are very readily obtained by diluting blood with water. A drop of blood may be placed upon a glass slide, and after the addition of a drop of water, alcohol, or ether, the whole should be lightly covered with thin glass. A hair, or a small piece of thin paper or wood, may be placed between the glasses, in order that a stratum of fluid of sufficient thickness may be retained. Whenever it is possible, it is preferable to use distilled blood. Often the corpuscles and a little serum may be removed from the clot by firm presssure, and from this very perfect crystals may frequently be obtained. The blood-corpuscles may be obtained and preserved in this manner, and crystallised as the solution gradually becomes concentrated. The time which elapses before crystallisation takes place varies from an hour to several hours or days in different species of blood. Crystals may also be obtained in a similar manner from the drops of blood.

The form of the crystal often varies slightly in the same specimen, but the blood of different animals yields crystals of very different forms. The prismatic form is most commonly before; cubic, octahedral, and cubo-hexagonal; and, as usual, it is frequently seen in the preparations of urine, that is, in the urine of the guinea-pig, while six-sided are formed in the blood of the squirrel, mouse, and some others. Teichmann has succeeded in obtaining crystals from the blood of fishes. Sometimes they are seen in a very large quantity of water at a very low temperature. The crystals form more readily in daylight than in the dark, but most rapidly when the slide is exposed in the light of the sun.

The crystals of the urine are usually found in the course of half an hour, or even sooner if it be diluted with a little water or alcohol. Dog's blood also crystallises in the course of a short time upon the addition of a little alcohol. Human blood also crystallises in the addition of a very large quantity of water at a very low temperature. The crystals form more readily in daylight than in the dark, but most rapidly when the slide is exposed in the light of the sun.
part of the genito-urinary mucous membrane, or to more general disturbance in the changes which take place in primary and secondary assimilation.

Fatty Degeneration.—Of late years the remarkable changes which take place, and which have been described under the name of Fatty Degeneration, in some of the highly nourished and well-fed animals, the gradual change of which their properties become changed, and their functions impaire, or altogether destroyed, have been undergoing careful investigation by a vast number of highly-talented investigators.

The recent discovery of a state of fatty degeneration affecting the arteries of the brain, in the majority of cases of apoplexy, by which the strength of their coats becomes deteriorated, and their elasticity entirely destroyed, would lead us to think that this disease is an independent reaction upon complicated changes affecting nutrition, than upon the presence of a condition of plethora or hypersemia, as was formerly supposed and acted upon.

The connection between fatty degeneration of the margin of the cornea (arcsus senilis), and similar changes taking place in the muscular tissue of the heart (a subject which has been carefully investigated by Mr. Canton), or in the cerebral vessels, must be regarded with great interest by every philosophical mind.

The microscopical examination of the matters vomited in certain cases has proved to us that the presence of minute fungi, originally discovered by Professor Goodeir, and named by him Sarcina Ventriculi, occurs in connection with the chylous matter in the stomach. These remarkable cases are much more frequently met with than was formerly supposed, and form an exceedingly interesting class of diseases. [Entophyta, S. 2.]

The Microscopic Growth.—The microscope has many times afforded important aid in the diagnosis of tumors, although it has certainly failed in many instances; which circumstance has been brought forward by some, as an argument against its employment altogether. After careless and hasty examination, the best observers have failed in deciding as to the nature of a particular tumor submitted to examination; and they have been unable to pronounce as to its malignant or non-malignant character.

On the other hand, not unfrequently this question has been positively and correctly answered in the affirmative or negative, and therefore it would surely not be right altogether to discard the use of an instrument which, although eminently useful in many instances, is not infallible; for it would appear to be the opinion of some, that the use of the microscope ought to be altogether abandoned in the diagnosis of tumors.

The discovery of Imposition the microscope is invaluable. This has naturally followed that, in consequence of the frequency with which urine is usually submitted to examination, patients often resort to various expedients to deceive the practitioner. Perhaps flour, starch, sand, and milk are more frequently employed for this purpose than any other substances; the microscope, however, is so powerful as to enable any one to detect the first three. If milk be added to urine, the mixture may very readily be mistaken for a specimen of the so-called chylous urine. Although a considerable quantity of fatty matter is present, in either case this fatty matter exists in a very disintegrated state. In milk we find the oil-globules, so characteristic of this fluid, while in true chylous urine not a single oil-globule can be found, although the specimen may contain a large quantity of fatty matter in a more or less state.

<MDM> Larva of the Blow-Fly in Urine.—A specimen of urine containing several bodies of about half an inch in length, and of a rounded form, was once sent to Dr. Todd for examination. The bodies in question looked not unlike the larvae of some large fly, but, as it was confidently affirmed that they were passed by the urethra of a gentleman, the accuracy of this view of their nature was doubtful.

Upon placing a portion of one of them under the microscope, we observed no trace of any trace of the class of insects) were observed in considerable numbers; and the circumstance alone enabled me to say positively that they were not Entozoa, and that they could not have been passed in the manner stated. They were afterwards proved to be the larvae of Sarcina Ventriculi.

The claws of Entozoa and portions of hydatid cysts occasionally are seen in the urine, spuits, &c., upon submitting portions of these fluids to microscopic examination, proving beyond a doubt the existence of tapawas. [Entophyta, S. 2.]

Substances passed by the Bowels.—If the patient have a good knowledge of the use of the microscope, he can often ascertain the nature of substances passed from the alimentary canal; and by the aid of this instrument be can often discover the true nature of substances which, to the unaided eye, only present most doubtful characters. Considerable perplexity has arisen from the presence of bodies in the stools of patients, which afterwards turn out to be portions of almonds, potatoes, or other substances. In the examinations of the food, have resisted the process of digestion, have been met with in the faces, and mistaken for small intestinal worms, which they much resemble when examined by the unaided eye. Upon being subjected to a microscopical examination their true nature was readily discovered.

In Medical-Legal Inquiries the microscope has often afforded valuable aid. The distinction between blood-spots and red stains produced by fluids resembling blood in color—blood in the urine and that of animals—and the detection of spermatozoa in cases of rape, need only be added as examples of the importance of the microscope in such investigations.

For Detecting Impurities in Food and Drugs the microscope is of immense importance, and there are several other purposes to which it may be applied.

MICROSCOPY: [DURHAM; YORKSHIRE.]

MIDDLESBROUGH. [YORKSHIRE.]

MIDDLETOWN. [KENTUCKY.]

MIDDLETOWN. [DURHAM; LANCASHIRE.]

MIDDLETOWN [MINNESOTA. [MINNESOTA.]

MIDDLETOWN. [CONNECTICUT.]

MIDDLETOWN. [NEW JERSEY.]

MIDDLETOWN, county of Cork, Ireland, a port- and market-town, and the seat of a Poor-Law Union, is situated near the head of the north-eastern branch of Cork Harbour, is 81° 55’ N. lat. 8° 10’ W. long., 134 miles E. from Cork by road, and 1734 miles W. from London. The population in 1851 was 3676, besides 2334 inmates of the workhouse. Middletown Poor-Law Union comprises 10 electoral divisions, with an area of 109,268 acres, and a population in 1851 of 44,049.

This consists mainly of a spacious and well-built street between the Avonachara and Rosboro rivers, terminating at each end in a bridge. In the town are a neat parish church, a Roman Catholic chapel and nunnery, a Free Church, a public library founded by Mr. R. C. Pritchard, 1335 scholars in 1852, two National schools, a court-house, a market-house, a bridewell, a fever hospital, and a distinct dispensary. There are also distilleries, breweries, con-
stores, and flour-mills. Vessels of 200 tons ascend to Ballylick, within half a mile of Milten — and at the port of Ballincurra, about a mile below the town, large shipments are made of corn and other provisions. Quarter and petty sessions are held in Milten. Milten was on May 14th, July 5th, October 10th, and November 22nd. The town and neighbourhood are the property of Viscount Milten.

MILBURN. [Somersetshire.]

MILITARY AND NAVAL FORCES. Under 'Great Britain,' in Penny Cyclopaedia, vol. xi., p. 420, the state of the army and navy of the United Kingdom, in 1858, was given. Since that period, partly in consequence of the deficiencies made apparent during the war against Russia, several important regulations have been introduced into the army. To the branches of the Artillery and the corps of Engineers, commissions were thrown open to competitive examination, with a marked success. After a certain time, not yet fixed (April, 1859), the first entrance to these corps is to be made at Sandhurst Military College, but it would appear that, with very slight restrictions, these corps, as well as staff appointments, will still be open to public competition. The competitors must not be less than 16, nor more than 18, years of age, they must have testimonials of responsibility, and they will have to be nominated by the Commander-in-chief, before they can be received for examination.

To the main body of the army facilities have been afforded for frequent fighting for the soldiers, and promotions from the ranks. The use of the Minie and Enfield rifles have been generally adopted throughout the army, and prizes have been instituted for the encouragement of skill in their use. Some alterations also have been made in the clothing and equipment of the soldiers, which, as far as they have gone, have been improvements, but which might be judiciously extended. A permanent camp was also formed at Aldershot, near Bagshot, in 1855, where field operations could be effectively performed, and another in Ireland. Also, in consequence of a medical report showing the fearful mortality in the army arising from sickness, an investigation was ordered, which resulted in showing that the main cause of a mortality which considerably more than doubled the average rate, and very much exceeded even that of the most deleterious and dangerous trades, was the ill-constructed and crowded state of the barracka. In March, 1858, General Peel, the Secretary for War, announced that surgeons had been appointed to examine the barracks, and that prompt means would be taken to remedy these evils.

The number of officers, non-commissioned officers, and rank and file, voted for the effective service of the United Kingdom for the year ending March 31, 1857, the close of the Russian war, was 24,757,150, exclusive of the 10,000 in the East Indies, who amounted to 30,263; the number of the non-effective service was 2,000; the estimated charge was 34,996,504l.; an increase of 30,373 men, and of 6,288,007l. of charge, over the preceding year. The revised estimate was subsequently reduced to 250,340,024l.

For the year ending March 31, 1858, there were voted 186,756 men, with 11,786 horses, a decrease of 119,920 men from the preceding year. The troops in the East Indies had been increased to 30,197, with 2,812 horses.

For the year ending March 31, 1856, the estimate was as follows —

The amount voted for the year ending March 31, 1857-8, was 11,443,236l.; for 1858-9 it was 11,750,000l. Of this in the first year 4,380,017l., and in the last 4,361,057l. were expended on regimental and staff payments and allowances, but 800,000l. in the last year was to be paid by the East India Company on account of the excess of numbers sent to India.

The amount voted for the Embody Militia for the year ending March 31, 1859, was 650,000l. and for Volunteer Corps, 80,000l.; for 1858 the amount had been 58,829l.

The sum expended on the effective service in the army in 1857-8 was 9,221,360l.; the estimate for 1859-9 was 9,286,319l.; on the non-effective (pensions, rewards, and allowances), 2,291,675l. and 2,940,682.

In the Navy much attention has been given to instructing the seamen in the working of great guns. This has been eminently successful, and the precision and rapidity with which they can now be directed and discharged has added materially to their efficiency for destructive purposes.

In 1857 the total navy consisted of 260 sailing vessels, carrying 67,272 guns, and 205 steam vessels carrying 6,050 guns, besides 150 gun-boats. These were manned by 45,776 men, including officers, and there were in addition 16,000 marines.

In January 1858 there were in commission 645 vessels of various sizes, sailing and steam-propelled vessels, mounting 10,716 guns, and 130 steam-cum-sail-ship and 240 ships of war, 5 mounted 131 guns each, and 22 others mounted from 101 to 120 guns each. The arming of vessels has however undergone considerable modification, the chief objects aimed at now are facility of motion in the ships, and weight of metal and length of range.

The flag officers in active service in January 1858 numbered 21 admirals, 27 vice-admirals, 61 rear-admirals, 350 captains, 517 commanders, 1,105 lieutenants, 345 masters, 1,019 mates, 1,030 chargers, 127 engineers, 227 surgeons, 257 assistant-surgeons.

Of the Royal Marines there are 104 companies, of which the total strength is estimated at 15,000. They are commanded by 3 generals, 3 lieutenant-generals, 5 major-generals,
4 colonels commandant, 5 colonels and second commandants, 19 lieutenant-colonels, 120 captains, 176 lieutenants, and 88 second lieutenants. In the latter there are 304 officers of Royal Marine Artillery, with 1 colonel and second commandant, 2 lieutenant-colonels, 14 captains, 37 first lieutenants, and 9 second lieutenants.

In the Mediterranean on the navy for the year ending March 31, 1857, was 14,694,614, an amount less by 1,904,100 than that of the estimate of the gross amount. The vote for 1858-9 was for 44,380 seamen, including coast-guards, &c., and 15,000 marines; the estimate of the expendable was 70,900,000, including the effective and non-effective services.

The military and naval forces of the principal foreign countries for 1857 (where not stated to the contrary), are given as follows in the 'Oeche Almanach.'

*The Netherlands amounted to 55,565 men, of whom the infantry, including the staff, number 43,853 men; the cavalry 4490; the engineers 695; the artillery 8687; a corps of portoliers, numbering 213; and 3 cavalry regiments of Zouaves; in all, 19,965,298. There were altogether 332 guns; there were 2 ships of the line, 6 sailing and 14 steam frigates; there were 50 mortar and gun-boats, and other small vessels. The total population of the Two Kingdoms was 5,211,113, in 1856.*

*In Austria there were 56,495 men, the infantry, and 12,894 men, the artillery, altogether 59,389 men; there were 3 ships of the line, 4 frigates, and 2 gun-boats, and 14 steam-elephants. The number of gunners and engineers was 7,351.*

*The military forces of the United Kingdom of Italy amounted to 136,926 men, with 956 officers of artillery, and 1,265 engineers; there were also 9,700 men, veterans in retreat, and others, with a reserve of 12,000, making a total of 31,845 men. These were independent of 17,353 men, forming the armed forces of its foreign possessions. The navy consisted of 28 vessels, of which 5 were disarmed, and 6,116 men, lieutenants, and military engineers; there were also 3,964 men, veterans in retreat, and others, with a reserve of 4,966, making a total of 31,816 men. The following were the forces in the various countries:*
303 provincial guards in the Canaries; a total of 112,609 men, with 11,980 horses. There is also a corps of carabiniers consisting of 75 companies, of which 11 are cavalry, which form the frontier guard. There are likewise a considerable number of forces in Cuba, and other foreign possessions. The navy consists of 51 sailing ships, and 48 steam-vessels; there were 3 ships of the line, 10 frigates, ranging from 42 guns to 2 guns; 5 corvettes, 11 frigates, &c., the whole manning 1100 guns. There are also a large number of gun-boats, &c., with the total number of 144,013 men. The enrolled troops form 3 regiments of infantry, 2 of cavalry, and 3 of artillery, and number altogether 10,702 men, exclusive of officers; the cantioned troops of the rest of the part of their service total 7621 men; and the troops raised by conscription number 95,295 men. Norway had a military force of 11,924 infantry, 1070 cavalry, 1330 artillery, with 9160 of the landwehr. The navy possessed 897 vessels of various sizes, consisting of 703 officers' vessels, 450 cannon; of these 3 frigates, 4 corvettes, 122 gun-boats, &c. The maritime conscription amounted to 46,000 men. The united population of Sweden and Norway in 1855 was 5,076,058.

Of Switzerland the army consisted of 108,000 men, of whom 76,000 formed the regular army, and 32,000 the reserve. The regular army comprised 74 battalions of infantry, 43 companies of riflemen, 39 companies of cavalry, 40 companies of artillery, and 9 companies of engineers. The population of Switzerland in 1850 was 1,417,774.

Turkey had an army comprising 100,800 infantry, 17,300 cavalry, 7800 artillery, with 5300 additional in fortresses, 1600 engineers, 16,000 detached troops in Candia, Tripoli, and Tunis, which made the total number 68900 on a reserve of 128,680 men. The navy in 1853 comprised 70 vessels, manned with 34,000 seamen, and 4000 marines. The population of Turkey in 1844 (the latest taken) was 30,600,000.

With the peace establishment, 6149 infantry troops, 172 cavalry, and 1562 artillery, [engineers, &c., making a total of 9663 men; on a war establishment these can be raised to 22,016. The population of Wurtemberg in 1855 was 1,069,720.

The United States of America possessed an army composed of 1 corps of engineers, 5 regiments of cavalry, 4 regiments of artillery, and 10 regiments of infantry. The whole effective force was 16,502 men; but in addition, the militia number 54,000. At this date, this army consisted of 74 vessels, mounting 2244 guns. There were 10 sail of the line ranging from 120 to 84 guns; 13 frigates ranging from 60 to 60 guns, most of the guns of large calibre, and many of the vessels propelled by steam of most excellent construction. The population of the United States in 1850 was 37,601,708.

MILITARY PUNISHMENTS. The policy which has been pursued of late years in modifying the punishments prescribed by the military laws, and in throwing off the collar, has been extended to those which may be inflicted by courts martial for military offences. One material alteration consists in the limitation of corporal punishments; the utmost extent to which this could be carried has been described in a previous part of this work, which would it appear, cannot serve out of the kingdom except with the consent of Parliament (18 & 19 Vict. c. 1).

MILLER, HUGH, an eminent geologist. He was born at Cromarty, in the north of Scotland, on the 18th of October, 1802. He was descended from a humble family, who had been long known in the parish of Cromarty as sailors. His father became eventually possessed of a small vessel of his own, in which he was lost, whilst Hugh Miller was yet a child. In a short time he was sent to school, and began to show distinguished for his fondness for poetry and poetical composition. At this time he was a large reader, and placed under contribution the libraries of the parish. In this way he laid the foundation of an extended knowledge of literature, which availed him in after life. But the most important part of his education consisted in the natural history instruction he received from an uncle who had acquired a taste for the observation of natural phenomena. Whatever might have been his aspirations, he was obliged to content himself with learning the trade of a mason. This occupation, however unexpectedly fostered the taste he had acquired for the study of natural history; and whilst hewing blocks of stone in the quarry, he diligently studying the traces they exhibited of their past inhabitants. He then resolved to himself to become the historian of the Old Red-Sandstone, amongst the rocks of which he principally worked. His first literary efforts were not however directed to geology. He was early devoted to the muses, and was induced, by the failure of his first attempt to become a poet, to confine himself to writings of a more prosaic character. His other works, however, are suffices to publish a book of poetry. This work, though it failed to give him a position as a poet, drew towards him the attention of friends, which resulted in his giving up his mason's employment and becoming an owner of land in his native town. This appointment occupied him more leisure for literature. He became a frequent contributor to newspapers, more especially the 'Inverness Courier'; but his first distinct prose publication was entitled 'Scenes and Legends of the North of Scotland.' Although the subjects of this work was only of local interest, the purity of its style and the thought and feeling thrown into the subject discussed, made it a popular work, and several editions have been printed.

With naturally strong feelings, and a power of writing rapidly and impressively, it might be expected that a man in Mr. Miller's position would enter into the great discussion which terminated in a rupture of the Scotch church. His views were, however, by no means such as to enable him to take part in the discussions of the Scotch people to the Right Hon. Lord Brougham and Vaux, on the opinions expressed by his lordship in the Anchariterar case.' This letter, which was referred to by Mr. Gladstone in his 'Church Principles,' as the 'elegant and most magnificent,' was written in answer to a letter from Lord Brougham, upon the author the attention of the Free Church party. They had long felt the need of an organ, and the man had at length appeared who was capable of undertaking its conduct. The 'Witness' newspaper was started, and Mr. Miller was invited to accept its editorship. This paper was published twice a week, and conducted with great ability by Mr. Miller to the day of his death. Although never falling in the political and public departments, he found time to carry out the projects which he had so long entertained, and which were described in a series of papers in the 'Witness.' These papers excited the surprise and admiration of the geologists who assembled at the first meeting of the British Association in Glasgow in 1840. Sir Charles Lyell, Sir Roderick Murchison, and Dr. Buckland, were amongst those who admired his astonishment at the amount of new matter which was thus for the first time brought before them. Professor Agassiz, who was also present at this meeting, named one of the papers as the best he had ever read. After the death of Miller, after its discoverer. These papers were afterwards published in a volume, 'The Old Red Sandstone, or New Walks in an Old Field.' This work is written in a style remarkably pleasing, and treats of the great facts of geology in a peculiarly attractive manner, and will remains one of the most popular works on geology in the English language. Its scientific merit consists in the description of a number of new fossil forms of animals belonging to a formation which had, up to that time, been unknown.

3 G 2
MILITATION, been regarded as almost destitute of the remains of animal life.

Mr. Miller had never visited England. He now made a journey to London, and with pen in hand made notes of what he saw and felt. These notes he published on his return under the title of 'First Impressions of England and Its People.' This work has also been admirably compressed, and is entitled, 'Vestiges of the Natural History of Creation,' was published in 1844, which excited much attention, and not least in the religions world. The discovery of a fish and a plant in the old red sandstone furnished Mr. Miller with arguments against the views of the author of the 'Vestiges.' These he embodied in a work entitled 'Footprints of the Creator, or the Astrogeology of Stromness.' It embraced a general view of the natural history of creation, and is regarded as an able exposition of the views of a most distinguished point of view. Like the author's other works it has had a large circulation.

Mr. Miller also published other works and papers on geology. In 1848 he published 'The Geology of the Bass.' At the meeting of the British Association at Edinburgh in 1840 he read a paper on "certain peculiarities of structure in some ancient Ganoidea (Fish)." At the meeting of the Association at Glasgow in 1855 he gave an elaborate account of the Fossil Flora of Scotland. He also lectured in Edinburgh on geological subjects. Mr. Miller's death was sudden and very startling. On the morning of the 24th of December, 1866, he was found dead in his room, shot through the body, and under circumstances which left no doubt that he died by his own hand. He had been lately engaged in writing his editorial labours, at a work called 'The Testimony of the Rocks,' and his brain, already diseased, had become strongly excited. An old habit, that of sleep-walking, bad returned upon him. He had, through fear of robbers, kept a loaded pistol in his room; and with this pistol, in a paroxysm of his disease, he put an end to his life. The work which he had thus completed on the day preceding his death, was shortly afterwards published, and had a large sale.

Mr. Miller's death caused a most painful excitement. Few men have occupied a higher position in the estimation of his countrymen. He was a noble example of what self-education can do for a man, and whether regarded as the fearless and independent writer, or the man of literature and science, his character must claim the respect and admiration of posterity.

MILLER'S THUMB. [COTTONUS.]

MILTHORPE, OR MILNTHORPE. [WESTMORELAND.]

Milkweed. [Asclepias垒.

Mr. Birket was born in 1776. He received a good education, became particularly skilful in mathematics, and acquired an extensive knowledge of languages. When about forty years of age he was appointed an actuary of the Sun Life Assurance Office, a situation in which he continued for upwards of thirty years. His 'Treatise on Annuities,' published in 1815 in 2 vols. 8vo, is one of the universally-acknowledged authorities on the subject of life assurance, for the calculations of which he invented and described a new system of notation. Mr. Milne had also paid some attention to botany, and was said to have possessed one of the best botanical libraries in London. His uniform courtesy gained him general esteem, and his information and assistance were readily given wherever they might serve a useful purpose. He died Jan. 4, 1851, having unfortunately become mentally incapacitated for fulfilling his official duties a few years earlier.

MILTON ABBAS. [Dorsetshire.]

MIMOSA, a genus of Plants belonging to the natural order Leguminosae. It has polygamous flowers; petals 4 or 5, connected together into a 4- or 5-cleft funnel-shaped corolla; stamens inserted in the base of the corolla; or in the stipe of the ovary. In the petals of the corolla, equal in number to the lobes of the corolla, or double or triple that number; legume-compressed, flat, 3- or many-jointed; joints one-seeded; ribs permanent; stipules petiolar; leaves bipinnate, with one or more pairs of pinnae, each pair of which is perforated by a number of pairs of hair-like hairs compressed or white, dotted, or pinnately cleft. The leaves are frequently sensitive to touch, as in the Sensitive Plant. The species are very numerous.

M. sensitiva, the Sensitive Plant, has prickly stems and petioles, and is dotted, when patted, but not glabrous above. It is a native of Brazil. The flowers are rose-coloured and tetraspermous. The leaves are sensitive to touch, but not so much so as the following species.

M. pudica has a prickly herbaceous stem, with the petals and peduncles more or less beest with stiff hairs or bristles; leaves somewhat digitately pinnate, with 4 pinnae, each pinna bearing many pairs of linear leaves. It is a native of Brazil. The flowers are of a very delicately fragrant, and it is found in gardens under the name of Sensitive Plant, the leaves falling on the slightest touch. The roots of this plant and its allies emit an offensive smell, resembling the odour of a sewer at the time of impending rain. The legumes of M. saponaria, a considerable article of commerce in India on account of their saponaceous qualities. [SENSITIVE PLANTS.]

MIMOTOMIC ACID. [CHEMISTRY. S. 2.]

MIMUS, a genus of Plants belonging to the natural order Sapotaceae. It has a cinch 6- to 8-parted; segments disposed in a twin order; corolla with a double row of segments; fruit with 20 segments of which are either entire or divided, the inner row containing 6 or 8 entire segments; antheriferous stamens 6 or 8, opposite the inner segments of the corolla, alternating with many sterile ones; ovatum 6- to 8-celled; berry 1- to 2-seeded; fruitlets are elliptic or orbicular, quite-enlarged glabrous coriaceous leaves, and axillary fascicles of 1-flowered pedicels. The flowers are small and white; the fruit edible.

M. Ellioti has ovate-lanceolate or oblong leaves, acuminated, glabrous; pedicels many together, shorter than the petals, which are glabrous. It is a native of the East Indies, where it is much planted on account of its fragrant flowers, which come out chiefly in the hot season. A fragrant water is distilled from the flowers. The seeds yield an abundance of oil in request for painters. The leavers are said to produce an extraordinary noise when bruised.

M. Kagi has ovate leaves, very blunt, silvery or hairy beneath, hardly three times as long as the petioles, corolla 12-lobed, with 12 corolla filaments, touching the leaves and frequently sensitive to touch, as in the Sensitive Plant. The species are very numerous.

MINERALOGY, according to the definition given by Kirwan, is the art of distinguishing mineral substances from each other. It may be regarded both as a science and an art. As a science, in reference to the knowledge requisite in supplying accurate descriptions of minerals, and forming what may be termed a natural classification; and as an art, in reference to the arrangement of the descriptive character for the purpose of afterwards distinguishing minerals from each other.

Mineralogy then must be considered as including the
The chemical composition of bodies, and an account of their external or physical properties. Both are requisite, for substances occur which agree in their chemical composition, and exhibit differences in their external characters; while there are other bodies which differ in their chemical constitution, but agree in their external properties.

Various methods of arrangement of minerals have been proposed by different authors. According to Werner, minerals were divided into the four classes of earthy minerals, saline minerals, inflammables, and metals; Karsten classed them under the heads of earths, salts, combustibles, and metals; Hauy divided minerals into scidiform earthy substances, earthy substances, non-metallic combustible bodies, metallic bodies, and substances not sufficiently known to admit of classification, rocks, and volcanic products. In Phillips's 'Elements of Mineralogy,' the classes are earthy minerals, alkaline-earthy minerals, acids, acidiferous earthy minerals, acidiferous alkaline minerals, native metals, metaliferous minerals, and combustible minerals. Beralius attempted a strictly chemical classification of minerals: he has, however, candidly admitted that considerable difficulties attend this method, owing, in part, at least, to the uncertainty which exists as to what are the essential and what the accidental constituents of a mineral.

The following is the arrangement of Dufrenoy, as given in Professor Ansted's 'Elementary Course of Geology':—

Class I.—Simple bodies, or Binary Compounds never bases, generally essential ingredients in combinations, and serving as proximate elements.

Class II.—Alkaline Salts.

Group 1. Salts of Ammonia. 2. Salts of Potash.

Class III.—Alkaline Earths, and Earths.

Class IV.—Silicates.

Group 1. Anhydrous Aluminous Silicates.

1. Hydrous Aluminous Silicates.

2. Silicate of Alumina and Lime, or their isomorphs.

3. Aluminous and Alkaline Silicates, and their isomorphs.

4. Hydrous Aluminous Silicates with Alkaline and Base, and their isomorphs.

5. Non-aluminous Silicates.

a. With Lime as a base.

b. With Zinc as a base.

c. With several bases.

7. Silico-Alumina.

8. Silico-Fluorites.

10. Silico-Titanates.

11. Silico-Sulphates.

Class V.—Metals.

11. Arsenic. 27. Gold.

13. Titanium. 29. Iridium.

Dana, in his useful 'Manual of Mineralogy,' adopts the following classification:

Class I.—Gases; consisting of or containing Nitrogen or Hydrogen.

Class II.—Water.

Class III.—Carbon, and Compounds of Carbon.

Class IV.—Sulphur.

Class V.—Haloid Minerals: Compounds of the Alkalies and Earths with the Soluble Acids, or of their Metals with Chlorine or Fluorine.

Class VI.—Earth Minerals: Silica and Siliceous or Aluminous Compounds of the Alkalies and Earths.

5. Natron. 10. Alumina.

Class VII.—Metals and Metallic Ores.

We have already observed that Mineralogy includes a knowledge of the chemical composition and of the external and physical properties of minerals, and they are all divisible into two great classes of crystallised and uncrystallised. With respect to regularly crystallised minerals, we refer for an account of their forms to what is stated under Crystallography. There are some substances which do not assume regular forms, but have an imperfect crystalline structure; while those bodies which are not either crystallised or crystalline, unless they are pulverulent, are described as massive, and these are subdivided into such as possess particular forms, as botryoidal, mammillated, nodular, stalactic, reniform, globular, and amorphous, or without any particular form.

The structure of minerals is an important feature. It may be Columnar, Lamellar, or Granular. The following are explanations of the terms used in describing the different kinds of columnar structure:—

Fibrous: when the columns are minute and lie in the same direction, as gypsum and asbestos. Fibrous minerals very commonly have a silky lustre; a fibrous variety of gypsum, and one of calc-spar have this lustre very strongly, and each is often called satin-spar.

Reticular: when the fibres, or columns, cross in various directions, and produce an appearance having some resemblance to a net.

Stellated: when they radiate from a centre in all directions, and produce a star-like appearance. Stibite and gypsum are examples.

Radiated divergent: when the crystals radiate from a centre without producing stellar forms. Examples, quartz, gray antimonite.

In the Lamellar Structure the laminae or leaves may be thick, or very thin; they sometimes separate easily, and sometimes with great difficulty. When the laminae are thin and separate easily, the structure is said to be Foliated. Mica is a striking example, and the term Micaeous is often used to describe this structure. When the laminae are thick, the term Tabular is often applied; quartz and heavy spar afford examples. The laminae may be elastic, as in mica, flexible, as in talc, or graphite, or brittle, as in diaphragm. Small laminae are sometimes arranged in stellar shapes; this occurs in mica.

When the grains in the texture of a mineral are coarse, it is said to be Coarsely Granular, as in granular marble; when fine, Finely Granular, as in granular quartz; and if no grains can be detected by the eye, the structure is described as Impalpable, as in chalcedony. Granular minerals, when easily crumbled by the finger, are said to be Friable.

Massive minerals also take certain imitative shapes, not peculiar to either of these varieties of structure. The following terms are used in describing imitative forms:

Globular: when the shape is spherical or nearly so; the structure may be Columnar and Radiating, or it may be Concentric, consisting of coats like an onion. When they are attached, they are called Implanted Globules.
Reniform: kidney-shaped. In structure, they are like globular shapes.

Botryoidal: when a surface consists of a group of rounded protuberances. The prominences or globules usually consist of fibres radiating from the centre.

Mammillary: resembling the botryoidal, but consisting of larger prominences.

Pillow: like a thread.

Angular: slender like a needle.

Stalactitic: having the form of a cylinder or cone hanging from the roofs of cavities or caves. The term stalactite is usually restricted to the cylinders of carbonate of lime hanging from the roofs of caves; but other minerals are said to have a stalactitic form when resembling these in their general shape and origin. Chalcedony and brown iron-ore are often stalactitic.

Reticulated: net-like.

The lustre of a surface is said to be drusy when covered with minute crystals.

Amorphous—shapeless: having no regular structure or form, either crystalline or amorphous.

Crystals are also called Pseudomorphs. A pseudomorphous crystal is one that has a form which is foreign to the species to which the substance belongs.

Crystals sometimes undergo a change of composition from aqueous or some other agency, without losing their form; for example, a crystal of carbonate of lime changes toGypsum, still retaining the octahedral form. Cubes of pyrites are changed to red or brown iron-ore.

Again, crystals are sometimes removed entirely, and at the same time and with equal progress, another mineral is substituting its place. This is an example of the change of one mineral into another, when the laws of crystal-structure are transferred to quartz. The petrifaction of wood is of the same kind.

Again, cavities left empty by a decomposed crystal are filled by another species by infiltration, and the new mineral takes on the external form of the original mineral, as a fused metal the form of the mould into which it is cast.

Again, crystals are sometimes incrusted over by other minerals, as cubes of flour by quartz; and when the floor is afterwards dissolved away, as sometimes happens, hollow cubes of quartz are left.

The first kind of Pseudomorph are Pseudomorphs by Alteration; the second, Pseudomorphs by Infiltration; the third, Pseudomorphs by Incrustation.

Pseudomorphous crystals are distinguished by having a different structure and cleavage from that of the mineral imitated in form, and a different hardness, and usually little lustre.

A large number of minerals have been met with as pseudomorphs. The causes of such changes have operated very widely and produced important geological results.

The lustre of minerals depending on light are also arranged. They are of five kinds, and arise from the power of minerals to reflect, transmit, or emit light. They are as follows:—1. Lustre; 2. Colour; 3. Diaphanity; 4. Refraction; 5. Phosphorescence.

The lustre of minerals depends on the nature of their surfaces, which causes more or less light to be reflected. There are different degrees of intensity of lustre, and also different kinds of lustre.

The kinds of lustre are six, and are named from some familiar object or class of objects:

Metallic: the usual lustre of metals. Imperfect metallic lustre is expressed by the term Sub-Metallic.

Vitreous: the lustre of broken glass. An imperfect vitreous lustre is termed Sub-Vitreous. Both the vitreous and in-vitreous lustres are common. Quartz possesses the former in an eminent degree; calcareous spar often the latter. This lustre may be exhibited by minerals of any colour.

Resinous: lustre of the yellow resins. Opaque and zine-blende are examples.

Pearly: like pearl. Talc, native magnesium, stibnite, &c., are pearly. When combined with sub-metallic lustre, the term Metallic-Pearly is applied.

Silky: like silk; it is the result of a fibrous structure. Fibrous carbonate of lime, fibrous gypsum, and many fibrous minerals, more especially those which in other forms have a pearly lustre, are examples.

Adamantine: the lustre of the diamond. When sub-metallic, it is termed Metallic-Adamantine. Varieties of white lead-ore are examples.

The degrees of intensity are denominated as follows:—

1. Specular: the surface reflects light with great brilliancy, and gives well defined images. Elba iron-ore, tin-ore, some specimens of quartz and pyrites are examples.

Shining: when an image is produced, but not a well-defined one. Nearly all the less transparent and less refractive minerals are shining. Glistening: when there is a general reflection from the surface, but no image. Talc and copper-pyrites are examples.

Glimmering: when the reflection is very imperfect, and the light is scattered and diffused over the surface. Flat and chalcedony are examples.

A mineral is said to be Dull when there is a total absence of lustre, as chalk.

In distinguishing minerals, both the external colour and the contiguous place that has been rubbed or scratched, are observed. The latter is called the streak, and the powd er abraded, the Streak-Powder.

The colours are either metallic or non-metallic.

The Metallic are natural and of some familiar metal, as copper-red, bronze-yellow, brass-yellow, gold-yellow, steel-grey, lead-grey, iron-grey.

The Non-Metallic used in characterising minerals, are various shades of white, gray, black, blue, green, yellow, red, &c.

There are thus snow-white, redish-white, greenish-white, milk-white, yellowish-white; bluish-grey, smoke-grey, green-grey, pearl-grey, ash-grey; velvet-black, greenish-black, bluish-black, amethyst-blue, violet-blue, sky-blue, indigo-blue, emerald-blue, turquoise, blue-green, blackish-grey, pistachio-grey (yellowish); sulphur-yellow, straw-yellow, wax-yellow, ochre-yellow, honey-yellow, orange-yellow; scarlet-red, blood-red, flesh-red, brick-red, hyacinth-red, rose-red, cherry-red; hair-brown, reddishbrown, chestnut-brown, yellowish-brown, pinchbeck-brown, wood-brown.

The expression a Play of Colours is used when several prismatic colours appear in rapid succession on turning the mineral. The diamond is a striking example; also precious opal.

Change of Colours: when the colours change slowly or turning in different positions, as in labradorite.

Opalescence: when there is a milky or pearly reflection from the interior of a specimen, as in some opals, and in cat's eye.

Iridescence: when prismatic colours are seen within a crystal; it is the effect of fracture, and is common in quartz.

Tarnish: when the surface-colours differ from the interior; it is the result of exposure. The tarnish is described as frieze, when it has the hues of the rainbow.

Polychoiroism: the property belonging to some prismatic crystals of presenting a different colour in different directions. The term Dichroism has been generally used, and implies different colours in two directions, as in the mineral lollite, which has been named dichroite because of the different colours presented by the bases and sides of the prism. Mica is another example of the same. The more general term has been introduced, because a different shade of colour has been observed in more than two different directions.

These different colours are observed only in crystals with unequal axes. The colours are the same in the direction of equal axes, and often unlike in the direction of unequal axes.

This is the general principle at the basis of polyichroism.

Diaphanity: the property which many objects possess of transmitting light; or in other words, of permitting more or less light to pass through them. This property is often called transparency, but it is properly one of the degrees of diaphanity. The following terms are used to express the different degrees of this property:

Translucent: a mineral is said to be translucent when the outlines of objects, viewed through it, are distinct. Glass and crystals of quartz are examples.

Sub-Translucent, or Semi-Transparent: when objects are seen, but their outlines are indistinct.

Amphible: light is transmitted, but objects are not seen. Leaf-sugar is a good example; also Carrara marble.

Sub-Translucent: when merely the edges transmit light faintly. When no light is transmitted, the mineral is described as opaque.
MIN 415 MIN

Those minerals whose faces emit light exhibit two sets of phenomena, Refraction and Polarisation. The index of refraction has been obtained for many minerals, of which the following are a few:

- Air: 1.000 Calc-Spar: 1.554
- Tabusheer: 1.711 Spinel: 1.739
- In: 1.355 Sapphire: 1.794
- Cryolite: 1.349 Garnet: 1.815
- Water: 1.330 Zircon: 1.961
- Fluor-Spar: 1.434 Blende: 2.263
- Rock-Crystal: 1.523 Diamond: 2.430
- Quartz: 1.546 Chromate of Lead: 2.974

Many crystals possess the property of refracting light in two directions instead of one, and objects seen through them consequently appear double. This is called Double Refraction. It is most conveniently exhibited with a crystal of calc-spar, and was first noticed in a polished variety of this mineral from Iceland, called from the locality Iceland-Spar. On drawing a line on paper and placing the crystal over it, two lines are seen instead of one—one by ordinary refraction, the other by an extraordinary refraction. If the crystal, as it lies over the line, be turned around, when it is in one position the two lines will come together. Instead of a line make a dot on the paper, and place the crystal over the dot: the two dots seen will not come together on revolving the crystal, but will seem to revolve one around the other. The separation is greatest when the crystal is cut in every direction except that of the vertical axis, and this direction is called the Axis of Double Refraction. To view it in this direction the ends must be ground and polished. The divergence increases on passing from a view in the direction of this axis to one at right angles to it, which is the greatest. In some substances the refraction of the extraordinary ray is greater in the latter direction than that of the ordinary ray, and in others it is less. In calc-spar it is less, it diminishing from 1.5445 to 1.5538. The former is said to have a Negative Axis, the latter a Positive.

This property of double refraction belongs to such of the fundamental forms as have unequal axes; that is, to all except those of the isometric system, in which the lateral axes are equal (the dimetric and hexagonal systems) have one axis of double refraction; and those in which they are unequal (the triclinic, monoclinic and triclinic systems), have two axes of double refraction.

Both rays in the latter case of extraordinary refraction. In nitre the two axes are inclined about 5° to each other; in aragonite 18° 18'; in topaz 65°. The positions of the axes taper vary widely in different minerals.

The diamond is a peculiar mineral, that possesses, besides the ordinary property of light, termed Polarisation. Viewed by means of another doubly-refracting crystal, or crystalline plate (called from this use of it an analysing plate), the ray of light becomes alternately visible and invisible as the latter plate is revolved. If the double refraction be greatly increased, the two rays are seen of the same substance, and when viewed in the manner stated, rings of prismatic colours are developed, and on revolving the analysing plate the coloured rings and intervening dark rings successively change places.

Several minerals give out light either by friction or when gently heated. This property of emitting light is called Phosphorescence.

Two pieces of white sugar struck against one another give out a light which may be taken in a dark place. The same effect is obtained on striking together fragments of quartz, and even the passing of a feather rapidly over some specimens of zinc-blende is sufficient to elicit light.

Fluor-spar is the most convenient mineral for showing Phosphorescence by Heat. On powdering it, and throwing it on a shoed heated nearly to redness, the whole takes on a bright glow. In some varieties the light is emerald-green; in others purple, rose, or orange. A massive flour from Huntington, Connecticut, shows beautifully the emerald-green fluorescence when viewed in the dark.

Some kinds of white marble, treated in the same way, give out a bright yellow light. After being heated for a while the mineral loses its phosphorescence; but a slight jar will cause it again.

Some minerals become electrified on being rubbed, so that they will attract cotton and other light substances: and when electrified some exhibit positive and others negative electricity when brought near a delicately suspended magnetic needle. The diamond, whether polished or not, always exhibits positive electricity, while other gems become negatively electrified in the rough state, and positive only in the polished state. First one of a feather is sufficient to excite electricity in some varieties of bende. Some minerals thus electrified retain the power of electric attraction for many hours, as tops, while others lose it in a few minutes.

Many minerals become electric when heated, and such species are said to be Pyro-Electric.

If a prism of tourmaline, after being heated, be placed on a delicate frame, which turns on a pivot like a magnetic needle, on bringing the needle near it, or under proximity with the prism, it will be attracted, the other repelled, thus indicating the polarity alluded to. Several other minerals exhibit electrical phenomena, especially borosrite and tops, which, like tourmaline, are bimetallic in their modifications.

Magnesium is exhibited more especially in the ores of iron. The loadstone, as the magnetic oxide of iron is called, is common where the ores of iron are found. When mounted like a horse-shoe magnet, a good loadstone will lift a weight of many pounds. This is the only mineral that has decided magnetic attraction; but several crystals containing iron are attracted by the magnet, or, when brought near a magnetic needle, will cause it to vibrate; and moreover, the metals nickel, cobalt, manganese, palladium, platinum, and osmium, have been found to attract magnets.

Minerals vary in their specific gravity. This must be ascertained for other substance. [Specifie Gravitt.] The Hardness of minerals differs much, and is the point first attended to by the mineralogist. In order to ascertain the hardness of a mineral it is only necessary to draw a file across the specimen, or to make trials of scratching one with another. As standards of comparison, the following minerals have been selected, increasing gradually in hardness from the talc, which is very soft and easily scratched with a knife, to the diamond which nothing will cut; this table is called the Scale of Hardness:

1. Talc, common foliated variety.
2. Rock-Salt,
3. Calc-Spar,
4. Fluor-Spar, crystallised variety.
5. Apatite, transparent crystal.
6. Felspar, cleavable variety.
7. Quartz, transparent variety.
8. Topaz, transparent crystal.
9. Sapphire, cleavable variety.
10. Diamond.

If on drawing a file across a mineral it is impressed as easily as felspar, which is said to be 1; as easily as talc, which is said to be 4; if as easily as felspar, the hardness is said to be 6; if more easily than felspar, but with more difficulty than apatite, its hardness is described as 5 or 5.5.

The file should be run across the mineral three or four times, and each time it should be taken to make the trial on angles equally blunt, and on parts of the specimen not altered by exposure. Trials should also be made by scratching the specimen under examination with the minerals in the above scale, as sometimes, owing to a loose aggregation of particles, the file wears down the specimen rapidly, although the particles are very hard.

Minerals differ in their state of aggregation. Solid minerals may be—

Brittle: when parts of the mineral separate in powder on attempting to cut it.

Sectic: when thin pieces may be cut off with a knife, but the mineral pulverises under a hammer.

Malleable: when slices may be cut off with a knife, and the mineral pulverses under a hammer.

Flexible: when the mineral will bend, and remain bent after the bending force is removed, as talc.

Elastic: when after being bent it will spring back to its original position, as calc-spar.

A liquid is said to be Viscous when on pouring it the drops lengthen and appearropy, as petroleum.

When a mineral is broken its cut surface presents different aspects. The following are the several kinds of fracture in minerals—

Conchoidal: when the mineral breaks with a curved or concave and convex surface of fracture. Flint is a good example.
Even: when the surface of fracture is nearly or quite flat. Uneven: when the surface of fracture is rough with numerous small elevations and depressions.

But when the elevations are sharp or jagged, as in broken iron.

Soluble minerals may have taste: the kinds are—
Astringent: of taste of vitriol.
Sweetish-astringent: the taste of alum.
Sour: taste of sulphuric acid.
Bitter: taste of Epsom salts.
Alkaline: taste of soda.
Cooking: taste of salt petre.

When obtained from the rolling tributaries of Minnesota, with the waters of Lake Superior, and other waters having a rolling course, it is obtained by friction and more distinctly by means of the blow-pipe from several arsenical ores.

Horse-Radish odour: the odour of decaying horse-radish. It is the odour of burning selenium, and is strongly perceived when ores of this metal are heated before the blow-pipe.

Phosphorescent oddour: odour of burning sulphur. Friction will elicit an odour, and have it from many sulphurites.

Feld: the odour of rotten eggs or sulphuretted hydrogen. It is elicited by friction from some varieties of quartz and limestone.

Argillaceous, the odour of moistened clay. It is given off by loosening and shaking the allied minerals when breathed upon. Others, as pyrraloglise, afford it when heated.

Without submitting the mineral to a regular analysis, advantage is often taken of the effects of heat by means of the blow-pipe, with or without the aid of certain fluxes, as soda, phosphoric salt, &c.; and the result is stated to be either fusible, or with the assistance of different fluxes, and the nature of the resulting compound is described; sometimes it is a colourless glass, at other times coloured, translucent, &c. MINNESOTA, a Territory of the United States of North America, lies between 43° 30' and 49° 22' N. lat., 90° 0' and 108° 30' W. long. It is bounded E. by the State of Wisconsin, N. by British North America, W. by the Territory of Nebraska, and S. by the State of Iowa. The area is 141,539 square miles. The population in 1856 was estimated at 160,000.

The surface of this Territory has generally the character of a rolling tableland; but there are considerable exceptions. Towards the eastern side it runs into a ridge of lofty hills, which traverses a large portion of it in a north-east and south-west direction. From a short distance above the Falls of St. Anthony, on the Mississippi, there extends southward a vast forest region for 120 miles, with a breadth ranging from 15 to 40 miles. The northern and north-eastern portion of the Territory is sometimes termed the 'region of lakes,' from the great number of lakes of various sizes which lie along the upper course of the Mississippi and its tributaries; and for some distance below this region the Mississippi traverses a swampy country.

The Territory is in every part abundantly watered. The Mississippi, lying within its boundaries in Lake Itasca; and belong wholly to it down to the confluence of the St. Croix, after which, to the southern boundary of the territory, it belongs equally to Minnesota and Wisconsin. This part of its course is described under Mississippi River. The principal tributaries which join it in this territory are the St. Croix, which separates Minnesota from Wisconsin, and the Minnesota, a large and broad stream, which rises near the centre of the Territory, flows through Big Stone Lake, and then flows generally south-west, bounding its windings of some 800 miles, first south-east, then south, and finally north-east, falls into the Mississippi at Fort Snelling. The Mississippi is navigable in Minnesota by steam-boats during seven months of the year; the other five months it is, with its tributaries, closed by ice. The Missouri, with its tributary, the White Earth River, forms the western boundary of Minnesota; it is navigable by steam-boats throughout Minnesota. It is joined by several small feeders, but by none of any consequence in this Territory. The Red River, which flows northward to Winnipeg Lake in British America, has its source in, and belongs for a considerable distance to Minnesota, and has numerous tributaries in this part of its course. The Big Sioux and several other rivers have also their upper courses in this Territory. The Mississippi, Minnesota, and St. Croix rivers, with Lake Superior, afford great commercial facilities: while the numerous smaller streams and lakes afford like facilities for agricultural and manufacturing operations. The principal lakes are the Itasca, Cass, Red, Leech, Devil, Oussulait, Big Stone, and Pepin. Besides these, there are 3,500 others.

As regards its geological character, the larger half of the country, including the centre and north-eastern portions, appears to belong to the igneous and metamorphic formations. In the northern and southern portions are considerable tracts of Lower Silurian rocks. Extending from the central eastward to Lake Superior is a narrow band of New Red Sandstone, with dykes of copper trap. The Missouri though its whole course in Minnesota appears to flow through erratic rocks, which are bordered on the east by tertiary formations. Copper- and lead-ores are said to have been found.

The climate, though severe, is not subject to rapid or extreme variations. The winters are in general rather mild, and the dryness of the air during winter, the coldest weather is endurable. A great quantity of snow falls in the winter, but generally there is not much moisture. The soil over a country so vast in extent, and having such different lithological features, is generally fertile; but it is found to be remarkably fertile, and the mould is of unusual depth. Most of the cereals appear to flourish: maize, oats, and wheat are the crops most cultivated, but rye, barley, and buckwheat are also grown. Potatoes, peas, and beans are raised to some extent. The land is well adapted for raising stock. There are at present no manufactures in the Territory. The chief occupation is the cutting and preparing of pine lumber, much of which is returned to home consumption, but the larger portion is sent to St. Louis.

At the census of 1850 Minnesota was divided into nine counties. The political capital is St. Paul, the only place which can as yet fairly rank as a town; but Pembina on the right bank of the Red River, having the first appearance of the territory—Fort Snelling, at the confluence of the Mississippi with the Mississippi—and Stillwater, on the west side of St. Croix Lake, are places of growing local importance.

St. Paul, the capital, occupies a commanding position on the left bank of the Mississippi, 15 miles below the Falls of St. Anthony, in 44° 52' N. lat., 93° 4' W. long. The first trading house was built here in 1842, it having previously been the winter station of the canoe traders of the St. Marys. It now contains a state-house 139 feet long, a court-house, jail, nine churches, schools, numerous hotels, stores, an inns, foundry, agricultural implement factories, flour-mills, &c. The streets are traversed by coaches and omnibuses; and whilst the river is free from ice, steam-vessels arrive and sail daily, although the vicinity of the town is still a wilderness. In 1850 St. Paul had 1135 inhabitants; in the spring of 1853 it is said to have had above 2000.

Minnesota has a legislature consisting of a 'Council and House of Representatives.' By the constitution, as framed by the territorial legislature, citizenship is not limited to whites, but extended to all persons of a mixture of white and Indian blood who shall have adopted the habits and customs of civilized men. Minnesota was erected into a Territory by Act of Congress in March 1849; that portion of it west of the Mississippi having previously formed a part of the Territory of Iowa, and that part east of the Mississippi having belonged to the Territory of Wisconsin. On 29th February, 1853, this Act was passed by Congress, authorising Minnesota to form a State government. This Act makes an alteration in the area of Minnesota, and consequently in the population. The Convention for forming the State was held at St. Paul in 1856; but the particulars have not yet (April 1, 1868), reached us.

MIRIAMICHI. [New Brunswick.]

MIRBEL, BRISEAU-C., a French naturalist, more especially distinguished for his knowledge of botany. He was born on the 27th of March 1776. He was appointed professor of botany in Paris in 1801, and one of his earliest published works was the introduction to his course. The subject was the influence of the study of natural history on the civilisation of man. He was associated with others in the production of the volumes on the general and special history of plants, in the series of works in continuation to the Systema Naturae. In this work he extended to eighteen volumes, the first, second, fourth, fifth, and sixth, were written by Mirbel. In 1802 he published his treatise 'On Vegetable Physiology.' He was also associated with Leopold Link, physician, botanist, and botanic historian, of the History of Plants, which was published in 1803. He subsequently, in answer to views put forth by Link, wrote an 'Exposition of the Theory of Vegetable Organization,' and also a defence of this work in 1808. In 1813 he published his 'Elements of Vegetable Physiology and Botany.' This work was published in three volumes, and was an admirable exposition of the state of vegetable physiology at the time it was published, and contained the result of numerous observations on the structure, functions, and development of plants. In 1835 he published a paper on the bark of dicotyledonous trees, in which he gave an admirable account of the structure of the bark in exogenous plants. After this he published a celebrated paper on the 'Anatomy of the Cell, and its Filaments,' in which he not only described the general structure of the plant, but the history of the development of its embryo. In his general theoretical views and numerous exact observations, Mirbel exercised a great influence on the progress of the science of botany during the first half of the 19th century. He died September 12, 1854.

MITCHELL, SIR THOMAS LIVINGSTONE, Knt., was born in 1792, at the residence of his father, John Mitchell, Esq., of Craigend, in Stirlingshire, Scotland. The name of Livingstone is thus associated with the history of the kingdom, as his father married the heiress of the line of Livingstone, Esq., of Haining, lord to Viscount Kilsyth, who was attained in 1716. Thomas Livingstone Mitchell entered the British army in Portugal in 1808, and served on the staff till the termination of the Peninsular War, when he had attained the rank of major. In the course of this service he had distinguished himself so much as to attract the attention of the late Sir George Murray, upon whose recommendation he was sent to the Cape of Good Hope as deputy surveyor-general of New South Wales under Mr. Oxley, whom he succeeded as surveyor-general—an office which he retained till his death. Besides performing the ordinary duties of this important situation, he conducted four expeditions into the interior, and was one of the most successful of the explorers of the Australian continent. Three of these expeditions were performed in the years 1831-32, 1835, and 1836. The first was in search of an imaginary river on the east coast of Australia, and his party resided among the aborigines, described as having a north-west course, and entering the sea; and the result of the journey was the discovery of the Peel River and the Namoi. The second expedition was for the purpose of exploring the course of the river Darling, and was continued in the third expedition, when the Darling was traced to its junction with the river Murray. Australia Felix was also discovered, and the Gienmel was explored to its entrance into the sea. These expeditions were made with great danger from the occasional hostility of the native tribes, and from their insidious and treacherous warfare, combined with the steadiness and resolution of an experienced leader. Major Mitchell published in 1838 his account of these journeys, under the title of 'Three Expeditions into the Interior of Australia.' He published also 'Descriptions of the recently-explored Region of Australia Felix, and of the present Colony of New South Wales,' 2 vols. 8vo, London, illustrated with lithographic drawings and woodcuts. He had a short time previously published his 'Map of the Colony of New South Wales, compiled from actual Measurements with the Chain and Circumferentor, and according to a Trigonometrical Survey, in Three Sheets.' Major Mitchell came to England for the purpose of superintending these publications, and, before his return, received in 1839, the honour of knighthood from the queen, and the title of D.C.L. from the University of Oxford. He was also elected a Fellow of the Royal Society and of the Geological Society.

Sir Thomas Mitchell's fourth and last expedition was commenced in December 1845, and terminated in December 1846. His account of it was published in 1848, under the title of a 'Journal of an Expedition into the Interior of South Australia, to the Barrier of South Australia, and Gulf of Carpentaria, by Lieut.-Colonel Sir T. L. Mitchell,' 8vo, illustrated with lithographic engravings and maps. This expedition did not reach the Gulf of Carpentaria, having been compelled to return in consequence of the loss of the cattle and horses from drought and want of pasture; but advanced as far as 21°30' S. lat. Sir Thomas Mitchell himself was the first to discover the important river which he named the Victoria, and saw it taking a north-west course, in a direction near to the bar of the Gulf of Carpentaria. Mr. Kennedy, however, Sir T. Mitchell next sent out the largest party of all his journeys in 1847, found that the river makes a great bend to the south-west, and he traced its course in that direction as far as 26°14' S. lat. The channels were in many places under water, and he was compelled to return from want of water and pasture for his horses. In 1850 Sir Thomas Mitchell published an admirable manual of geography for the schools of New South Wales, entitled 'Australian Geography, with the Shores of the Pacific and those of the Indian Ocean, descriptive of the Colonies and Settlements of South America.' He published in Sydney, in 1853 he again visited England. Having invented a new propeller for steam-vessels on the principle of the curious instrument used by the natives of Australia, he had the plan built and described the instrument which excited much interest. It was published under the title of 'The Steam-Propeller, History, and Description of the Boomerang Propeller, a Lecture delivered at the United Service Institution,' 8vo, London.

Sir Thomas Mitchell was advanced to the rank of colonel in 1854. He died October 9, 1855, at his residence in Sydney, and his remains received the honour of a public funeral.

MITCHELSTOWN, county of Cork, Ireland, a market- and post-town, and the seat of a Poor-Law Union, is pleasantly situated near the river Foss, on a small tributary, in 56°17' N. lat., 8°17' W. long., 30 miles N.N.E. from Cork, 129 miles S.W. by S. from Dublin. The population in 1851 was 3091. Mitchelstown Poor-Law Union comprises the parishes of Mitchelstown, Youghal, and 16 electoral divisions. The population of Mitchelstown in 1831, was 27,269. The town consists of an extensive square, containing some well-built houses, and of two principal streets with several smaller streets intersecting these at right angles. It contains the parish church—a handsome plain structure with a square tower—and a National school, and a town library. There are also a courthouse, fever hospital, dispensary, bridewell, and Union workhouse. Mitchelstown College, a group of neat buildings with a chapel attached, was founded by the Earl of Kingston for the support of 12 males and 16 females of his decayed Protestant tenantry. Each receives 40l. a year, besides a house and garden. On one side of the square is the gateway to the extensive demesne of Mitchelstown, the seat of the Earl of Kingston, which embraces with its towers and battlements forms a striking object. It was erected in 1833, and is the largest and finest of the modern castles in Ireland. Petty sessions are held monthly. Fairs are held January 10, March 25, May 23, July 30, November 19, and December 9.

Mitchelstown and Kigstown caves are two series of beautiful stalactite caverns, under small limestone hills about 8 miles from Mitchelstown on the Dublin road. One series, discovered in 1835, is 870 feet in extreme length by 572 feet in breadth.

MITFORD, MARY RUSSELL, one of the most delightful of our female authors, was born on the 16th of December 1786, at Alresford, Hampshire. Her father was a physician, and a man possessed of a fine mind, a love of unblushing and somewhat eccentric habits, and consequently unsuccessful alike in his professional pursuits and in his pecunary affairs. By his general want of management and inju-
dicious speculations he wasted his wife's property as well as his life and mind, with a characteristic, present mood—when his own fortunes were at the lowest ebb—to his daughter on her tenth birthday, of a ticket in the Dihlum Lottery, turned up a prize of 20,000l., that too was as thoroughly, though somewhat more slowly, dissipated as his previous wealth had been. Yet he was a man of kindliness, cheerful, and of sanguine temper, and Mary Mitford, his only child, without a murmur dedicated her life to the promotion of his comfort and happiness, and almost before arriving at womanhood devoted herself to literature as a means of eking out his diminished income.

At ten years of age she was sent to a boarding-school at Chelsea; and in addition placed under the special guidance of a governess, who, as Miss Mitford mentions in the introduction to her dramatic works, was not only herself added to the household, but also the means of making her pupils write verses also; and among her pupils she at different times numbered, besides Miss Mitford, Miss Landon (L. E. L.), Fanny Kemble, and Lady Caroline Lamb. Miss Kemble took the poetic fit strongly; and before she was twenty she had published three volumes of poetry, one of which was a romance in verse after the manner of Sir Walter Scott. They were not of much worth, but they met with rougher treatment at the hands of the "Quarterly," than their juvenile form deserved. But the latter, who had her disheartened, and she profited by the somewhat rough lesson.

Another volume of verse—"Wallington Hill; a Poem," was published in 1812. She had by this time deliberately adopted her father's pen-name, and was busy in writing short tales and sketches for the English Magazine. A number of these, collected and published, with confidence by those exercises, when the early celebrity, probably of the "Sketch-Book of Geoffrey Crayon," turned her thoughts to the writing of some descriptive sketches of English rural life. She went to the borders of Berkshire and Hampshire—Three Mile Cross, near Reading—had long been her residence; every lane and field, and almost every nook and corner of it, every house and cottage, and almost every person in them, was familiar to her; and so it was natural that faithful reproductions of country scenery and country manners as they existed in that small southern village would not be unwelcome to the world of readers.

But she met in the first instance with serious discouragement. Thomas Campbell was then editor of the "New Monthly Magazine," and the earlier essays of what ultimately formed "Our Village" were offered to him, but peremptorily rejected. They were beneath the dignity of his magazine. A subscription-list was accordingly opened, and twenty-five names were entered. "Lady's Magazine." There their freshness, genuineness, and faithfulness were recognised, and Miss Mitford, nothing loth, was called upon to publish them in a collected form. By the general public "Our Village" was warmly welcomed, and each successive volume of it found many imitators too, but hitherto no rivals. She wrote in the "Preface" when they were first collected:—"Her descriptions have always been written on the spot and at the moment, and in nearly every instance with the closest and most resolute fidelity to the place and the people. If she be accused of having given a brighter aspect to her villagers than is usually met with in books, she cannot help it, and would not if she could. She has painted, as they appeared to her, their little faults, and many virtues, as well as the intense and thankful conviction, that in every condition of life goodness and happiness may be found by those who seek them, and never more rarely than in the fresh air, the shade, and the sunshine of nature." This is a fair account of them, and they fairly represent, moreover, the gentle and healthful spirit of their authorship. "Our Village" is in all respects a work that more than any other represents in literature that phase of English taste and feeling, which is so characteristic of our own hest water-colour landscapes and scenes of country life, and of the pure air, and sunshine of England. "Our Village," altogether extended in its original collected form to five volumes, or series, the last of which was published in 1838. Of some of the sketches in the last volume Miss Mitford writes: "They are not a little want of the primal freshness, and in them, and in some of her later essays, there is too much yielding to the besetting sin of those who depict character—the tendency to exaggeration and caricature. "Belford Regis; or Sketches of a Country Town," in which the neighboring town of Reading, instead of the pretty country hamlet, supplied the material, was her most important subsequent work in a similar style. Her later sketches and essays furnished the great part of her two periodicals have not, we believe, been collected. Among her other works may be mentioned her "Stories of Country Life." She also for some years edited Fiden's "Tableaux," and three volumes of "Stories of American Life by American Authors." whilst at the Chelsea school Miss Mitford's dramatic tastes had been as carefully nurtured as her poetic tastes. The consequence was that in early life her most ardent aspirations, either as an author or actress, were directed towards the stage. She was the author of a number of plays of various kinds. Four of these were works of considerable importance. The first, "Julian," was performed in 1823, with Macready for the hero, and met with decided success. The "Fascinat" appeared with equal applause, but the "Kabouter," which was given in 1826, "Charles the First" was not so fortunate as its predecessors; Colman, then licensor of plays, having refused to sanction its performance on the ground of the impurity and danger of permitting the trial of an English king to be represented on the stage. Driven from the legitimate houses, Charles I. was at length brought out at a minor theatre, the Cobourg, and it has not apparently been repeated elsewhere. Besides these an essay, "Sakal and Kalasrade," written by her, was produced at the Lyceum, but was afterwards withdrawn. The female appearances were in an edition of her "Dramatic Works" (3 vols. 8vo, 1854), which, besides the pieces above named, included a tragedy—printed for the first time—"Otto of Wittenbach," "Innis da Caul," and others. But the "Dramatic Works" were, as she wisely withdrew a melodrama, "Gaston de Blondeville," and several "Dramatic Scenes." In looking at Miss Mitford's works, it should be borne in mind that they are written in a vein of refined fancy, full of happy images, and surrounded by pleasant circumstances, they were often related under the pressure of pensive discomfort and during much ill-health. As long as her father lived her attention to him was more mind than her success in the theatre, and shortly after his death it gave way entirely. Yet she lived and laboured on in her pretty Berkshire cottage, beloved by every friend, and cheered often by finding that her books had made her friends immortal. About three years before her death she was the accidental overturning of her pony-chaise, and thenceforth she was pretty much confined to her home; but through her prolonged and hopeless suffering, she retained her wonted cheerfulness, and even her old industry was continued. Beside her final deviation, in which her fame is chiefly founded—"Our Village"—for a new edition, which appeared in 1853, she compiled a sort of literary patch-work, "Recollections of My Literary Life; or Books, Places, and People," which is in fact a sort of general exhibition of her life. She had, she fancied, most influenced her mental career, with a somewhat large addition of extracts from her favorite authors. She also prepared the collected edition of her "Dramatic Works," already noticed—to which were prefixed various autobiographical introductions; and in 1854 she published "Atherton; a novel," in 3 vols. She died at her residence, Swallowfield Cottage, near Reading, on the 10th of January 1855. [4.]“
which brought him little profit or fame. He was also a member of 'The Musselburgh Forum,' a debating society, in which he favourably distinguished himself. In 1817 he entered into business as a partner, in his native town, with Dr. Brown, who had an extensive practice, and Dr. Moir worked hard at his professional duties, but, when the toils of the day were ended, he employed a great part of the night in his literary pursuits. He was at this time a frequent contributor to 'Blackwood's Magazine.'

When 'Blackwood's Magazine' was started, he became a still more constant contributor to its pages. He wrote for it both prose and poetry, both comic and serious. Among his comic effusions were 'The Eve of St. Mark,' 'The New Philosopher,' and 'Some Observations on the Art of Politicking,' which attracted the attention of the Emperor Napoleon I., and secured for him the post of auditor of the Council of State. These essays, as may be supposed, were of a highly absolutist cast, and though their author continued to hold the same position in the absolutist government, he eventually retired to Edinburgh, where he was elected a member of the Legislative Assembly. He took little or no part in its proceedings. The family of Conant Moly was of that rank which is known as the 'nobility of the robe,' and his ancestors were of gentle blood as long ago as the days of Henry IV. Talents and administrative capacity seem to have been hereditary in the family, as well as the love of legal order, monarchy, and constitutional government. Conant Moly was almost the last remaining link between his countrymen of the old and of the new régime, combining the high-bred tone and monarchical principles of the former with a proportion of the liberal principles which are the distinctive mark of the latter class. But while Conant Moly accepted each successive change in the governing system of his native country, he never could be said to have swerved in principle from the opinions which he had originally professed. At the close of his long career, under various successive changes of government, he retired in 1852, with relations with the ancient dynasty, and departed life as he entered it, a devoted to the old monarch. In his theological opinions he inclined to the Ultramontane party, and from his high character, great abilities, and illustrious position, he was one of the strongest supporters of the Roman Catholic Church in France. His memoirs, which naturally include reminiscences of all the great men and notables of France during the first half of the 19th century, were announced as in preparation, but have not yet (April 1855) been published. He died suddenly at his family seat at Château du Buisson, November 23rd 1855.

MOLE'SWORTH, RIGHT HON. SIR WILLIAM, eighth Baronet of that name, was born in 1810. He was the lineal representative of an old Cornish family of landed possessions, originally of Irish extract. Sir William was governor of Jamaica in the reign of Charles II. Sir William's father died in 1823. It is uncertain at what school Sir William Molesworth was first educated, but it is certain that having spent some time at Cambridge, he was sent to the University of Edinburgh, and there studied metaphysics, metaphysical science, and by an Italian refugee, and afterwards passed to a German university. In this latter soil his mind took deep root; he acquired the German language, and followed after the bent of his own vigorous and original genius. He was educated in the study of general and classical knowledge, he concentrated his powers in Germany upon the study of philology and history. His mind however revolted against the mysticism of the German school, and as soon as he was released from collegiate study he made the usual tour of Europe. On his return to England in 1831 he was still in his minority. His first public appearance in this country was at a meeting convened in his native county in that year for the purpose of supporting the Reform Bill, and has continued to the present occasion gave considerable promise of future eminence. He was little more than of age when he was returned to parliament unopposed in December 1832, for East Cornwall, by which constituency he was re-elected in December 1834, but withdrew from the contest in July 1837, when he returned for Leeds. At the dissolution of 1841, being convinced that his chance of success at Leeds was hopeless, he declined a contest, and remained out of parliament for four years.

During this period the government, in the name of the people, and social economy, gave him a sounder political education, and accumulated capital for his future senatorial life. In 1850, however, on the death of Mr. Wood, he offered himself as a candidate for the representation of Southwark, and though strenuously opposed by a strong member of the Whig party, was elected. He was sent to Mollinsworth College, he was successful, and he continued to represent the same constituency to his death. In January 1853 he accepted the office of First Commissioner of Public Works on the formation of Lord Abercorn's land admi-
MOLLUSCA. It is but bears posterior, larger.

was re-elected without opposition; and again on his subsequent translation to the Colonial Office.

As a 'Commons' debater Sir William Moleworth was not of first-rate eminence. His speeches in parliament were few, but always of very high value. He was a Cæsar of tone and principle, generally popular. Those on the colonies, delivered in 1838; in 1840 on the state of the nation and the condition of the people; on transportation, in 1837-38; and on many important questions, were of great merit and immense practical utility. They were carefully prepared beforehand, and were the results of reading, labour, and reflection.

In July 1855 Sir William Moleworth found a sphere far more congenial to his tastes, and more congenial to his administrative ability, on being appointed to the secretariestry of the colonies, but he held that office only for the brief space of four months, when his career of public usefulness was cut short by death, which occurred on the 22nd of October 1855. The colonial and domestic press was all but unanimous in expressing their satisfaction at his appointment; it was not forgotten that he had taken the deepest interest in the affairs of Canada and Australia, and had studied the problem and mastered the theory of colonisation to a greater extent than perhaps any contemporary. Neither was it forgotten that he was the first person who, in this country, succeeded in calling public attention to the manifold abuses connected with the transporation of criminals, though eighteen years had elapsed since the Select committee, on which he was chosen, brought to light all the horrors of our penal system.

In the words of a writer in the 'Times,' 'Sir William Moleworth found our colonial empire disorganised and discreditable, but with the appointment of the Colonial Office had welded as it then was to a system of ignorant and impertinent interference. He first aroused the attention of parliament to the importance of our remote dependencies, and explained with incomparable clearness and force the principles of colonial self-government. With untiring diligence, and great constructive power he prepared draught constitutions, and investigated the relations between the imperial government and its dependencies. Starting from a small minority, he brought the public and parliament over to his side, till principles once considered as paradoxes came to be regarded as axioms. By such means he fairly won the position of Secretary of State for the Colonies; but he did not live to enjoy the prize which he had grasped. Before we had time to hear of the satisfaction with which his appointment was sure to be hailed by our remote dependencies, the sceptre was snatched from his hand by death, and the post became again vacant. In the full vigour of life and intellect, in his possession of what must have been to him the highest and most interesting office, in the possession of the confidence of his sovereign and the esteem of his fellow-subjects, he was taken away suddenly and prematurely, yet not so soon as to deprive his friends of the consolation of thinking that he had filled the place he durably occupied which will link his name with the destinies of every British colonisation—the plantations on the face of the earth. The best monument that could be raised to him would be a complete collection of his parliamentary speeches; the noblest epithet that could be inscribed on his tomb would be the title of the 'Liberator and Regenerator of the Colonial Empire of Great Britain.'

Though he had not avowedly appeared before the public as an author, Sir William Moleworth was favourably known in the world of letters and science. Having purchased the 'Westminster Review,' he for some years conducted it either alone or in conjunction with his friend, Mr. John Stuart Mill, the eminent political economist, and during that time he was a not unfrequent contributor to its pages; he likewise wrote at different times many articles in other periodicals and newspapers. He also edited and published at his own expense a complete edition of the English works of the philosopher Hobbes, in 16 volumes. [Hobbes, Thomas.] In addition to these, Sir William Moleworth had obtained some reputation as a botanist; he was appointed a member of the Linnean Society, and in 1838 was elected one of the large range of subject. In private life few men have been more highly esteemed.

MOLLUSCA. Referring to the articles CONCHIFERA, GASTROPODS, and BIVALVES, and Malacology, fora complete account to the zoological arrangement and subdivision of the various families of the Mollusca, we shall in the present article consider the animals which constitute this great group in a purely anatomical and morphological point of view; that is, we shall endeavour to show—firstly, what Common Plan or Archetype is discoverable among the varieties of Mollusca forms; secondly, in what way the Common Plan is more specially modified in the leading sub-types of this great division: of the animal kingdom; thirdly, the various modifications of the same, into which the Archetypes have been—and fourthly, the development of the Mollusca, so far as it bears upon the idea of a Common Plan or Archetype.

1. The Common Plan or Archetype of the Mollusca.—By the Common Plan or Archetype of a group of animals we understand nothing more than a diagram, embodying all the organs and parts which are found in the group, such as rails, rods, and bent; and each of these parts is divided into its various subdivisions, so that diagrams of a work on mechanisms have to actual machines, or those of a geometrical work to actual lines and figures. We are particularly desirous to indicate the sense in which such phrases as Archetype and Common Plan are here used; as a very injurious realism—a sort of notion that an Archetype is itself an entity—appears to have made its way into more than one valuable anatomical work. It is for this reason that the term Archetype had not so high authority for its use, we should prefer the phrase 'Common Plan' least ambiguous.

There are two modes in which the Archetype or Common Plan of any group of animals may be set forth. In the first, the community of plan among the members of each group would be represented by lines being compard together, the general Common Plan would be deducible. But this analytical method (which has been carried out to a certain extent for the Mollusca by the writer in a Memoir in the 'Philosophical Transactions' for 1839), would require more space or illustration than can be devoted to it; we must, therefore, take the opposite course, and, assuming a Common Plan, trace out its modifications in the subordinate plans, and explain the laws by which operation they may be affected.

The assumed Common Plan or Archetype of the Mollusca may be represented by fig. 1. 1—

This figure is supposed to be bilaterally symmetrical, and the following parts and regions to be distinguished in it: (1) The Brain Region, or that area of the animal which at the front is situated, and which corresponds with what is commonly termed the dorsal region. The word dorsal, however, is vague, being used in different senses in various divisions of the animal kingdom, and should therefore be abandoned in philosophy. The cerebral region is, however, or at least that portion of the brain (N) is termed, not ventral, but Neural, inasmuch as it is the region in which the great centres of the nervous system are placed. The termination (a) is the anterior oval; the bud (u), the posterior, the European in it. The neural surface is that upon which the majority of Mollusca move, and with which they are supported; and it is commonly modified to subserve these purposes into a muscular expansion or disc called the Foot. Three regions again, often very distinctly divided from one another, may be distinguished in this foot:—an anterior, the Propodium (pp); a middle, the Mesopodium (mu); and a posterior, the Metapodium (wm). In addition to these, the upper part of the foot or the Portion (w) may be produced, by a sublateral enlargement on each side, just below the junction of the hemal with the neural region—the Epipodium (ep). The mass of the body between the foot proper and the abdomen, or post-abdomen, which bears the Epipodium, and whose limits cannot not very well be defined, though it would be very convenient to have a name for it, may be termed the Mesosoma (m-body); and for what is loosely called the head the same Prosoma might advantageously be adopted. On the upper part of the foot or Portion there may be profusely distributed, as organs of sense: the Eyes (which may be supported on pedicles—Ommatophores), and the Tentacles. In the neural region the integument may be peculiarly modified and raised in the form of various series of swellings, the Arrangement of the anus, and when so modified it is called a Mantle (Palium). In front of the anus again the Branchiae (t) project, as processes of the hemal region. Among the internal organs we need only point out the position of the Heart (s, 9), which lies in front of the branchial in the hemal region; and the
Nervous Ganglia (x, y, z), of which there are three principal pairs arranged around the alimentary canal, which they encircle by means of their commissures.

I. The Ideal Archetype or Common Plan of the Mollusca.
II. Modifications resulting from the development of the Post-Abdomen.
III. Modifications resulting from the development of a post-abdomen and consequent haemal flexure.

M. 

1. Modifications Resulting from the Development of a Post-Abdomen and Consequent Haemal Flexure.

The latter have the same significance to these and all the other figures, with the exception of figure 10.

Such is the Common Plan of which all Molluscs whatsoever may be regarded as modifications; the next question is, to consider the laws according to which the plans of the great sub-classes of the Mollusca may be derived from it.

2. Modifications of the Common Plan.—The structural peculiarities of all known Molluscs may be very simply accounted for by the excessive or defective relative development of certain regions in the Archetype, more particularly of one or other parts of the Haemal Region. Of this region the portion which lies in front of the anus may be conveniently termed the Abdomen, while that which lies behind it the term Post-Abdomen may be applied. Now, if it be supposed that the Abdomen grows out of proportion to the rest of the body, constituting a kind of prominence, and that the intestine passes into the outgrowth so as to form a sort of loop (fig.), it is clear that the open angle of this loop will be turned towards the Neural surface; and the intestine may be appropriately said to have a Neural flexure. On the other hand, if it be supposed that the Post-Abdomen grows out in the same way, and draws into itself a loop of the intestine, then the open angle of the loop will lie in the opposite direction, that is, it will be directed towards the Haemal surface; the intestine therefore may in this case be said to have a Haemal flexure. It will be readily understood that either Abdomen or Post-Abdomen may develop a mantle or not, and that the existence or absence of this mantle have to do with the nature of the change in question, however much it may affect the external appearance of the resulting form.

Again, the extent to which the Abdomen or Post-Abdomen is developed may have a great influence on the relative position of certain organs of the Mollusc. Thus, in the first place, the position of the anus may become greatly altered. When there is a neural flexure it will acquire a direction towards the neural surface and backwards, the final approximation to the neural surface depending on the development of the abdomen on the one hand, and that of the neural region on the other. Again, if the outgrowth of the abdomen take place, not symmetrically, but more or less on one side of the median line, the final position of the anus will be towards the opposite side and to the right or left, as the case may be.

It is even conceivable (this amount of modification indeed actually obtains in nature) that by an exceedingly one-sided development of the abdomen, the anus may be thrust round on to the haemal side. Its final position therefore must not be regarded as certainly indicative of the direction of the flexure by which it obtained this position. Where there is a neural flexure again, the direction of the anus will be normal to the neural surface; and it may thus be directed forwards; its approximation to the head, its asymmetrical position, and the amount to which it may be thrust backwards and towards the neural side, depending upon conditions of the same order.

It is not merely the anus which is affected by these changes however; the branchiae (and the heart which follows them) undergo similar transpositions, whose nature and origin it is very necessary to understand, in order to appreciate their close as organic characters. M. Milne-Edwards long ago pointed out the singular fact that, in certain Molluscs, the branchiae are in front of the heart, while in others they are behind it. The latter he termed Opisthobranchiate, the former, Prosobranchiate. It will be seen that our Archetype is Opisthobranchiate. Now, it is easy to understand that if an Abdomen were developed in front of the heart, without involving the cardiac region, the Mollusc would remain opisthobranchiate; if however it were more extensively developed, so as to involve the heart and branchiae, the former having been in front, would eventually take a position posterior to the branchiae, and the Mollusc would thus become prosobranchiate. So, with regard to the development of a Post-Abdomen; its effect on the position of the heart and branchiae may be similarly determined. An absence of the neural surface which it involved. It follows, therefore, that Opisthobranchism may co-exist with either a haemal or a neural flexure, or with none; while Prosobranchism indicates one or the other, but not both; and that these organic characters, however valuable, are secondary to and therefore of less importance than the neural and haemal flexures (that is, development of an abdomen or post-abdomen), on which they depend. Dealing with the facts furnished by adult structure alone then, there are two primary modifications of the Molluscan Archetype, which may be shortly termed the Neural and Haemal Plans. The Cephalopoda, Pteropoda, Lamellibranchiata, Brachiopoda, and Polyzoa, are the molluscs which present modifications of the Neural Plan. The Heteropoda, Gastropoda, Polyplacophora, and Aequiibranchiata, are those which present modifications of the Haemal Plan.

The Neural Plan and its Principal Modifications.—Milne-Edwards has proposed a division of the Mollusca into the Mollusca proper, and the Mollusca (Molluscoidea), including under the latter class those Polyplacophorian forms, the Polyzoa and the Aequiibranchiata. Believing that the Mollusca included all those invertebrates in which the anus, or Mollusca, we nevertheless consider the distinction drawn by the eminent French naturalist to be very important, and that it should be retained as a primary subdivision of the great Haemal and Neural Divisions. In the haemal division the limits of the Molluscoidea are the same for us, as for M.
The Polyzoa.—Conceive the abdomen of the Archetype to be greatly prolonged, the neural region with its appendages, the organ of sense and the heart remaining undeveloped; so that the anus comes into close apposition with the oral extremity, while the edges of the latter are produced into long ciliated tentacles, and the result will be a Polyzoa, which needs only the power of gellation to give rise to those composite aggregations which are so characteristic of the group.

The Polyzoic type itself presents five subordinate modifications in the five principal orders of the group:—the Cyclostomata, Ctenostomata, Cheilostomata, Hipposcoopya, and Pedicellaria.

In the first three, the body of the Polyzoa when fully expanded is completely straightened, there being no permanent fold or inversion of the integument. In the last two there is such a permanent inversion. In the Cyclostomata the horny or calcareous deposit in the integument of the abdomen forms the soft parts by an even level edge, and there is nothing which serves as a cover or operculum for the retracted Polyzoa.

In the Ctenostomata (fig. 2, 3) the margins of that portion of the abdomen which is inverted in the retracted state are produced into a toothed horny sheath, which can be retracted by special muscles, and which serves as an operculum. In the Cheilostomata (fig. 2, 1) the horny or calcareous deposit takes place in such a manner that the hardened integument of the front portion of the larval region constitutes a sort of lid, regularly articulated upon the hinder portion, and provided with proper occlusor (and perhaps levator) muscles. It should be noted that the anal aperture is directed away from this lid or operculum.

In each of the previous divisions the tentacles are arranged on a circular disc, or lophophore, of whose edges they are prolongations; but in the great majority of the Hipposcoopya (fig. 2, 3), which are all fresh-water forms, the lophophore is so produced into two arms on the anal side as to assume a horse-shoe shape. It is important to consider this in connection with the peculiar features presented by the Brachiopoda.

Thirdly, we venture to regard the peculiar genus Pedicellina (fig. 2, 4) as constituting an order by itself. Essentially a Polyzoa, it is nevertheless distinguished from all other Polyzoa by the circumstance that its tentacles are united together by a membrane into a cup, which cup is never protruded far beyond the general boundary of the body.

The Cheilostomata are remarkable for possessing two kinds of moveable appendages—Patellaria, whip-like processes, articulated to a bulb containing muscles by which they are moved; and Ancillaria or bird's-head processes (fig. 2, 6). The structure of the latter is of great interest in a morphological point of view, and demands particular attention. They consist of a larger piece, or valve (p), shaped like a bird's head, and produced into a longer or shorter process of attachment, to which a smaller valve (e), representing the bird's lower jaw, is articulated. Stalked or sessile, these ancillaria present during life an incessant snapping action, produced by the alternate contraction of two sets of muscles, which arise from the concavity of the 'skull' of the bird's head by wide fan-shaped origins, and seem to be inserted by narrow tendons into the smaller articulated valve. The one tenon (e) is inserted into the smaller valve in front of the line of articulation, and the other (a) behind it, and therefore by their alternate action they raise and depress the lesser valve upon the larger.

The Brachiopoda.—Now, if we compare the relative positions and mode of articulation of the operculum and cell of a Cheilostomatous Polyzoa, or of the shell of an avicularium, with those which obtain in the shells of the typical Brachiopoda, such as the Terebratulidae and Bithyniellidae, the resemblance will be very striking; and still more so, if in addition the arrangement of the muscles be taken into consideration. In such a Brachiopod, in fact (fig. 3), the shell is composed of two valves—one large, excavated, and produced into a canal or tube, through which a pedicle of attachment passes; while the other is smaller and more or less flattened. The two valves are articulated together by means of a socket in the smaller valve and a tooth in the larger, on each side, the intermediate space being free, just as the operculum of the Polyzoa is united with its cell, or as the lesser valve of an avicularium is articulated with the larger. So likewise the anal extremity of the Brachiopod is turned from the smaller valve. Then the arms of the Brachiopoda are essentially comparable to those of the lophophore of a Hippocrepian Polyzoa, except that their direction is different; the calcified supports to which they are fixed in many Brachiopoda, are so variable in form and so extensively absent in others, that their ex-clause can in no wise affect the homology of the parts. Again, if we leave out of consideration the pedicle muscles (which are however, in all probability, as Mr. Hancock has shown, the homologues of the retractors of the Polyzoa), the arrangement of the other muscles is precisely what we have seen to obtain in the avicularium: the adductors which pass from the larger valve to be inserted into the smaller, in front of their point of support, corresponding precisely with the occlusor muscles of the avicularium; while the cardinal muscles, which arise from the larger valve, and pass to be inserted into the cardinal process of the smaller, behind the point of support, are identical with the divaricator muscles of the avicularium.

The existence of distinct muscles for the purpose of separating the valves of the shell is characteristic of the Polyzoa and Brachiopoda, the only approximation to such an arrange-
ment at present known among the _Lamellibranchiata_ being presented by the _Pholades_.

Finally, if the great proportional size of the _Brachiopoda_ their pedunculated attachment, their thick and solid shells, and their simple forms, they brought forward as arguments against the view we take of their essentially polyzoic nature, we would remark the object of the like opposition in such features between _Botryllus_ and _Botryllus_, or _Apodium_, among the Ascidians.

Two principal modifications of the common _Brachiopoda_ plan are to be observed. In the _Terebratulidae_ and _Rhynchonellidae_, and in all probability in their extinct allies the _Spiriferidae_, _Orthisidae_, and _Productidae_, the muscles are always arranged in three sets—Adductor, Cardinal, and Peduncular. At the same time the mantle (whose homology with the produced edges of the non-retractile part of the abdomen of a Polyoon is at once appreciable), though divided into two distinct lobes in front, is continuous and entire behind, that is, towards the peduncle. A still more remarkable feature in their organisation is that, at least in _Ptilodictya_ and _Rhynchonella_, there is no anal aperture, the intestine terminating in a cecum, directed towards the middle of the large valve.

In the _Cranidea_, _Discinidae_, and _Lingulidae_ the muscles have a very different arrangement, which could only be rendered intelligible by detailed description and illustrations, as the homologies of these muscles with those of the other division are not yet determined. The lobes of the mantle again are completely separated (_Discina_, _Lingula_, _Cronia_), and the intestine opens upon one side of the body between these lobes. There are no teeth, and the articulation of one valve with the other and the modes of attachment vary remarkably; _Lingula_ having a long peduncle; _Cronia_ being attached by the surface of its lower valve; and _Discina_ having an aperture in the corresponding valve through which a portion of the adductor passes, and spreading out at its extremity into a sort of ping, acts as a pedicle.

**Neural Mollusca.**—The _Lamellibranchiata_. In all _Mollusca_ proper the neural region is developed to a much greater extent than in the _Mollusca_, and there are always three pairs of ganglia, two _Cerebral_, two _Pedal_, and two _Parieto-Splanchnic_ (or _branchial_). The special characters of the _Lamellibranchiata_, as modifications of the _Archetype_, are the following:—The _hemal_ region is well developed in its abdominal portion, but forms no prominent sac-like abdomen, into which the viscera enter in the adult condition. Its edges are produced into extensive palial lobes, which are arranged on each side of a longitudinal plane, and not above and below a horizontal one (or more properly before and behind a transverse one), as in the _Brachiopoda_. The mouth is surrounded by a fringe, representing the tentacles in the _Mollusca_ (as may be well seen in _Pecten_, fig. 4, 4) which is produced laterally into elongated ‘palps,’ but not provided with any manducatory apparatus. The intestine passing from the stomach either forms a simple loop with a second open angle directed hemalia, or this loop may be much coiled and convoluted, the intestine finally passing over the great posterior adductor and terminating between the lobes of the mantle behind it.

The foot may be more or less largely developed, but never presents any clear distinction into _pro-meso- and metapodium_, unless indeed, as we are inclined to suspect, the whole free portion of the foot of the _Lamellibranchiata_ ought to be regarded as a modified metapodium. Besides the pedal muscles, the Lamellibranchs possess one or two characteristic muscles—the adductors, which approximate the valves of the shell, and whose greater or less development seriously affects the ultimate form of the animal.

The gills do not lie little from the archetypal form and position in some Lamellibranchs, such as _Trigonia_ and _Pecten_, merely thrown downwards by the development of the mantle. In _Fucula_ (fig. 4, 3), their inner edges are united posteriorly, but they remain comparatively small, in the majority of Lamellibranchs, however, the gills are exceedingly large in proportion to the rest of the body, and consist of two double plates, which are united with the mantle and with one another, in such a manner as to divide the pallial cavity into two chambers, a _supra- _and _infra-branchial_, which communicate only by the passage between the anterior edge of the branchiae and the foot, and by the multitudinous perforations in the branchial plates themselves.

It is in the absence of external organs of sense or of any buccal masticatory apparatus, and in the peculiar arrange-
forms, the former being as much as possible elongated longitudinally, the latter attaining the extreme of concentration about a centre. At the same time there is a reduction of parts to a minimum, as shown in the absence of a second adductor, and of any foot in the adult state. The differences between these forms are, however, decidedly less than those which may be observed between the extreme forms among the Cephalopoda or Gastropoda.

The Pteropoda and Pulmonata.—The Lamellibranchs are, as we have said, curiously exceptional in preserving the general characters of the Mollusca proper, without that singular buccal apparatus which we meet with in all other members of the subdivision, whether neural or hemal, and whose peculiar nature is described below. Again, they are exceptional in the vast development and symmetrical longitudinal division of their mantle, and in the corresponding division of their pallial shell into two pieces or valves—characters we shall not meet with again in any modification of the Common Plan.

In the Pteropoda and Pulmonata the mantle is never developed into such lateral lobes, and the shell to which it gives rise never consists of two pieces, but is constituted by a single mass, which either has the form of a flat plate or presents some modification of a cone. Again, the foot (or some part of it) is always well developed, presenting no obvious distinction into regions in the Pulmonata; but in the Pteropoda often exhibiting a well-marked meso- and metapodium, and always presenting a characteristically large epipodium—an organ which in these Mollusca constitutes the so-called 'wings,' from which their name is derived.

**Fig. 5.**

There is usually a well-developed mantle in the Pteropoda and Pulmonata, and its wall acts as a branchial surface without being produced into true gills—(Hyalaea)—the sea-water in the marine Pteropoda and the air in the terrestrial and aquatic Pulmonata being inspired and expired into its cavity.

In the Pteropoda in general, the aperture of the pallial cavity and that of the anus, are situated upon the posterior surface of the body, in accordance with the neural structure of the intestine. The anal aperture however is usually thrust to one side of this surface, and, in Limacina and Spiralis, this lateral thrust has taken place to such an extent, that not only the anal aperture, but that of the mantle cavity, is thrown up completely on to the dorsal surface. This lato-dorsal, or dorsal position of the anal and respiratory apertures, is as regular in the Pulmonata as it is exceptional in the Pteropoda.

In the Pteropoda and Pulmonata some most important modifications of form are produced by the greater or less development of the mesoepistomes on the one hand and of the mantle on the other. The predominance of the latter is to be observed in such forms as Crisia, Cleodora, Hyalessa, and Helice; while the former may be seen in Pneumodermon and in Limacina. In the latter the mantle is very small, and in the former it is almost if not entirely absent; what is ordinarily considered as the mantle in this mollusc being in fact nothing more than the mesoepistomes. The like con-
shell, and in the nature of the appendages into which the edges of the foot are modified—characters which do not attain to ordinal importance in other divisions of the Molusca.

Having thus glanced at all the leading modifications of the Neural Plan, we may now turn to the Hemal Plan, commencing with its Moluscid modification constituted by the Ascidioida alone.

The Ascidioida.—As a Moluscid group, the Ascidians are characterised, in the first place, by the rudimentary condition of their whole neural region, and by the reduction of their nervous system to a single infra-esophageal ganglion. Besides these, however, their organisation presents certain characters which appear at first sight very remote from such a Common Plan as has been described, and hardly deducible from it. As Ascidians, in fact, is usually fixed by one extremity of the body, and presents at the other two apertures. One of these leads into a wide cavity, whose entrance is fringed with a circle of tentacles, and whose walls (except along the middle line anteriorly and posteriorly) are perforated by innumerable ciliated apertures, and often thrown into folds, by which their surface is greatly increased. At the bottom of this cavity—the branchial sac—a second wide aperture leads into the alimentary canal, which invariably presents a haemal flexure, and then almost always fixed by one extremity of its small ciliated apertures which have been mentioned. The single ganglion lies between the oral and cloacal apertures.

Now, in what manner is this form derivable from the Archetype? It is to be remarked, in the first place, that the pharynx, large in the Potyzoa, becomes comparatively enormous in the Ascidians; while the tentacles, which were very small in the former case, become large in the latter; in the Ascidians the haemal flexure, which in the former case was very slight, but had been developed, and that its free margin remaining small and narrow, has followed the anus to the neural side, while its cavity has extended up on each side of the pharynx to the middle line of the haemal surface of the latter, carrying with it the haemal cavity. This is seen in Cynthia, and giving rise to the atrium, imagine also that the sac thus constituted externally by the inner surface of the mantle (third tunicle), and internally by the pharynx, becomes perforated by minute apertures—and the result would be an Ascidian.

Such is the manner in which the Ascidian type is derivable from the Common Plan. Of this type the group presents three anadactyl modifications. The first is that presented by the external form as seen in Cynthia (7, 7), which in a manner represents permanently the larval state of the more perfect members of the group—swimming by means of a long rapidly-vibrating tail, like that of a tadpole. In Appendicularia there is no cloacal aperture or atrium. The mouth opens into a wide pharynx representing the branchial sac of other Ascidians; from this a gutlet leads into the stomach. The narrower intestine passes from the stomach, forwards and to the haemal surface, its cavity being also perforated by minute apertures, the duct being surrounded by any special cavity. In Appendicularia therefore it might be said to be a form in which the process of modification of the Moluscan Archetype into the Ascidian type is arrested half way.

In all other cases this process is complete, and there is a distinct cloacal aperture and atrium; but these forms again may be arranged under two great sub-types of modifications, according to the development of the branchial sac relatively to that of the meso-abdomen. In such forms as Cynthia, Botryllus, Perophora, Botryllus, the branchial sac attains so great a proportional size as to occupy the whole, or nearly the whole, length of the body, the intestine lying on one side of it; these might therefore be well denominated Ascidia Haemal Branchial Ascidioida. On the other hand, in Clavelina, Aplidium, Polycystus, Salpa, the alimentary canal lies completely behind the branchial sac, which is proportionally small, and these might therefore be termed Ascidia Intestinalia, Intestinal Ascidioida. A very complete mutual representation will be found to obtain between the members of these two groups.

Hemal Molusca.—In passing from the Hemal Moluscosa to the Hemal Molusca, we find the same new features presenting themselves as in the Neural Division, the transition being even more abrupt, from the absence of any representative of the Lamellibranchiata. In all these Molusca, in fact, there is a more or less well developed foot; a distinct head, with its organs of sense and buccal armature; and three pairs of ganglia—cerebral, pedal, and parieto-spinalchic.

The modification of the Common Plan is carried to a less extent in this than in the Neural Division, the chief varieties of its forms depending on the changes in the shape of the shell with which the majority are provided; in the greater or less development of the different regions of the foot; but most of all in the relative proportions of the mesosoma and mantle.

If we divide the Hemal Molusca into two great groups—the one consisting of the Heteropoda, Scutibranchiata, Tubulibranchiata, Pectinibranchiata, and Cephalocheiata. families, which are most intimately allied, and which are connected as a group by the fusion of their reproductive organs; and the other of the Vridibranchiata, Inferibranchiata, and Testibranchiata, families in like manner united, among other characters, by their common hermaphrodisism, then we shall find in each such group two extremes of form—the one resulting from the great development of the palpial region, the other from that of the mesosoma. In the Monoecious Division, Dentalia, Verruca, Atlanta, and the ordinary Pectinibranchiata may be regarded as examples of the former group; while in the Monocious Division the Inferibranchiata and Testibranchiata, while the mantle becomes rudimentary or absent altogether in the Monocious Dentalia, in the Monocious Phyllirose, and the Vridibranchiata in general, where the region from which the mantle is derived is that which is called the mesosoma, commonly called the mantle of Atlanta for example, but of its mesosoma, which

31
MOL 426 MOL

The foot in the Monocionous Hemal Mollusca rarely presents any special development of its different regions, except that in certain forms—namely, Aplysia and Gasteropeteros—the epipodium is as well marked as in the Pteropoda, and serves the same end in locomotion. This is well known in Gasteropeteros, and we have seen a tropical Aplysia "fly" through the water in precisely the same way as a Pteropod would do. These epipodial lobes have been frequently called mantle, although the true mantle is a most distinct and obvious structure.

In the Dioecious group the epipodium is never well developed, presenting itself at most under the form of little lobes and processes—at least it would seem probable that the neck-lappets and head-lappets of the Trochodide are rudiments of the epipodium. On the other hand, it is in this group that the propodium, mesopodium, and metapodium attain their most complete and distinct form; as in Atlanta, where the propodium constitutes the anterior flattened fin, the mesopodium the rounded sucking disc, and the metapodium extends backwards, as the tail-like lobe which carries the operculum. In Firoloides we find that the mesopodium has vanished, and the metapodium has taken the form of a mere filament, while the propodium constitutes the great swimming fin.

In the ordinary Pectinibranchia, on the other hand, the foot may not be differentiated into its subdivisions at all, the metapodium being marked only by the position of the operculum, when this exists, as in Bucephalus. In other cases, as in Oliva and Sigaretus, a deep cleft marks off a very distinct propodium from the conjoined mesopodium and metapodium; in others, as in Pteroceras, the metapodium is as specialised as in Atlanta; while again, in such forms as Natica, the three constituent parts are distinguishable—the propodium constituting the hood in front of the head; the mesopodium the creeping disc; and the metapodium the opercular lobe. (Fig. 9.—8 and 9.)

If we bring in review those modes of arrangement of the various organs of the Mollusca which constitute the Common Plan of the group and the subordinate plans of its leading subdivisions, we have next to consider the peculiarities presented by these classes themselves, or, in other words, those more striking features in which the organs of the Mollusca differ from those of the Vertebrata, Annuulose, and Radiata. The most important organs, in this point of view, are those of—I, the Alimentary; 2, the Circulatory; 3, the Respiratory; 4, the Renal; and 5, the Nervous System.

1. The Alimentary Organs, in certain Mollusca, present two kinds of apparatus which are met with in no other division of the Animal Kingdom. The first of these is that peculiar mandibular apparatus usually called the 'tongue' which is possessed by all the Mollusca proper, except the Lamellibranchiata; and for the first description of whose true structure and mode of action we are, believe, indebted to Mr. Thompson (see article 'Tongue', in the 'Cyclopedia of Anatomy and Physiology'), although the organ itself had been more or less an object of attention ever since the time of Cuvier.

Foot of Pectinibranchia.—1, Trocha; 2, 3, Natica.

The tongue is essentially composed of a cartilaginous mass, with a pulpy-shaped upper and anterior surface, which projects from the bottom of the oral cavity. An elastic plate plays over the lappet, and is attached at each end to muscles which arise from the upper and lower surfaces of the cartilaginous mass. Along the middle line of this elastic plate successive transverse series of strong recurred teeth are set—new ones being continually formed behind as the old are worn away—in a sort of persistent dental sac.

When the tongue is brought into play it is protruded by appropriate muscles from the cavity of the mouth, and its extremity is firmly applied against the body to be rasped. The anterior and inferior sets of muscles, which are inserted into the corresponding ends of the elastic plate, now contract alternately, and the resulting action is precisely that of a circular saw. It is by means of this apparatus that the Carnivorous Mollusca bore through the shells of the animals upon which they prey; and perforated shells, which have been thus emptied, abound on every coast.

The other appendage of the alimentary canal peculiar, so far as we at present know, to the Mollusca, is what is termed the Crystaline Style, a transparent, usually elongated body, which projects by one end into the stomach, and is lodged for the rest of its extent in a sac formed by a diverticulum of the

* Our Mollusca include the consideration of the tegumentary and genital systems, whose peculiarities, however, are less exclusively Mollusca.
that organ. The Crustacean Style is found in a great number of the Mollusca (Oxylastina, by some supposed to be confused), but each has been observed in only a few Pectinibranch Molluscs, such as Pteroceras, Strombus, Trochus, and Murex. Its function is wholly unknown.

At the alimentary appendages, the Liver in one group, the Ascidians, departs sufficiently from the ordinary plan to deserve particular notice. In these animals (fig. 7, No. 4, &c) it always consists of a series of narrower or wider anastomosing tubes, commencing in cæca upon the outer surface of the intestine, and passing inward and upward, and terminating by a narrow duct, in the stomach. In the Botryllidae the hepatic tubes are remarkably wide.

2. The nature of the Circulatory System in the Mollusca is in some respects a vexed question, more especially as it is not possible to detach the arteries from the veins without leaving any doubt as to the true system of vessels or not. Without entering into any discussion of the various arguments used on both sides of a dispute which is in some respects verbal, we may be permitted shortly to state our own conclusions on the subject.

In the Polypods there are no special circulating organs, if we except the cilia with which the perivisceral cavity is often lined, and which keep up a continual current in the perivisceral fluid; nor do we imagine that any one will insist that the blood of the perivisceral cavity is not a sanus, but has a truly venous lining membrane.

In the Ascidians there is a heart, but it is a simple muscular sac, open at each end, and possessing the extraordinary property of being able to contract more rapidly than any other vertebrate. It thus circulating its blood first in one way and then in the opposite. The blood thus poured out is driven through channels in which assuredly no separate lining membrane is demonstrable. Indeed it is difficult to comprehend how any one can persist in regarding under his microscope these animals as having心脏, but that here, at any rate, the circulation takes place through lacunose, and not through vessels with distinct walls.

In the Brachiopoda a very remarkable vascular system has been said to exist, consisting of two hearts (in Rhynchonella) and a ventricle; the former being in free communication with the perivisceral venous sinuses (perivisceral cavity, notis), while the latter ends in an aorta, whose branches undergo a regular distribution. Such is the circulatory system in the Brachiopoda according to Professor Owen; but our own inquiries have tended to strengthen very greatly the doubts first raised by Mr. Hancock as to the true nature of this so-called circulatory system. It fact these inquiries lead us to doubt whether any one of the organs described in any of the Brachiopoda has anything to do with the circulating system; inasmuch, as, in the first place, we are pretty confident that no arteries are given off from the spicules of the ventricles, as has been said, and think it more than probable that they open external communication with the venous system, either indirectly from structure or directly from observation during life, that the so-called 'hearts' of any Brachiopod are contractile. Thirdly, the multiplication of these hearts to four in Rhynchonella seems not a little to militate against its cardiac nature.

We may fairly conclude then, that for the present, the nature of the circulatory system in the Brachiopoda must be regarded as an open question.

Mollusca Proper.—The doctrine first advocated by M. Milne-Edwards that in these Molluscs the circulatory system is always more or less incomplete, has met with a wide acceptance, but also with no small opposition. So far as the minute transparent Molluscs, which can be submitted to direct microscopic investigation, are concerned, many persons do not understand how the truth of M. Milne-Edwards's doctrine can be questioned. If the term 'venous lining' is to have any meaning but a non-natural one, assurely it cannot be said the truth that anything of the kind exists in the sinuses of Fideides, or of Atlanta, or in those of the Pteropods.

In the larger Molluscs, on the other hand, much depends on the verbal question—what is the definition of a 'vein,' or a vein; and only the direct microscopic inspection of the live animal can, we think, lead to a satisfactory solution of these questions. In the Brachiopoda we cannot understand how the truth of M. Milne-Edwards's doctrine can be questioned. If the term 'venous lining' is to have any meaning but a non-natural one, assurely it cannot be said the truth that anything of the kind exists in the sinuses of Fideides, or of Atlanta, or in those of the Pteropods.

In the larger Molluscs, on the other hand, much depends on the verbal question—what is the definition of a 'vein,' or a vein; and only the direct microscopic inspection of the live animal can, we think, lead to a satisfactory solution of these questions. In the Brachiopoda we cannot understand how the truth of M. Milne-Edwards's doctrine can be questioned. If the term 'venous lining' is to have any meaning but a non-natural one, assurely it cannot be said the truth that anything of the kind exists in the sinuses of Fideides, or of Atlanta, or in those of the Pteropods.
the gills of fishes (especially Amphioxus) more than any other structure to be found in other Invertebrata (the nearest approximation perhaps is in the cloacal branchial of Neuroterus Larve and of some Annelids). Like the wall of the gill-pouch of Lamellibranchiata, that of the branchial sac of Ascidians is fundamentally composed of two elements—a superficial strong framework of branchial bars corresponding with the 'gill-branches,' and a deeper vascular network connecting these. The more obvious peculiarities in the branchial sac of Ascidians, produced by the plaiting of its wall into the so-called branchial folds, which may vary in number from four (Cynthia) to a number so great that the wall of the sac appears crinkled (Phallusia).

3. Ascidians. The existence of a special organ for the urinary secretion has now been demonstrated in all the great divisions of the Mollusca except the Polyzoa and Brachiopoda. The essential feature of the molluscan kidney is the deposition of a quantity of urinary secretion on a free surface, which in all aquatic Mollusca is, by some means or other, freely bathed with water. In Phallusia, for instance, minute rounded sacs, each clothed with a delicate epithelium, and containing one or more concretions, are scattered over the intestine immediately beneath the lining membrane of the atrial cavity. It is probable that the constant current setting through this cavity carries away some portion of the secretion; but the greater part seems to remain, and eventually coats the whole parenchymatous surface of the atrium. Here the secretory part of the apparatus appears to be out of proportion to the excretory. In the Pelecypoda and Heteropoda the reverse relation would appear to obtain. In these animals, in fact, the concretions have not yet been detected; but the excretory apparatus is an elongated sac, which opens at one end by the side of the anus, and at the other communicates with the pericardial blood-sinus. The sac contracts rhythmically and with great rapidity, so that the blood in contact with its delicate walls must be very effectively washed. How far this internal communication with the blood-sinusules is available for the same end, is not at present understood. In the Lamellibranchiata (at least in Unio) the pericardial sinuses is connected anteriorly with the ventral cavity of the branchial sac—the glands of Bojanus—in which a great quantity of concretionary matter may be detected; on the other hand, the outer surfaces of these glands lie in a cavity which admits the water freely by an opening placed anteriorly close to the genital aperture. This cavity clearly corresponds with the coelomate sac of the Pelecypoda and Heteropoda, but no evidence of contractility has yet been observed in it, or in the renal organ itself. Kefer also denies that any direct communication exists between the interior of the kidneys and pericardial sinuses. Nevertheless, it is impossible to be sure of this. However this may be, the arrangement of the kidney in Unio is very interesting, from its close analogy with what obtains in the Cephalopoda, where the 'serous cavities' or the space between the outer and inner layers of the spongy venous appendages attached to one of their walls, correspond exactly with the excretory sacs of the Lamellibranchiata, while the spongy appendages themselves are but the glands of Bojanus in another form. Our limits will not permit of the description of the structure of the renal organ in Nudibranchiata and Pectinibranchiata, but it might readily be shown to resemble in all essential points that of the Lamellibranchiata and Cephalopoda.

D system, essentially a small ciliated pouch placed between the oral end of the hypopharyngeal band and the
show that the intestine extends into the great abdomen thus developed; that it acquires herewith a neural texture; that the tentacles are produced from the margins of its oral aperture; and that the pharynx acquires a large proportionate size.

In the Ascidioidea the neural region remains in a like rudimentary condition, the basmal region undergoing a similar disproportionate growth; but it is next to impossible to ascertain from the study of development whether this hemal outgrowth is formed behind the anus or before it, inasmuch as the intestine has acquired its complete hemal flexure when its parts are first distinguishable.

In the youngest state in which the different organs are distinguishable, the intestine is almost entirely bent up on to the hemal side of the body; the pharynx is a wide cavity (not wider proportionally however than that of a Polyzoa); the tentacles spring from its margin in exactly the same relative position as in a Polyzoa, and there is no atrial cavity. By degrees the pharyngeal cavity enlarges still more, the tentacles remaining comparatively rudimentary (fig. 12, v. 2). Contemporaneously with these changes, the end of the intestine becomes more and more bent down towards the neural surface, and a cavity, which in another Mollusc would be the mantle-cavity, appears around its extremity; a single or two lateral apertures (subsequently uniting into one) are soon formed, and allow this clausal portion of the atrial cavity to communicate with the exterior. At the same time the atrium extends on each side of the enlarged pharynx, detaching it from the side of the body, and enveloping it just as a serous sac invests the surface of a viscera. Ciliated apertures (at first one or two only on each side) now pierce

the wall of the enlarged pharynx, and increase in number until they form a pouch, the branchial sac. Finally, it depends upon the proportional development of the branchial sac, and of the post-abdomen, whether the adult Ascidian shall belong to the Branchial or to the Intestinal subtype.

Unfortunately, we hardly anything of the development of the Branchiopoda; but so far as the Polyzoa and Ascidoida are concerned, it is obvious that the hypothetical modifications of the Archetype do in fact faithfully represent the actual course of development. (See however the remarks, further on, in this connection of the newest-embryon ongrowht in herm Malloccasida and Molletus.)

Development of the Neural Moluscus.—The Lamellibranchiata.—The first step towards the production of the organs from which the lamellibranchs are known, takes place in the development of one portion of its surface into a disc with mixed edges, provided with very long cilia (fig. 12, r. 1). Next in the inner substance of the germ the intestine appears as a solid mass, bent upon itself, towards what the eventual development of the foot proves to be the neural surface; its oral portion being placed immediately behind the ciliated disc (2).

Finally, the hemal surface behind the ciliated disc gradually gives rise to two of the lobes of the mantle, upon each of which is a thin transparent pellicle, the first rudiment of the valve or valves of the molluscan shell. As development proceeds on the neural surface between the primarily approximated oral and anal apertures becomes converted into the large foot and mesosoma of the Lamellibranchs, which serve to lodge the primary shell; the abdomen never becomes developed into a great process as in Gastropoda. The great posterior adductor makes its appearance on the neural side of the intestine, and by its development the latter is thrown up so as almost to appear to have a hemal flexure. The gills next appear as processes of the body within the neural cavity, and therefore have not the remotest homology with the pharyngeal branchial sac of Ascidians, any more than the two aphponal apertures are essentially dependent upon the union of the two lobes of the mantle with the gills and with one another have anything to do with the oral and cloacal apertures of the Ascidians.

Finally, it is said that the ciliated disc becomes metamorphosed into the labial palpi. This is a point well worthy of further investigation; for the arrangement and form of the appendages in Pecten leads us strongly to believe, as we have said, that they are the homologues of the tentacles in the Aplaculidea and Polyzoa. On the other hand, there can be no doubt that the ciliated disc of Lamellibranchs is homologous with the ciliated disc of the gastropod embryos; and if these, there is every reason to believe, are nothing but the specially modified anterior portion of the epipodium. The tentacles of the Polyzoa would thus come to be the homologues of this ciliated disc; but the entire chain of reasoning obviously depends upon whether the ciliated disc does or does not become metamorphosed into the palpi—a position which the more requires confirmation as in the gastropods the ciliated lobes are now known entirely to disappear. How far this be what has been stated with regard to the main steps in the development of the Lamellibranchiata fully confirms the hypothetical derivation of the type from the Common Plan.

Pteropoda and Pulmonata.—In the primary stages of their development no important distinction is to be drawn between the members of this division and those of the last, except that in the Pteropoda the ciliated disc is replaced by two ciliated lobes, one on each side; and in the Pulmonata empty shell sac is replaced by a solid "hemal sac." The primary neural flexure of the intestine in the Pulmonata, and the development of their mantle in front of the anus (that is, the development of an abdomen), are fully demonstrated by the observations upon their embryology. It is important to remark, that in the Pteropoda the ciliated lobes of the embryo do not become the lateral alae of the adult form, but are a portion of the anterior part of the epipodium, which usually disappears in the adult.

It is therefore evident that the development of the mesosoma, as a mass of cartilage, begins much earlier before leaving the egg, and the modifications which its primary form undergoes are extremely instructive. The first organ of the Cephalopod which appear on the larva are (fig. 12, r. 1) the mantle, which is simply a thickening in the middle of the ciliated disc, with somewhat raised edges; around this is a surface representing the mesosoma and foot, at one end of which is the mouth, and at the other or anal extremity are placed two lateral lobes, the remnant of the disc. As development proceeds, each side of the mantle the mesosoma is produced into a longitudinal ridge occupying the precise position of the epipodium.

As development goes on, the hemal surface occupied by the mantle grows out, and becomes a prominent sac, whose free edges of the mesosoma are somewhat more or less elongated, in a direction anteriorly, but for the almost the whole length of the sac posteriorly, give rise to the mantle cavity (v. 2). The intestine passing into the abdomen thus forms more and more bent upon itself, until at last it has nearly made the circle.

With all this the epipodium, remaining rudimentary in its anterior region, becomes a free process on each side posteriorly (representing for a time the alae of a Pteropod), but after a while these processes become reduced to the siphonal canal, the Funnel. In one of the other changes undergone by the margins of the foot are not less remarkable; they are produced from behind forwards into four or five digitations on each side, the anterior pair of which stretch in front of the mouth and unite over it; the digitations elongate more and more, and the mouth is in consequence at last placed in the centre of a sort of inverted cone, formed by the foot and its prolongations—the aceta-

buliferous arms (iv. 3).

Such may be taken as a very short abstract of Professor Kollmann's 'Entwickelungs-Geschichte der Cephalopoden,' and it is needless to point out that it is our hypothetical process of modification of the Archetype into the Cephalopod type, in other words.

The point still necessary to consider the development of the separate families of these Moluscas, as the process, as far as we know, is the same in all. We will take that of a Nudibranch (Antiope cristata) as a type, having recently had occasion to go over it with especial reference to the points here considered the animal.

The end of the process of yelk-division (which, we may remark in passing, results, not in the formation of 'nucleated cells,' but simply in that of smaller and smaller packets of yolk-granules) in this Moluscus, is the formation of a blasto-

Derma, and from the rudiments of the mesosoma the whole embryo next becomes more or less bell-shaped, a sort of rim, with very long cilia, appearing at the broader end, while a minute prominence is seen at the opposite extremity (iv. 1). A straight line drawn from this prominence to the centre of the surface, surrounded by the rim, would have the body of the creature symmetrically disposed around it. On the one surface is a deep pit, formed by the edges of the blastodermic layer; on the opposite a delicate transparent mantle sac is formed, the remainder of the animal. The position of the hemal surface and mantle appears (iv. 3). By degrees the hemal surface becomes more and more promi-

nent, and the shell larger. With this the prominence of the mantle sac grows larger and larger, its shape is changed; the rim becomes more and more laryngeal—so that its position becomes quite asymmetrical (iv. 3, 5). At the same time the ciliated rim from being circular is produced laterally into a lobe on each side—the ciliated lobes; the metapodium makes its appearance behind these as a small prominence; and a delicate operculum is formed between the metapodium. The aperture of the mouth may now be observed behind the ciliated lobes and between them and the metapodium; and the internal substance of the germ is seen to present the outlines of an alimentary canal, consisting of a rounded gastro-haeumatic mass and a narrow intestine, which turns abruptly forwards and upwards, to end on the right side more or less lamellate in the before-mentioned prominence, whose position has become thus extensively expanded.

Two things are obvious in this series of developmental changes. In the first place, the primary symmetry of the embryo; secondly, the gradual asymmetry brought about by the development of that portion of the body which bears the shell, and which is a portion of the hemal surface.

Now this is perfectly in accordance with our hypothetical derivation of the Hemal Moluscus from the Archetype, and is the only point which remains to be proved, that this over-

development of the mesosoma is a result of the presence of an abdomen, that is, as a post-anal portion of the hemal surface.

This view has been taken in deriving these forms from the Archetype; and has been absolutely necessary, and has thus been proved by the presence of an abdomen, that is, as a post-anal portion of the hemal surface.
tion of the haemal outgrowth in the Haemal Mollusca may not be a secondary production, the result of a gradual twisting to one side and backwards of a primarily pre-anal outgrowth of the haemal surface. The facts just detailed with regard to the development of Antiopea would favour this view; but, on the other hand, sufficient attention has not been paid to the process of development of other Gastropods to decide whether it is in these respects identical with that in the Mollusca. The structures of the majority of adult Pectinibranchia and Peripods would lead one to believe that in these forms, at any rate, the haemal flexure has been direct and primary; and it may be that a careful comparative study of development in the Pectinibranchia and Nudibranchia will lead to the translation of the Nudibranchia to the Neural division, the final haemal flexure turning out to be a secondary modification. In the absence of sufficiently conclusive studies of this kind, however, we prefer to be guided by structural considerations, and hence to retain the Nudibranchia provisionally along with the Molluscs with a haemal flexure. It will probably be granted that the doctrine of a Common Plan among the Molluscs, which has been advanced, will have some value as a guide through the masses of their varying organisation—even although the details of this first sketch should turn out to be even in many points erroneous.

MOLOSSUS, [Chitipetra.] MONAZITE, a mineral with the following composition:

| Oxide of Cerium | 28.00
| Oxide of Lanthanum | 23.40
| Thoria | 17.95
| Phosphoric Acid | 28.50
| Oxide of Manganese | 1.90
| Oxide of Lime | 1.70
| Total | 101.50

It occurs in modified oblique prisms. It has a perfect and brilliant basal cleavage. It is only found in small imbedded crystals. It has a brown or brownish-red colour; substances of a similar appearance, but of a very different inclining to resinous. It is found near Platsow in Russia.

MONK, DR. JAMES HENRY, Bishop of Gloucester and Bristol, was born in 1784, and received his early education at Norwich Grammar School and the Charter House. He subsequently entered at Trinity College, Cambridge, of which he became Fellow and Tutor. In 1808 he was chosen to succeed the celebrated Richard Porson as Regius Professor of Greek in the University. It was mainly owing to his efforts in the establishment of the classical department at Cambridge that a Pitt Press was founded. As a scholar of Porson's school he is best known for his editions of the 'Aesopica' and 'Hippolytus of Euriptides, and in the literary world for his 'Life of Bentley,' and the 'Adversaria Bamptonica.' He was appointed Deacon of Peterborough in 1854, and consecrated Bishop of Gloucester in 1830; the see of Bristol was added to his charge in 1836. He died June 6, 1856.

MONKEY-FLower, [Mimus., S. 9.]

MONRADITE. [Minerol., S. 1.]

MONSTROSITY, a term applied to those anomalies amongst plants and animals which present any irregularity in their general form or the form of the organs of which they are composed.

The term Monstrosity is often applied to those anomalies only which are apparent externally, and which produce more or less deformity; but, in a scientific point of view, it includes every variation, either external or internal, in any organ, from its most general or natural formation; and it is in the latter sense that we shall here treat of it.

Monsters were formerly regarded as sports or prodigies of nature, and these ignorant notions, with respect to their true characters, were prevalent among all classes of people until the commencement of the last century, and are even now held by the uninformed. By the physiologist however the study of the various anomalies of organisation in plants, animals, and man, are now viewed as a branch of natural science, and the monstrous development of plants and a minute acquaintance with embryology and structure, have shown that the formation of these different imperfect beings is governed by the same laws which preside over the formation of perfect individuals; the only difference being, that the process of development in the former cases has been perverted, or arrested, or increased in its course during the growth of the embryo or germ.

Monstrosities in the animal kingdom are treated of under the head Monstrosa. We shall give there a brief account of monstrous growths in plants. The study of such growths is not a mere matter of curiosity, as their structure tends not to throw light on the true laws of development amongst plants. Although direct observations are more easily made on animals than on plants, by noting in the latter the facts of their history during growth, it is nevertheless interesting to obtain a confirmation of these facts from the forms which monsters assume, these forms in some way resembling parts of the plant at the stages of growth through which plants pass. In these forms nature presents us with as it were experiments to test the truth of the general laws of morphology.

This subject can perhaps be best illustrated by reference to special instances. To begin with the Leaves. [Lancet.] In the history of the normal development of the leaves, it is found that they are always arranged in an alternate manner, one leaf above the other, but subsequently in many plants, and even families, the leaves become opposite or whorled. In the case however of individuals it is not infrequently happens that the leaves of opposite or whorled-leaved families of plants become alternate. Thus an instance is recorded of Hippuris vulgaris (Mare's-Tail), which in its normal condition has whorled leaves, its leaves arranged alternately in a spiral upon the stem.

In the conversion of the leaf-bud into the flower, one of the earliest changes that takes place is the conversion of the leaves into the organs called Bracts. [Baec.] Instances are very often seen of monstrous forms of plants in which the leaves are not converted into bracts but retain their leaf-like character. This anomaly occurs in the species of Plantago, giving the inframarginal suture a different character to that which occurs under normal circumstances.

The leaf-bud is always seated in the axil of the leaf, but in the case of the bracts forming the involucre of the Cones, the axis is not divided, the flower-buds being united in their axils; but in the case of the monstrous variety of the common daisy (Barn.), known by the name of Hen and Chickens, flower-buds are developed in the axils of the bracts.

Next after the bracts the Sepals are formed in the flower-bud. [Lancet.] It not uncommonly happens that during the growth of cultivated plants, the sepals are found assuming the appearance of leaves. This is especially the case with the cultivated roses. This tendency to recur to the condition of the leaf is seen in the case of Calceolaria, in which the petals are not joined together, and the corolla is of a much greater length than the calyx. Thus, in the case of Calceolaria, the sepals are borne on the lower part of the sepals which thus produces the peculiar character of these fruits, such as the gooseberry, the currant, the apple, and the pear. In these fruits it is not uncommon to find amongst them leaves growing from the surface of the fruit, indicating the tendency of this sepallary part of the fruit to assume the condition of the leaf. The most remarkable example of this tendency of the sepal to assume the condition of the leaf has been observed in the Goat's-Bead (Tropaeolum), in which in one particular case the minute flower which represents the calyx has been found to have assumed the character of the leaf.

It frequently happens where one of the parts of a flower have a tendency to relapse to the foliar condition, that the whole of them partakes of this character. Thus Mr. Austin has recorded very accurately the changes observed in a monstrous form of the White Clover (Trifolium repens), in which in one particular case the minute flower which represents the calyx has been found to have assumed the character of the leaf.

1. Calyx.—This is the most frequently of all the leaves, but when compound leaves are formed the division seems to be as follows: the two large equal teeth, which are opposite the vixillum, form one serrate leaf, and another leaf is formed from the three remaining teeth.

2. Corolla.—It is most frequently reverted to a leaf is the vexillum, and this is a perfect one. Of these leaflets, the als are often seen forming simple leaves, as also the carina; but their perfect union into a ternate leaf is less common.

3. Stamina.—Whatever changes the flower may exhibit,
these organs are always in a state to be recognised, and their reversion to leaves less frequent than in any other part; so that there is more difficulty in determining the number of leaves which go to form this portion. As two ternate leaves form one, it might be supposed that two members of the stamens were constructed out of the same number. The figures represent cases of a stamen reverting to a leaf with a true stamen attached to its stalk on either side; the single anterior stamen, where it reverts, seems always disposed to form a pair of leaf; and it is therefore probable that the ten stamens (9–1) may be formed out of four sets of ternate leaves.

4. Pod.—From the well-known character of the pod and pistil of the common snail, it might be supposed that instead of reversion to leaf would be most frequent in this part of the flower; and a series might easily have been produced which would have represented it in every stage of passage; some of these were given. From these it would appear that the pod is not formed of a whole compound leaf, as either two scales, or two abortive leaves, are constantly to be seen at the base of the imperfect pod on either side; the pod is therefore usually formed out of the middle leaflet. In one flower-head however each division of the pistil-leaf had become a pod, with a distinct stem and the ovules upwards. 

"Ovules seem to be produced only when junction of the edges of the pistil-leaf takes place; in other cases leaflets are produced in the place of ovules.

"The only other part of the floral series has been regularly developed, the Pistil occasionally will take the form of a perfect ternate leaf, and then the axis of the plant is continued through the flower." (Austen, 'British Taxonomy of the Report,' 19th meeting.)

Mr. Astley's last work was a paper read in the same place an instance in which the staminiferous flowers of the Common Maze (Zea Majus) were converted into pistols. In this case we have an instance of the tendency of an organ not to revert to a lower type, but to assume a higher type of development.

It is very frequently the case that stamens relapse to the condition of petals. This is the case with most of the double flowers of our gardens: and in the case of the rose, the peony, the narcissus, and other flowers. Anthers may often be found tipping the petaloid bodies in the centre of the flower. This is seen as a normal condition in the water-lily.

The recurrence of the pistil to the form of the stamens and corolla is not so frequent, as its assuming the form of the leaf. In the double cherry of our gardens this condition of the pistil is frequently presented. It is this same tendency which is seen in monstrous oranges, in which this fruit is spilt up into a number of parts as it possesses carpel-like leaves. [FLOWER.]

The most central organ of the plant is the Seed, and its development is the great object of the production of the flower. The young seed is however but a changed bud, and during the process of its development it sometimes recovers to the condition of the leaf-bud, and produces instead of an embryo a branch.

These instances will be sufficient to show how instructive the study of vegetable monstroussities really is. Many such each have been recorded, and one of the best resumés of the whole subject will be found in Moquin Tandon's 'Teratology Vegetabilis.' [METAMORPHOSIS OF UOANAE.]

MONTAGU, BASIL, Queen's Counsel, was born April 24, 1770, in London. He was a natural son of John Montagu, 2nd Earl of Bristol, and was brought up in his house. His mother was Mrs. May, who was shot in 1779 in the Piazza of Covent Garden, by the Rev. Mr. Hackman, who had fallen in love with her, and destroyed her in a fit of jealousy frenzy. Basil Montagu received his early education at the Charterhouse School, London, of which the Earl of Bristol was governor. He afterwards entered, in 1792, a Fellow of Gray's Inn, and was sent to the University of Cambridge, where he was soon distinguished for his love of literature, and where he remained till after he had taken his degree of M.A. His father died in 1799, leaving him a competent income, of which he made the best use. He was called to the Inns of Court, and was made a Barrister of Lincoln's Inn. After some years' study of the Law, he entered the practice of Chancery. Having selected the Law as a profession, he entered himself of Gray's Inn, where he was called to the bar in 1798, but some years afterwards he became a member of the Inner Temple. He was an active and influential member of the Chancery Bar, and a most zealous advocate of the opinions of Godwin that he had serious thoughts of relinquishing the profession of a lawyer, as 'injuries to society in proportion to the power and attainments of the individual.' James Mackintosh, however, with whom he traveled for some years on the Norfolk circuit, convinced him that the dignity of Godwin was not founded in truth, and he continued in the legal profession. He was a man of great talent, but having devoted his attention chiefly to the bankrupt laws, acquired a high reputation and good practice in that department.

His first work was 'A Glimpse of the Law of Set-off, with Particular Consideration of Cases heard and determined in the Courts of Law and Equity upon the Subject,' 8vo, 1801. It had not appeared many weeks before it was noticed with approbation by Sir Vicary Gibbs, who thus extended the practice of the young lawyer, then almost unknown. His second work was a paper read in the House of Commons, on the Appeal of Inhabitants to the High Court of Chancery, with a Collection of the Statutes, and of the Case argued and determined in the Courts of Law and Equity upon that Subject, 4 vols. 8vo, London, 1803, 2nd edition, 1811. This 'Digest' became a standard work, and many other editions of it were published. He published also 'Law and Practice in Bankruptcy,' 2 vols. 8vo, with 'Supplement,' 1 vol.; 'The Law of Partnership,' 8vo; and 'The Law and Practice of Parliamentary Elections,' in one vol. For this work he was assisted by other legal works and compilations, partly in his own name, partly in conjunction with others, are too numerous to be quoted. Lord Faskine, during his brief tenure of the office of lord chancellor (1806-7) made Mr. Montagu a commissioner of bankruptcy. While holding this appointment, and deriving a considerable income from it, he became so convinced of the delay and expense to litigants of this mode of administering the law, that he published a yearly detail of these injuries. He was afterwards a member, together with Mr. T. Buxton, of a Committee of the House of Commons, finally put as an end to those commissions. A new law was made (1 & 2 Wm. IV. c. 50), under which three judges constituted a Court of Review, and six commissioners exercised functions similar to those of the former; but personally exercising the judicial functions of judges under the great seal. Mr. Montagu was very much dissatisfied with the new law, but he accepted the office of accountant-general in bankruptcy, which he held during ten years. While in this office he demanded from the governors of the Bank of England interest for the bankruptcy moneys in their possession, which had never previously been paid. His demand was at first resisted, but ultimately he obtained 20,000l. for the bankruptcy fund.

This and other negotiations in which Mr. Montagu is best known to general readers are the following:—Selection from the works of Taylor, Hooker, Hall, and Lord Bacon, with an Analysis of the Advancement of Learning," 1802. The analysis is carefully executed, and very useful for those who wish to study Lord Bacon's treatise. 'The Opinions of different Authors on the Punishment of Death,' 3 vols. 8vo, 1809-13. In furtherance of these 'Opinions,' he formed a society for the diffusion of knowledge respecting the punishment of death and corporal punishment, for the abolition of hanging for forgery and other crimes without violence, in conjunction with those of Sir Samuel Romilly, Mr. Wilberforce, and others, and were at length rewarded by complete success, and the great bill sent to the King by a Water-Drinker,' 8vo, 1814. 'The Works of Francis Bacon, Lord Chancellor of England,' 16 vols. 8vo, London, 1825-34. This work was commenced while he was at the university by the translation of Bacon's Latin works, in which he was assisted by Archdeacon Wrangham and others.
MONTAGU. — (Barry Moore, 2d.)

MONTAGU, JAMES, was born at Irvine in Ayrshire, where his father was a Moravian preacher, on November 4, 1771. When only four years of age his parents removed to Grace Hill in the county of Artrim, Ireland, where he was first placed at school. In 1776 he was sent to the University of Edinburgh, and in 1780 to the University of Ayr- shire, to complete his education, and in 1783 his father and mother went to the West Indies as missionaries, where they died in 1790. At Falmouth the instruction was excellent, but the slave life found the young man, at his ten years’ residence there, distinguished himself for nothing "but indolence and melancholy." He had taken a fancy for poetry, which was utterly forbidden in the school; he had clandestinely read ‘Robinson Crusoe,’ which had greatly interested him; and he wrote, when only thirteen, some poor imitations of Moravian hymns. Thoroughly characterised by his teachers as indolent, he had contrived to procure and read a copy of Cowper’s poems, and these he thought he could excel; so he wrote a mock-heroic poem of a similar kind, called ‘The World,’ and this before he was fourteen. He also wrote other small poems; but his teachers, who wished him to become a Moravian preacher, were dissatisfied with his inattention to his studies. In the school-diary of July 3, 1787, it is recorded that, as "J. M., notwithstanding repeated admonitions, has not been more attentive, it was resolved to put him to a business, at least for a time." A situation was soon afterwards found for him with a shopkeeper at Milford. He was afterwards given a great deal of work, knowing that he continued to write poetry and compose music till June 1798, when he ran away. He had only a trifle of money when he started; but on reaching Wentworth, he presented his poem to the Earl of Eldon, who gave him a guinea. He then settled for a twelvemonth at Wath-upon-Dearne as assistant in a general shop. The brethren at Falmouth discovered him, and wished him to return; but he refused. He continued in this situation, silent and recluse, but no doubt pondering over thoughts for which as yet he wanted fitting powers of expression.

He continued to write, and at the end of the year having sent a volume of manuscript poetry to Mr. Harrison, the publisher at Patermoor-row, London, followed it himself. Mr. Harrison declined publishing the poems, but engaged him as shopman. In London he led the same solitary and retired life as in the country. His sole amusement was writing, and he is stated to have never entered a theatre, or even the British Museum, to which he might have thought his habits and disposition would have led him. While in London his first production, a tale in prose, entitled ‘The Chimeras,’ appeared in ‘The Bee,’ an Edinburgh periodical work, in November 1791. He also wrote a novel, which he offered to Mr. Lane, of hinemoa-plems celebrity, who declined it, because the characters swore too much. The novel was never published, but the objection greatly hurt the religious feelings of Montagu, who thought he had only imitated Fielding and Smollett, and was disappointed at not being taken up by the old story-tellers. In the summer of 1792 he returned to his old station, as supercargo at Wath. He did go, but not to remain long. Towards the end of 1792 (having replied to an advertisement for a clerk), he entered the service of Mr. Joseph Gales of Sheffield, who was printer, bookseller, auctioneer, and editor, publisher and proprietor of a newspaper, ‘The Sheffield Register,’ which advocated principles at that time designated as revolutionary.

Montagu formed an attachment to his employer; wrote political articles for the paper; and when Gales, learning that a warrant was out against him, fled to America, started a new weekly paper, on “peace and reform” principles. The first number of ‘The Sheffield Iris,’ appeared on July 4, 1794, which he continued to edit till September 1795. It maintained its existence, with a few changes, till January 1797. This Iris was at first very successful, but it was a singular position for Montagu to fill, with his recluse habits, his mild and almost timid feelings, his dislike to the practical details of business, yet his success, even to the point of his being taken up by the police, so: “I hate politics,” he said, “and would as soon meet a bear as aledger." Almost immediately after starting the newspaper, a poor man employed him to print a few quires of a ballad, for which he was charged eighteen-pence. It was entitled ‘The Comic Wanderer.’ On the fall of Montagu’s Iris he was well conceived; but the attorney-general, Sir John Scott (afterwards Lord Eldon), discovered it to be seditious, indicted the printer, and in January 1795 he was tried at Doncaster, found guilty, fined twenty dollars, and sentenced to three months’ imprisonment. He gave an account in his newspaper of a riot in Sheffield, to quell which the military had been called in and had fired on the people; for this, in 1796, he was again tried, again found guilty of sedition, fined five pounds, and sentenced to four weeks’ imprisonment. During his confinement, which was in York Castle, he wrote a small volume of poems, entitled ‘Prison Amusements,’ which was published in 1797. After his release from prison he returned to London. He was a man of singular shyness, his gentle manners, and perhaps his increasing literary capacity, won him the regard of even his political opponents, and secured him the esteem and love of the rest of his townsmen. He continued to write short poems, several of which are very pleasing; and in 1806 he published ‘The Moravian Preacher,’ a volume containing seven poems, and some other works. All his life he remained a quiet, unpretending person. He lived in London till his death. In 1816 he was presented to the living of Attercliffe in Yorkshire, which he resigned in January 1827.

Montagu’s Life is attested by his poems, but appears less than a complete one; his only remaining work is the volume of poems published in 1827. It contains some of the best in his writings, which are, in general, simple and unaffected. His style is neat and convincing, and his fancy sparkles; but his sympathies with all that is good and holy are ever ardent and sincere; his pathos is touching, and his style melodious, though in his longer poems occasionally too ambitious and magniloquent. Such faults as these are least likely to occur in his shorter poems; and in some of them, as ‘The Common Lot,’ and ‘The Prayer,’ they entirely disappear.

We have pursued Mr. Montagu’s poetical career to the end in order to give a collected view of it. We now return to the few remaining events of his life. His publication of ‘The Wanderer in Switzerland’ led to an engagement on the ‘Ecclectic Review.’ He had few qualities for an able critic—indifference, or at least the feeblest of talents, his praise or blame depended more upon his feelings than his judgment of the character of the work or its literary attributes; consequently one of his earliest reviews was an onslaught on Moore’s early poems, whom he termed in a private letter a ‘false liberal seducer.’ This feeling led him later in life to decline being introduced to Moore, who sought 3 K
his acquaintance. In 1825, as we have said, he resigned the editorship of the 'Iris,' on which occasion a public dinner was given to him by the inhabitants of Sheffield, and funds were subscribed to establish a mission-station in Tobago, which was afterwards conducted by James Moore. Whittington died at the Royal Institution on the 'History of English literature,' a subject on which he was not well qualified to speak, and which therefore fell somewhat dull and flat. Later in the year he published 'A History of Missionary Enterprise in the Nineteenth Century,' a work which he thought was 'an interesting and valuable work.' In 1833 he absolutely declined the office of Professor of Rhetoric in the University of Edinburgh; and in the same year a pension of 150l. was bestowed on him by the Queen, through Sir Robert Peel. In 1836, after having lived forty years in the house occupied by his old employer, Gales, with three of Gales's daughters, who kept the bookseller's shop, on the death of one of them he removed, with the remaining two, to a more convenient residence; and in the same year he delivered a course of lectures 'On the British Poets,' at Newcastle-on-Tyne; and for some years added to his income by delivering similar courses at other places. In 1841 he visited Scotland on a missionary tour. He was received everywhere with great distinction, particularly in the town of Edinburgh, where he received the public reception, and was made a burgess. In 1842 he visited Ireland on a similar errand, saw his old abode at Grace, and while occupied in these religious labors of charity, he was ordained a Moravian minister. In 1852 he delivered a lecture on some Passages of Enion Poetry but little known,' but was so feeble as greatly to excite the compassion of his audience. On April 30, 1854, he died; and on the day of his burial the shops and manufactories of Sheffield were closed, and the whole of the municipal authority, including the mayor, was present. Gales was buried at Sheffield, in twenty-four clergymen. By his will he left 900l. to be distributed to various charities. His memoirs have been published in seven octavo volumes by John Holland and James Everett, to which we have been indebted for most of the facts in this notice.

MONTGOMERY, ROBERT, was born at Bath in 1807. Of his boyish years we know nothing, but he appeared before the world as an author at an early age, conducting in his native city a weekly publication called 'The Inspector,' which had but a short existence. His next publication was 'The Stage-Coach,' dated 1827 in his collected works; and in the same year he issued 'The Age Reviewed: a Satire, and its sequel,' a work which was well received and well rewarded with notes. The work was very delicately directed against irreligion and scepticism, and this has formed the key-note of all his subsequent poems. In 1836, though stated to have been written in 1829, he published the poem 'The Omniscience of the Deity;' it became astonishingly popular, and eight editions are said to have been sold as many months. In the same year appeared another volume, 'A Universal Prayer; Death; a Vision of Heaven; and a Vision of Hell;' a second edition of which appeared in 1839, dedicated to Sharon Turner. 'Satan' quickly followed. All were successful; and encouraged by this success, and the advice and assistance of Mr. S. Turner and the Rev. W. L. Bowles, he entered Lincoln College, Oxford, with the intention of devoting himself to the Church of England. He graduated B.A. in 1833, passing in the fourth class, and M.A. in 1838. His residence at the university provided him with a new subject for his prolific muse, and in 1831 he produced a poem, with historical notes and engraved embellishments, under the title of 'Oxford,' which, though extremely laudatory, was so much controversy and bitterness of spirit that he resigned the incumbency, and returned to London, where he immediately published 'Luther, or the Spirit of the Reformation.' In October 1845 he resumed his ministry at Percy-street Chapel, where he continued till his death. He then began the publication of a number of prose theological works, the issue of which was continued till 1854. Neither was poetry altogether neglected. Besides some smaller works, he wrote several poems during this period, some of which may be found in the 'Works,' subjects, published by Fisher; 'Sacred Meditations and Moral Themes,' 8vo, 1847; 'The Christian Life, a Manual of Sacred Verse,' 12mo, 1849; 'Lyra Christiana—Poems on Christianity and the Church,' 32mo, 1851; 'Lines on Well-Wishing to the Royal Family,' 1842; and 'Devotions in the Christian Sanctuary, A Companion in Verse for the English Prayer-Book,' 1855. On December 3 of this year he died at Brighton, in his forty-ninth year, all his exertions in the cause of religion having been unrecognised by any prevenient in the Church.

That Montgomery's poetical works should have been so successful as they undoubtedly have been, has excited much surprise. As early as 1830 Mr. Macaulay, in noticing a third edition of 'The Omniscience of the Deity,' in the 'Edinburgh Review,' ascribed the poet's success to publishing paffery. That his works have been most inordinately praised is certainly true; but no amount of puffery would have carried a poem through twenty-six editions (which the 'Omniscience' has passed through) if it had not really possessed certain excellencies. But these may be found in the gravely important nature of the subject he has generally chosen, and the class, a numerous one, which he peculiarly addressed. This class, rejecting poetry usually as secular or profane, were pleased by his meditative and stimulating style, by his thoughts which was earnest and sincere; and, prejudiced in his favour, to them his turpitude appeared eloquent, his obscurity assimilated to the mysterious, his vagueness kept him clear from most points of doctrinal difference from them. Montgomery was an inartistic man, often selected without taste and scattered without fitness, kept attention alive; and as in so voluminous a writer it would be scarcely possible not to find some passages containing good thoughts happily expressed, these were pronounced as answers to opposing critics. As a preacher he drew large audiences, and his services were often asked and given in favour of charitable purposes. His style of preaching; in some measure resembled that of his poetry; he was not affected and was grave; but his discourses were accepted as earnestness, his affection as refinement, and his vagueness as a happy generalising. His manners were engaging, and he always acquired the esteem and regard of his congregations, who on more than one occasion gave him substantial marks of his esteem.

MONTICELLITE. [Mineralogy, S.1.] MOORE, THOMAS, was born in Angler-street, Dublin, on the 28th of May, 1779. His father was a small tradesman, and both his parents were Roman Catholics. He was early placed in a private school, and was induced to turn his attention to eloquence, who was fond of dramatic representations, and in whose school R. B. Sheridan had once been. Moore, a quick and lively boy, became a favourite pupil, and as early as 1790 exhibited his talents in reciting an epilogue at a private theatrical entertainment; other dramatic exhibitions were got up by his parents, for which he wrote epilogues or prologues. When he first began to rhyme, he says, he cannot remember; but in 1793 he contributed two poems to the poem 'Nestor,' and in 1795 he was appointed one of the judges, which were inserted, to his intense gratification. In this year the restrictions which prevented Roman Catholics from studying at the Dublin University were removed, though all honours and offices were still denied them. His mother, who wished to be a Roman Catholic, petitioned to enter him at Trinity College in the summer of 1794. At college he pursued the usual studies with tolerable success, gaining several marks of distinction, though, feeling an habitual dislike to the society of his college companions, he went off almost daily to the Dublin coffee house to spend his evening in the society of his friends. In 1796 he published 'An Occasion Speech,' which was approved of by the judges, and for which he received a reward. He continued to write verses for the 'Anthologia' and other periodicals. In 1798 he was elected to a fellowship of the college, and was to have been rewarded for the Ire. With the permission of his father, he went to London to take his degree, and he then became a practising advocate in the courts of Chancery and Common Law, and was in January 1804, 1842. He quit Whittington in May, 1818, and became minister of Percy-street chapel, London; whence he removed, about the beginning of 1836, to St. Jude's episcopal chapel in Glasgow. Here he continued until December 1849, drawing large audiences; but his preaching excited
Born a Roman Catholic, accustomed from infancy to hear the
wrongs of his fellow-religionists descanted on, influenced by
his father's piety, and confirmed in all his habits by the
education he received at the University of Dublin. After
serving by his pretensions to a scholarship in the University
being unavailable on account of his faith, it is little to be
wondered at that he took a lively interest—though fortu-
ately he was too young to be made an ascetic convert—
and pursued the latter vocation. He was examined before Fitzgibbon, the vice-chancellor; but as he
could honestly avow himself ignorant of any plot, he was
discharged. He at length took his degree of B.A., and left
the university; but he had already commenced translation
of the so-called odes of Anacreon, a specimen of which he
blew along the rent of the college, Dr. Kearney, with a
hope to obtain a classical premium. Dr. Kearney thought
the translation good, but that the subject was not likely
to be advantageous to the student. He, however, sent him, in
Middle Temple in London, whither he went, scantily
supplied with money, to study law. In London he was
introduced to Lord Moira, Lady Donegal, and others; he moved
in a fashionable circle; he published in 1801 his 'Odes
of Anacreon'; and of course paid little attention to his
legal studies.
His next publication, in 1802, was 'The Poetical
Works of the late Thomas Littke,' for which he received
60L. They were severely blamed and much read, and their
sentiments were held up to ridicule, for they were
friends, on account of their poetical ability. In 1803,
by Lord Moira's influence, he was appointed to a govern-
ment situation at Bermuda. In January 1804 he arrived
there, having stayed upwards of a month at Norfolk in
Virginia, the residence of Lord Nelson, and desiring to see
him, and in March he left Bermuda, appointing a deputy
to fulfil his functions. He then journeyed over a part of
America, going from New York to Virginia, and back by
Philadelphia and Boston to Niagara and Quebec. He
saw the society in America he was much dissatisfied, and recorded
his sentiments in some satirical poems. In November 1804
he was back in England. Here he expected much from
Lord Moira's patronage, but only succeeded in getting the
appointment of deputy-postmaster in Bermuda, which
was abolished.
In 1805 he published 'Odes and Epistles,' which being
in a similar style to the Little poems brought upon him the casti-
gation of Jeffrey. This occasioned a bloodless duel, the
cuffle of much moment at the time, and led to a firm
friendship between the combatants. He was now leading a
life of fashionable excitement among the aristocracy
of England, a visitor to Lord Moira at Donington Park, and a
constant guest at Lansdowne House and Holland House. As
an accompaniment to his fashionable life, he saw
Bunting's collection of Irish melodies, and at intervals he
had written words for several of them, which he was
accustomed to sign himself with much effect. In 1807 he entered
into an engagement with Mr. Power to produce a
work for which he prepared music and furnished
the words, while Sir J. Stephenson was to provide the
accompaniments. This work was not completed till 1834,
and upon it his true fame will rest. His amatory poems,
though swiftly and playfully written, will always give
to persons of good taste; his satires, however suc-
cessful in attacking ephemeral subjects, will perish with the
events to which they allude; but the melodies, combining
beautiful words, purer morals, and good music, will have
a lasting existence. They have an entirely original character;
they have not the vigor, the truth to nature, and the
deep passionate feeling of our other great lyrical poet,
Burns, but they are never, as he sometimes is, coarse; they
have a playful turn of thought, aoadness of manner,
a play of wit, a brilliancy of fancy, and a richness of admor-
ment, which, though often giving the impression of being artificial,
are always pleasing. In the same class may be in-
cluded the songs written under the title of 'National Airs,'
published in 1816. We cannot however place the 'Sacred
Songs,' which he published in the same year, in the same
category. In them there is a strained adaptation of scriptu-
ral words and ideas, with a lack of earnestness, that ren-
der them distasteful. In 1818, he published, anonymously,
two volumes, 'Anecdotes and Observation's,' probably
'The Sceptic.' They were not very successful. Moore's
muse was too sportive, his fancy too playful, his heart too
genial, for him to excel in severe satire which he here at
tempts.
In 1811 he married Miss Bessy Dyke, a truly estimable
woman, to whom he ever continued fondly attached, and who
was the source of all his parent happiness for the remainder
of his life. In the autumn of the same year he goes of
London, and for some months lived in the city. M.P., or
never. He was at first but moderately successful, ran a few nights, and has
never been repeated, though some of the songs, published
separately in his collected works (from which the opera is
omitted), well maintained his lyrical reputation. Moore had
now made his mark, and went and resided with his family at Mayfield Cottage,
near Ashbourne in Derbyshire, where in 1815 he produced the
'Twopenny Post-Boy,' by Thomas Brown the Younger. The
song was scandalous, at least, as 'Outside the Play' was
directed against the Prince Regent and his ministers, made
them immediately popular, and fourteen editions went through
the press in a twelvemonth.
As early as 1812 Moore had contemplated the writing of an
Oriental romance, as he expressed to his friend Mr. Perry of the
'Morning Chronicle' stipulated for him with Messrs. Long-
man, the publishers, that he should receive for a quarto volume
the sum of three thousand guineas: this was agreed to; but it
was not till 1817 that 'Lalla Rookh' at length appeared. It was
eminently successful; it has passed through many editions,
and it has been frequently translated. It may
however be doubted whether it will contribute to his perma-
nent fame. It is brilliant, melodious, in the 'Fire Worship-
ers,' very a good poem, as is its successor, 'The Dividing
Line.' Characterisation, it is untrue to nature, it is cloying with its
sweetness, it is oppressive with its imagery; the feelings
described are almost uniformly sensuous, and the art of the
composition, painfully apparent. Immediately after the
publication of this work he formed a literary partnership
with Mr. Rogers, and this enabled him to produce
'The Fudge Family in Paris,' a series of poetical epistles,
an entertaining collection of satirical remarks on character
and politics, which was published in 1819. While seeing
'Lalla Rookh' through the press he had removed to Hornsey near London, and here in September 1817 he lost
one of his children. Early in 1818 he learned that his
depth in Bermuda, 'After keeping back from me the proper
receipts of 'Lalla Rookh,' which I have never since seen;
now, it seems, made free with the proceeds of a ship
and cargo deposited in his hands, and I am called upon by a
motion from Doctors' Commons, to be accountable for it.'
The claim was for about 600L of which he hoped to be
recovered from the depth. On this occasion his friends
flocked round him with offers of assistance, but he declined
receiving any, as he preferred paying the money, whatever
it might be, by the earnings of his pen. In 1819 he
accompanied his brother Mr. John Moore to India, taking a
journey to Italy, visiting Rome in company with Chantrey
the sculptor, and Jackson the painter. This expedition was
recorded in 'Rhymes on the Road,' published together with
'Tales of the Holy Alliance,' the same year; they were said
to be 'excellent and entertaining, written in the manner of the
Pococautan Society,' and are serious, political, artis-
tical, and satirical by turns. As the law proceedings
respecting the defalcations were still pending, he did not return
to England; but, settling for his family, took up his abode
at Paris, where he continued until 1825. He purposed
to work hard; but the gaiety of the place, the interruption of
visitors, and probably anxiety as to his ultimate loss, pre-
vented his carrying his intentions into full effect. He
had entered into an engagement to write a life of Sheridan;
but in Paris he found himself, or thought himself, so unfur-
nished with materials, that he gave it up and 'The Loves
of the Angels,' a poem, issued in 1823, and the prose-poetical
romance of 'The Epicurean' (published in 1827), were the
only additions. He returned to London in 1825.
The claim with regard to the Bermuda defalcation had by
this time been settled by Mr. Moore's friends in London,
having been reduced to 74L, which was paid by a cheque
from Lord Lansdowne, and repaid by Moore, clearly from the
proceeds of his 'Loves of the Angels' and his 'Tales of the
Holy Alliance.' He now settled at Sloperton
Cottage, near Bowood, the residence of the Marquis of Lan-
downe; and in 1824 issued the 'Memoirs of Captain Cook.'
Mr. Moore died at one of his visits to London, and his 'opera'
was published in 1825. In 1827 'The Epicurean' was published,
with some fragments of a poem called 'Alciphron,' on the
same materials.
Before this Byron had presented Moore with his
manuscript autobiography, for his especial benefit, but not
to be published till after his death. In this year, in order

3 K 2
MORACEAE, a natural order of Exogenous Plants which were formerly placed as a sub-order of Urticales. The species are shrubs, with a milky juice, sometimes climbing. The leaves are commonly lobed and rough. The flowers are small, mousieous, and collected in heads, spikes, or cattins. The ovules are solitary and suspended. The ovary two lies in the midst of flabby allumen, hooked, with the radicle long, anterior, folded down towards the cotyledons.

Although the Mulberry and Fig grow in Europe, all the Moraceae are extra-European. The species inhabit the temperate and warmer regions, often forming vast forests. The genus Ficus is the most distinguishing feature of this order. [Ficus.] Most of the plant of this genus furnish chincouc. [Cauternouc.] The fruit is always large and globose, and the leaves are the food of the Silk-Worm. [Morus.] Several species of Dorstenia are used in medicine. [Dorstenia.] Other genera of this order yielding useful products are Bruxosoneta and Mascara. [Broussoneta; Mascara, s. 2.]

This order embraces 8 genera and 184 species.

MORCHELLA, a genus of Fungi, one of the species of which is estalble. M. esculenta, the Morel, springs up in orchards, woods, and cinder-walks, early in the spring and summer, and is believed to be most plentiful in places where the ashes are burnt. The Morel is a fruit so considered by many that they cannot persuade of tractable, to draw to woods in order to obtain a crop of morels, of which they are very fond. At last the practice was put down by law. This fruit is a large sponge, firm and subaqueous, with a calyx, or petal-like covering, and a stem, or central staff, from the size of a pigeon’s egg to that of a swan’s hollow, pale-brown, or even gray, and deeply pitted all over its surface, the depressions being separated by raised aca- stomating lines. The plant has a small smell and an agreeable taste, and is employed for various purposes of cooking, both fresh and dried. In the former state it is most com- monly stewed or stuffed with force-meat; in the latter it is employed as an ingredient in sauces. In this country it is of rather rare occurrence.

MOREL. [Morchella, s. 2.]

MORETON BAY. [Australia, s. 2; Wales, New South.]

MORINGACEA, a small natural order of Exogenous Plants, embracing the species of the genus Moringa. They are characterised by the possession of a many-leaved calyx, perigynous petals and stamens, 1-celled anthers, stipitate and consolidated silique fruit, and seeds without albumen. This order is referred by most botanists to a position near Lepospermum; it is however placed by many among the Fuci. They are natives of the East Indies and Arabia.

The root of Moringa pterygosperma has a prunent odour with a warm biting and somewhat aromatic taste. The stem is used as a source of wood, and the leaves of horses, cattle, and Chicot. They are the Ben-Nuts of old writers, from which the Oil of Ben was extracted. It is chiefly used by perfumers as the basis of various scents. It does not readily freeze, and on this account is used by watchmakers. The flowers, leaves, and other parts of this plant are added to curries in India.

MORMONS. [Smith, Joseph, s. 2; Utah, State of, s. 2.]

MORPHOLOGY is that branch of science which treats of the laws which regulate the forms assumed by Plants and Animals. When this term was originally introduced into natural history science, its application was confined to the explanation of the changes which occur in the conversion of the lower into the higher forms and species of plants and animals. It is now however generally recognised as the science of form in the organic kingdoms. Schieden, in his Principles of Scientific Botany, treats of what is usually called the structure of plants, under two heads, that is General and Special Morphology.

The following are his definition and remarks upon this subject:—

"Morphology is the study of the forms of plants, and of their several parts. It is divisible into a general branch, which treats of the whole animal or vegetable body; and into parts, in each of which the various organs in general, and a special branch, which treats of plants according to their principal groups, as well as their individual organs; and this latter branch again is separate into two parallel sections, namely the delineation of external and internal structure, and the peculiar composition of plants and their parts from various tissues."
In my methodological introduction I have endeavoured to show that the external morphology of plants is really the most important element in botany. This view is not, I think, the history of the science will convince any one of the truth of this view; for it is truly wonderful to observe how far it has succeeded, to the almost entire neglect of all other scientific knowledge, in taking possession of the materials by merely examining a plant, whilst we are continually impressed with the importance of the method of considering that the systems which in recent times have taken another path— I allude to the anatomico-physiological—have scarcely affected more than the introduction of extremely trifling changes in the systems. In the instances clearly untenable, and others at the best of very doubtful value; in other words, in most parts, the method of observation has certainly, from the origin of the science, been the basis of all treatises on botany; but those who have thus pursued it have been far from taking a strictly scientific view of the question, and consequently from curing many of its difficulties. This task is two-fold, at once empirical and theoretical. In its first character the study requires us to examine into and characterise the fundamental forms which, as types, or conceptions of generic and specific shapes, constitute the basis of individual forms. In its second character this study has to unfold the natural laws according to which these types are formed, and which control and explain the deviations that occur in individual forms from their prototypes. For the first or empirical part of our researches, we may consider the process of botanical formation, although of a very fragmentary nature; but in the second or theoretical department we have scarcely even an indication to guide us. That the solution of the difficulties must come, we know; and this solution is a scientific one, and here Schwann has certainly shown eminent acuteness in establishing the analogy between the formation of crystals and that of cells; but unfortunately we have not yet brought the law of crystalline formation into the domain of science. Thus far, at the present time we can do no more than specify the problem presented to botany, the solution of which is alone to be expected when the mathematical construction of the formation of crystals lies perfectly constructed. But even this is not enough: we must enter upon all possible construction in a very different way from what has hitherto been done. For this purpose we must consider somewhat more exactly the characteristics of organic form, especially the vegetable, as opposed to the inorganic. The inorganic form, the crystal, is permanent when once formed; it is unchangeable; the individual (the individual existence) is the form itself, and by its solution and change of form a new individual arises. In the plant, on the other hand, the form is not stable or permanent unless the individual is permanent in the individual: between the two hold good only in the simplest cases. The nucleus of a crystal originates in a definite form, and then passes through a series of forms, until it reaches the deduced crystal; whereas it is never finished, and the plant is permanent until the individual is destroyed with the form. Thus certainly it has a very simple history of development, but this continues merely so long as something is still being added to that which is already present, until the whole is completed. The cell is formed in a manner somewhat analogous to this, originating in a definite form, and passing through a series of changes, which, as it appears, only contribute new matter until the form is complete; this then remains stationary until its solution and the consequent destruction of its individuality. It is however wholly different in combined forms, and these it is which, with few exceptions, compose what we term plants. Here a number of cells combine together within definite external limits; but these cells themselves do not enter into the form as dead particles of the mass; they continue to develop new cells, whilst the old ones are partially destroyed: the newly originated cells change, by their arrangement, the form of the whole, and since formation of new parts and destruction of the old are continually going on it is not easy to determine at a given moment, without appearing as anything definitely fixed. As, however, this metamorphosis is constant in its nature, and only occurs in individual parts, we cannot regard each one of the forms resulting from this continual process as a separate and direct result of a modification of the one immediately preceding it; and this peculiar connection brings the whole to us as one individual, which, at its first appearance, may be entirely different in all its parts, both in shape and material, from what it is at last; but in the conception of which we must comprehend the whole series of changing forms, wherein the widely distant members have perhaps no element identical, if we would attain to scientific knowledge, if we would adequately understand the object, and not merely acquire a disjointed, unconnected knowledge, we must go back to the very roots of all these considerations it follows, granting the paramount importance of the morphological method of observation, that we gain nothing by the comprehension of the forms-complex and simple—of the whole plant, but must trace out the law of morphological development, and directly to the conditions which requires, not to an individual complete at any one period, but to the comprehension of the collective constant series of normally changing forms. The conception of genera and species is for the time being not the result of a comparison, but the result of a comparison but also of a connection of the various individual characteristics with each other. In this manner we should lay a firm foundation for the inductions to lead us to the theory of organic morphology, if we could but succeed in completing the analysis of the formation of inorganic forms. As yet we are far from this point, and simply because it is only in the most recent times, and yet very imperfectly, that the importance of the study of the history of development has been acknowledged. But without this, botany would be wholly divested of all scientific principle. This deficiency renders it impossible as yet to treat morphology with scientific logical development, or in accordance with a perfectly systematic mode of arrangement; as will but too soon be seen. For the organic is still but one, although the blame of this is only partially to be imputed to me. It seems however practicable perfectly to state the problem, and to this end I subjoin the following remarks:—We have then to establish morphologic formation, and to delineate the forms themselves. The first must remain for the present a mere problem, the solution of which must be reserved for succeeding times. The second may be accomplished, although imperfectly. I say imperfectly, because, instead of those complete series of derivations, that is to say, series of which we ought alone to treat, we only know a few individual conditions; and therefore the greatest portion of the task still lies unperformed before us. Here we must again be distinguished between what we call the forms, which occur in all or in very many plants of a very different kind, and may therefore especially serve as the foundation of the study of vegetable forms; that is, General Morphology. 2. Series of forms which are only peculiar to definite groups of plants: Special or Comparative Morphology. These two would further branch off into the consideration of form without reference to its composition from the different forms of the external organs: External Morphology; and into the consideration of the manner in which forms are composed according to the principles of nature and society, the normal and inorganic: Comparative Anatomy). This last part falls however away from General Morphology; for all that we can, for the present at least, say is, that every plant is composed of organs, to which the different kinds of organic forms have already been treated. Even with respect to the second part, in regard to Comparative Morphology, it appears to me unadvisable to divide the two sections, on account of our deficiency of material; I shall, therefore, in the examination of the individual groups and parts of plants, subjoin all that is known concerning their structure.
of North America in 1799. His parents were members of the Society of Friends, and he had the misfortune to lose his father early in life. His mother however married a second time when young Morton was thirteen years old, and from his step-father he seems to have derived a liking for the study of natural history. When he was thirteen, he was placed in a counting-house, but his taste for natural science led him to abandon business and enter the medical profession. He was accordingly placed with Dr. Joseph Parrish of Philadelphia, who, although unconnected with any public medical institution, gave him every facility for the management of young men studying the medical profession. He attended the lectures and passed through the course of instruction prescribed for the students of medicine in his native city, and at the age of twenty-one, was admitted a member of the Academy of Sciences (Philadelphia). Soon after this event he sailed for Europe, and, after visiting an uncle—Mr. James Morton of Clonmel, in Ireland,—he repaired to the University of Edinburgh. Here he studied two years, and graduated in medicine in 1823. His inaugural thesis was entitled, 'Tentamen inaugural de Corpore Dolore.' During his period of preparation for graduating in Edinburgh he visited France and Italy, and made a stay in Paris. He returned to Philadelphia in 1824, in time to witness the departure of some of the most eminent literary and scientific men in Philadelphia to join in the illustrious social experiment of Mr. Robert Owen at New Harmony. Morton became immediately an important member of the Academy of Sciences. He commenced his contributions to its transactions by a geological paper. It was entitled, 'Analysis of Tabular Spar from Bucks County.'

He subsequently contributed many papers on Geology and Palæontology; his work on the Mammalia is several of the most important of these papers were published in a separate volume entitled, 'Synopsis of the Organic Remains of the Cretaceous Group of the United States.' This was a very valuable contribution to Geology, and was received with the warmest commendation by the scientific world. He cultivated greatly the natural history sciences, and wrote several papers on zoological subjects.

Whilst pursuing natural history with success, he did not neglect to go to the professional in the Academy. Several previous years, however, were but preparations for the great works on which his reputation as one of the first ethnologists of his day is founded. The line of his research on the races of men lay more particularly in their anatomical conformation, and especially in the structure of the skull. During the winter months, he made collections of skulls and extant, and which is now in the possession of the Philadelphia Academy of Practical Sciences. The origin of this collection may be given in his own words:

"Having had occasion," he says, "in the summer of 1830 to deliver an introductory lecture to a course of anatomy, I chose for my subject 'The Different Forms of the Skull as exhibited in the Five Races of Men.' Strange to say, I could neither buy nor borrow a cranium of each of these races, and I found myself without a single specimen of the Mongolian or the Malay. Forbidding impressed with this deficiency in the most important branch of science, I at once resolved to make a collection myself. The result of this determination was not only his great collection, but the two magnificent works entitled 'Crania Americana,' and 'Craniys Egyptiaca.' These works embrace not only an account and illustrations of these skulls, but general ethnological observations on the races of men. The collection on which these works were founded was made by using the human crania, collected from all parts of the world, 278 crania of mammals, 271 of birds, and 88 of reptiles and fishes.

Although in his earlier writings he maintained the specific unity of the human race, in the latter part of his life he was led to doubt this view. He, however, believed the existence of a variety of species among men. This view has been strongly insisted on, in a work published since his death, under the title of 'Types of Mankind.' This work, edited by Messrs. Nott and Glidson, contains a large mass of matter by the editors and others, with many "Excerpts" from Morton's inedited papers. In these be undoubtedly arows his belief in an "aboriginal plurality of races;" and expresses his conviction, that man will yet be found in the fossil state as low down as the Eocene deposits, and that he walked the earth with the megolonyx and plesoatherium. It is only right to add that these views have not been generally received; and that our most distinguished ethnologists, palæontologists, and geologists have not ascribed his theory to lack of scientific judgment. Dr. Morton died at Clonmel, after a short illness of five days, on the 17th of May, 1851.

MOSANDERITE. [Mineralogy, S. 1.]

The following is an account of the structure of the Male Mosquito, the Mosquito of the Americans, by an American observer.

'The male mosquito differs considerably, as is well known, from the female; his body being smaller and of a darker colour, and his head furnished with antennae and palpi in a state of greater development. Notwithstanding the fitness of his organs for predatory purposes he is timid, seldom entering dwellings or annoying man, but restricts himself to damp and foul places, especially sinks and privies. The female, on the other hand, gives greater extension to her appetites, and her approach to human beings is accompanied by considerable disturbance and vexation during the summer and autumn months.

'The head of the male mosquito, about 0.67 mm. [millimetre] in length, consists of 14 joints, 12 short and nearly equal, and 2 long and equal, terminal ones, the latter measuring together 0.70 mm. Each of the shorter joints has a frassinated skeleton with an external investment, and terminates simply posteriorly, but is encircled anteriorly with about 40 papillae upon which are implanted long and stiff hairs, the proximal sets being about 0.70 mm. and the distal ones 0.70 mm. in length; and it is beset with minute bristles in front of each joint.

'The two last joints have each a whorl of about 30 short hairs near the base.

'The female the joints are nearly equal, number but 13, and are placed at equal intervals round the base. Here, as well as in the male, the parts of the antenna enjoy a limited motion upon each other, except the basal joint, which, being fixed, moves with the capsule upon which it is implanted.

'The space between the inner and outer walls of the capsule, which we term conveniently the auditory capsule, is filled with a fluid of moderate consistency, opalescent, and containing minute spherical corpuscles, and which probably bears the same relation to the nerve as the lymph in the vascular system.

'The genus of the antennae proceeds from the first or cerebral ganglion, advances towards the pedicle of the capsule in company with the large trachea which sends its ramifications throughout the entire apparatus, and terminates immediately posteriorly. Here the nerves divide into two portions. The central nerves continue forwards into the antenna and are lost there; the peripheral ones, on the contrary, radiate outwards in every direction, enter the capsule space, and are lodged for more than half their length in sulci wrought in the inner wall or cup of the capsule.

'The female the disposition of parts is observed to be nearly the same, excepting that the capsule is smaller, and the last distal antennal joint is rudimental.

'The auditory sense differ much in the two sexes, but the palpi, although consisting in both instances of the same number of pieces are very unlike. In the female they
are extremely short, but in the male attain the length of 2½ inches; while the proboscis measures but 2½ mm. They are curved upwards at the extremity.

"If an organ of hearing, similar to that described by Treviranus as belonging to the Blatta orientalis, exist in the head of the Mosquito, the tympanum must be of exquisitely minute size, and the animal's organs of hearing, as far as they can be perceived in any way, other than by the animal's own perception, can have no function. The small size of the organ, therefore, is equally to be regarded in the male and female, as the external auditory meatus is situated in a cavity, the floor of which is bounded by a cornical plate, and the margins of which are studded with very acute hairs; and we are obliged to look for some organ which may answer the requirements of an effective auditory apparatus.

The position of the capillaries, or the disposition of the organs of the function which we assign to them: besides which there present themselves in the same light the anatomical arrangement of the capes, the disposition and lumen of the hairs, the fitness of the expanded whorls for receiving, and of the jointed antennae fixed by the third pair of legs, or by the proboscis, formed by concomitant modifications. The intra-capsular fluid is impressed by the shock, the expanded nerve appreciates the effect of the sound, and the animal may judge of the intensity, or distance, or source of sounds, by the quantity, or proportion, of the flexure, or by the concavity of particular fibers of the stiff hairs, according to their lengths; and of the direction in which the modulations travel, by the manner in which they strike upon the antennae, or may be made to the sense of projection, in consequence of an opposite movement of that part.

"That the male should be endowed with superior acuteness of the sense of hearing appears from the fact, that he must seek the female for sexual union either in the dim twilight or the dark night, when no other means of attracting his attention but the humming noise can serve him as a guide. The necessity for an equal perfection of hearing does not exist in the female; and accordingly we find that the organs of the one attain to a development, or size, which is much more advanced in the male. In these views we believe ourselves to be borne out by direct experiment, in connection with which we may allude to the greater difficulty of catching the male Mosquito.

"In the course of our observations we have arrived at the conviction that the Mosquito is surpassingly capable of receiving the impressions by which the organs of touch in the female; for the palpi are extremely short, while the antennae are very moveable, and nearly equal the proboscis in length. In the male however the length and perfect development of the palpi would lead us to look for the organs of touch in him, for we find the two apical antennal joints to be long, moveable, and comparatively free from hairs; and the relative motion of the remaining joints very much more limited." (Dr. Christopher Johnston, Quarterly Journal of Microscopical Science.)

MOTACILLA, MOTACILLINAE. [BIRD BIRD; BLUE BREAST; SYLVIAAE; WAGTAILAE.]

MOTELLA, a genus of Fishes belonging to the family Gudgeon. It has the following characters: Body elongated, cylindrical, compressed posteriorly, the first dorsal fin very slightly elevated, delicate in structure, scarcely perceptible; second dorsal and anal fins long, continued nearly to the base of the caudal fin. M. vulgaris, Mustela marina (Ray), Gadus tricirratus (Bloch), the Three-Bearded Rocking, Sea-Loche, Whistling Fish, Three-Bearded Cod, Three-Bearded Gade, has the following characters: The length of the head compared to the length of the body alone, without the caudal ray, is as one to two; the depth of the body equal to the length of the head; the first dorsal fin delicate in structure; the first ray elongated, the rest hair-like; the second dorsal fin commencing immediately behind the end of the first, and reaching along the edge of the tail; the first anal fin commencing immediately behind the first ray of the caudal fin; and the second anal fin commencing immediately behind the first ray of the caudal fin, the short of one to four; the depth of the body equal to the length of the head; the first dorsal fin delicate in structure; the first ray elongated, the rest hair-like; the second dorsal fin commencing immediately behind the end of the first, and reaching along the edge of the tail; and the second anal fin commencing immediately behind the first, and the end of the spine portion of the tail; the anal fin commences immediately behind it, is one-fourth less in length than the second dorsal, and ends on the same plane with it; the tail moderate in size, and rounded at the end. The fins in number are—two D. 55; P. 20; V. 7; A. 49; C. 18. The head is depressed; the mouth wide; the jaws nearly equal, but when separated the lower jaw is the longer, with one barbule at the chin; a mixture of large and small rays in each fin; with one barbule on each of the side middle, between the lip and the nostril; of the upper lip crenate; the irides golden yellow; the anterior portion of the body of the fish cylindrical, or slightly depressed; the tail compressed; the general colour of the fish bluish, with a white or yellow-brown spot, on the top of the head, along the back, the pectoral, dorsal, and caudal fins, with rich chestnut-brown; the lower part of the sides, the ventral and anal fins pale yellow-brown approaching to white, and without spots.

Young specimens are of a uniform brown colour, until they have acquired 6 or 7 inches in length; in this condition they are the Mustela alta of Ray. (Yarrell.)

This fish is common on the coasts of Cornwall, and also on the coasts of Ireland.

M. eimbria (Gadus eimbria, Linn.), the Four-Bearded Rocking. This fish has been taken in Scotland, and is common in the Baltic and the southern coast of Sweden.

M. aquascirrus (Gadus mustela, Linn.), the Five-Bearded Rocking. It is common on the southern part of the southern coast. Its habits resemble those of the Three-Bearded Rocking, and by some naturalists it is regarded as a variety of that species.

M. platys (Clialista gurus, Conch.), the Mackarel Midge. This fish has been taken on the coasts of Cornwall by Mr. Conch. It dies instantly on being taken out of the water. It is like the young of some of the other species, but it has not been observed to grow.

M. argenteus (Montagu), the Silvery Gade. This fish is a miniature representative of the Three-Bearded Rocking, as the last is of the five-bearded species. It was first described by Montagu, and is admitted as a distinct species by Yarrell.

MOULMEIN, a town and port in the Tenasserim Provinces, which form a part of the British possessions on the eastern side of the Bay of Bengal. Moultine is situated near the Gulf of Martaban, at the confluence of the rivers Salong, Amsterdam, and Goyang, in 10° 30' N. lat., 97° 44' E. long.; the three rivers when united are called the Moulmein River. It is 10 miles S. by E. from Martaban, and 30 miles N. by E. from Amherst. [Amherst.] Moultine has a good harbor, which admits vessels of 600 or 600 tons. Being situated near the entrance of the Ganges, its trade is free from duties of internal and export, and it has drawn away much of the commerce which belonged to Martaban, and has in a great measure superseded Amherst. The population is estimated at upwards of 10,000. The exports are tea, lumber, rifle, tobacco, ivory, rice, silk, ass, and China stuft. The imports are cotton goods and other manufactures.

MOUNTMELICK. [Queen's County.]

MOUNTRATH. [Queen's County.]

MUSIC ACID. [Oxynkry, S. 1.]

MUCORACEAE, an order in Lindey's alliance Fungalae. The species have a floccose thallus and the sporae surrounded by a vesicular veil or sporangium. They are amongst the smallest forms of Fungi, and attack decaying vegetable and animal materials. They are frequently known by the name of Mouls. [Mouldiness; Fungi; Endoptya, S. 2.]

MUDARIN. [Chymist, S. 1.]

MUDGILL, WILLIAM. [R.L.S. A major-general in the army, the third in succession of the directors of the series of geodetical operations, which resulted in the Triangulational Survey of Great Britain and Ireland, the production of the 'Ordnance Maps' by its means, and the measurement of the English Arc of the Meridian, the history of family and hereditary title, and the occupation of certain offices by a succession of gifted men, have frequently been illustrated in this work. They are again forcibly recalled by the name now commemorated. The Mudgill family, being Chinese, the Mudgill Zee, in the Grammar School at Bideford, in Devonshire, and vicar of Abbotsbath, afterwards a prebendary of Exeter and vicar of St. Andrew's, Plymouth, was the author of an 'Essay for New Version of the Psalms,' and volume of sermons, published in 1727. He died April 3rd, 1760, and was eulogised by Dr. Johnson, whose intimate friend he had been. Thomas Munro, his second son, born at Exeter in
MUL

1716, was apprenticed to the celebrated watchmaker, George Graham, and became himself one of the most eminent mechanists of his time: a select committee of the House of Commons, assisted by a committee of men of science, philosophical instrument makers, and watchmakers, including Atwood, Ramsden, Troughton, and De Luce, declared in 1730, that Mr. Mudge was one of the first watchmakers which this country has produced.

In consequence of a report made by the select committee, a reward of 3000l. was granted by parliament for his improvement of the mathematical sciences. In 1735 the decease took place shortly after, in 1794. A full account of his invention, and of the circumstances in the history of chronometry connected with it, will be found in a work published by his son, Thomas Mudge the Younger, entitled 'The Virtues of the Mathematical Sciences, and the Savings of Time, as practised by Mr. Thomas Mudge,' Sec., Lond., 1790, 4to.

The fourth son of the vicar of St. Andrew's was Dr. Jonas Mudge, F.R.S., for many years an eminent physician at Plymouth, who practised in the inoculated small-pox, and on contagious coughs. But he acquired a higher reputation in practical optics, founded on a paper in the 'Philosophical Transactions,' vol. xlvii., "containing directions for making the best composition for the metals of reflecting telescopes, together with the processes of grinding, polishing, and giving the great speculum the true parabolic form." For this paper, in which an anticipation of Newton was verified, the council of the Royal Society awarded him the Copley Medal for the year 1777, 4th December, 1802, Sir G. Baird, then president, delivered one of his celebrated discourses.

William Mudge, the subject of the present article, son of Dr. John Mudge, was born at Plymouth in 1762, and having received his principal education as a cadet at the Royal Military Academy at Woolwich, was appointed to the Royal Artillery, in which corps he served abroad for some time. After his return to England, the Trigonometrical Survey of England and Wales, which had been commenced by Major-General Warburton, was conducted, by Mr. C. Hutton, under the superintendence of Lieut.-Col. Edward Williams, R.A., Lieut. Mudge, also on Dr. Hutton's recommendation, being appointed his personal associate in the work, and being promoted shortly afterwards to the rank of Captain. This survey, which had suffered some interruption after the decease of the former director, was actively resumed in 1791. In the 'Philosophical Transactions' for 1796 and 1797, are two papers of great length, by Lieut.-Col. Williams, Captain Mudge, and Mr. Isaac Dalby, giving an account of the Survey as carried on from 1791 to 1796. Not long afterwards Captain Mudge succeeded to the office of superintendent, and in 1796 he became a Fellow of the Royal Society. In the 'Philosophical Transactions' for 1800, he continued the account of the Survey during the years 1797, 1798, and 1799; and having attained the rank of Major, R.A., he gave in the volume for 1803, 'An Account of the Measurement of an Arc of the Meridian, extending from the Place of Seeing the Eclipse . . . to Clifton, in Yorkshire . . . in course of the operations carried on for the Trigonometrical Survey of England, in the years 1800, 1801, and 1802.' Major Mudge, who united with energy of character, mathematical talent and culture, and the valuable faculty of readily observing and appreciating the existence of corresponding qualities in others, recognised a kindred spirit in Lieutenant Colby, R.E., conferred an inestimable benefit upon the national work by furnishing his services as his chief personal assistant. In 1802, with Colby's assistance, he measured the base on King's Sedgmoor; in 1806, that on Rhindall Marsh; and during his superintendence a third base was measured by Colby on Behleva Links, near Aberdeen, in 1817. [Costley, Thomas, S. 234.]

In 1798, as a kind of semi-official publication, in 4to, vol. i. of 'An Account of the Survey from the Commencement in 1784, to the end of the Year 1798,' revised from the Philosophical Transactions,' by Captain Mudge and Mr. Dalby. The second part, for the year 1801, was edited by Captain Mudge alone, and continued the account to the end of the year 1799; it was, in fact, a separate issue of the paper communicated to the Royal Society by Mr. Mudge, and noticed by Lieut.-Col. William Mudge, of the Royal Artillery, F.R.S., and Capt. Thomas Colby, of the Royal Engineers, published in 1811, contains the account of the Survey, as carried on from 1800 to 1802. But a very small proportion, however, of the whole body of observations was contained in the volumes, and no further account of the survey was made public until long after the decease of Mudge, when, in 1842, his successor Colby published all the observations made with Ramsey's zenith sector. The maps, however, known as those of Mudge, had already been printed in 1805; and a mile, were first produced under Mudge's superintendence, and were issued from time to time (after an interval during the war, in which they were withheld from publication), until they were finally abandoned, as having the highest value in reference to the topography of the country.

Whilst General Mudge was superintendent, but by the personal exertion of Captain Colby, the principal triangulation of the survey was extended, as just indicated, to the north of Scotland. This was the first step in which it had been carried on under his orders in former years, his successor had to correct errors and supply many omissions. These, as we are informed by competent authority, "had resulted from the hurried manner in which the work was performed, from the very imperfect means placed at General Mudge's disposal, and from the want [since supplied] of a legislative enactment for the preservation of the various trigonometrical observation stations throughout the country, which want sometimes led to a destruction of the observations at different points; so that, all things taken into consideration, it is rather to be wondered at that the work should, generally speaking, be so good as it is known to be." [Mem. Roy. Ast. Soc., vol. xxii., p. 213.]

On 3rd September, 1803, Lieutenant-Colonel Sir Robert appointed lieutenant-governor of the Royal Military Academy at Woolwich; into the administration of which he was stated to have introduced many excellent regulations, which were afterwards extended, and directed, to the Military Seminary for the education of the East India Company at Addiscombe. In addition to the public employments and distinctions which have been mentioned, he was a member of the Board of Longitude, a Fellow of the Society of Antiquaries, a member of the Royal Society, an honorary LL.D. of the University of Edinburgh. The Royal Academy of Sciences of Paris elected him a correspondent, and the Academy of Sciences of Copenhagen, a Fellow. He died at his house in Holles-street, London, on the 17th of April, 1821, in his fifty-eighth year, leaving a widow, with three sons and a daughter.

One of the sons, Richard Zachary Mudge, who entered the army in 1807, and served in the Peninsula, became eventually a lieutenant-colonel in the royal engineers and F.R.S. He also was attached to the Trigonometrical Survey, in which, after Captain Colby had been appointed superintendent, he was entrusted for some years with the local charge of the 'drawing-room' in the Tower of London—where the principal triangulation was kept and the maps actually constructed—during the absence of his chief on other duties. He afterwards retired from the service, and entered into business as a banker in Devonshire. He died at Teignmouth on the 24th of September, 1824, aged sixty-five.

MUDWORT, the common name of the species of the genus Limosella. This genus belongs to the natural order Scrophulariaceae. It has 5 cleft calyx; a 5-5 lobed equal corolla; a globose 4-valved capsule, with a central placenta, free, or connected with a short discintemp below, 1-celled.

L. aquatica is the only British species. It has lanceolate spathulate leaves on long stalks; pedicels axillary, crowded, orange; the flowers small, 4-coloured flowers. It is found growing in mucky places, where water has stagnated.

MULLET. [Mullus; Mullet, S. 8.]

Mullus, a genus of fish, is appropriated to the group Anostomognathi and the family Percidae. The species have the body thick oblong; profile of the head approaching to a vertical size; scales large, deciduous; two dorsal fins widely separated, the rays of the first spiny, those of the second soft. The mouth is large, so as to be practically horizontal, with the labial papillae the lips of the lower jaw; branchiostegal rays 4. There are two species of this genus found in Europe, and both are inhabitants of the seas of Great Britain. M. Austriacus, the Striped Red Mullet, or Striped Mullet, has this form: Length in inches: D. 7—11 $ 13; P. 17; V. 1 + 6; A. 2 + 6; G. 13.

The forehead, nape, cheeks, and operculum are eared
with scales; irides pale-yellow; mucous-pores abundant; the colour of the body is from a pink to a bright-red; the membrane of the first dorsal-fin is tinged with yellow; those of the second is clearer, that of the ventral-fin is furnished with a pointed scale; the vent placed under the commencement of the second dorsal fin.

The Striped Red Mullet is abundant on the southern coast of England, and as far north as the eastern and northern coasts. This fish is good eating, and is sent in large numbers from the London market. In the month of August, 1819, 5000 were taken off Weymouth, and in one week during the month of May, 1831, 10,000 were sent from London to Weymouth. The Striped Red Mullet was a favourite dish amongst the ancient Romans, and large prices were paid for them. "A fish of 3 lbs. weight produced a considerable sum to the fortunate fishermen, while the cost of a fish of 44 lbs., says Martin, was ruinous. A Mullet of 3 lbs. weight was considered a sum equal to 45l.; one still larger 64l.; and even 240l. were given for three of unusual size, procured on the same day, for a repeat of more than usual magnitude." (Yarrell.) On the coasts of Great Britain this fish seldom exceeds 14 inches in length.

The Striped Red Mullet spawns in the spring, and the young are 6 inches long in October. Their food consists of the softer crustaceous and mollaceous creatures. The cirri, with their numerous attached organs of feeling, whereby these animals are enabled to distinguish their food. Mr. Yarrell says, "On dissecting these appendages in the Mullet, the Common Cod, and others, I found the mucous cartilage invested by numerous longitudinal muscular and nervous fibres, and covered by an extension of the common skin. The muscular apparatus is more apparent in the Mullet, the nerve portion most conspicuous in the Cod. These appendages are to them, I have no doubt, delicate organs of touch, by which all the species provided with them are enabled to ascertain, to a certain extent, the qualities of the various substances with which they are brought in contact, and are analogous in function to the feeler, with its different branches and appendages, in certain birds which probe for food beyond their sight; and may be considered another instance, among the beautiful provisions of nature, by which in the case of fishes feeding at great depths, where light is deficient, compensation is made for imperfect vision." ("British Fishes," vol. i, p. 34.)

This and the next species must not be confounded with the Gray Mullet, which belongs to a very different family of Anchothryptygine Fishes. (Hunnu.)

In the Mullet, the Salmunlet, the Red Salmunlet. This fish is much rarer on the British coasts than the last. They seem to be equally abundant in the Mediterranean. The fin-rays are as follows: D. 7—1 + 8; P. 18; V. 6; A. 1 + 5; C. 15. The scales are somewhat shorter than in the last and present some structural differences.

(Yarrell, History of British Fishes.)

MURÉNOIDES (Laopède), a genus of Fishes belonging to the section Anchothryptyrp, and the family of Gobiidé. The species have been included under the genera Blennius of Linnaeus, and Giomellus. They have the head small, mould obtuse; body elongated, smooth; scales minute, covered with a mucous secretion; dorsal fin extending the whole length of the back, the rays simple; ventral fins very small; teeth small, pointed, detached.

M. guttatus, the Spotted Gurnell or Butter-Fish, is distinguished from its congener by the consistence and quantity of its bones, each by which its sides are covered. It is known from the true Blennies by its dorsal fin being but little elevated above the line of the back, and by its elongated, slender, and compressed body, from which circumstance it has obtained the name of Swordick in Orkney and Shetland. In Norway, it is supposed resemblance to the blade of a sword. It is a common fish on the coasts of Great Britain, where it is often found in the little pools left by the tide. It feeds on small Crustacces and the spawn and fry of other fishes. In Greenland it is eaten, but Red Indians are not much fond of it in this country. Its flesh being hard. The length of the head is equal to the depth of the body, and is, when compared with the whole length of the body and head of the fish, without including the tail-fin, as one to eight. It is said to be the length of 10 inches, but its more frequent length on the British shores is from 5 to 7 inches.

Mr. Yarrell states that the Spotted Gannel of America is identical with the British fish.

MUREXAN, MUREXIDE. (Géométr., 2, 1.)

MUSCALES, Aneuranous Plants in Lindley's arrangement of the Vegetable Kingdom. It includes two divisions:—1. Hepaticae; 2. Musci. The Hepaticae include the orders Ricciaeae, Marchantiae, Jungermanniellae, &c. The Musci include the orders Anthocrysea and Bryaceae.

MUSCARDINE, the name given to a disease to which silk-worms are subject, and which often causes great injury to those who cultivate these animals for the sake of their silk. This is the most unfortunate of a fungus belonging to the genus Botrytis, and has been named by Balsamo and Montague B. Basistina. This plant, which is characteristic of the disease, can be propagated by the introduction of spores into a healthy caterpillar. The result of the change which is produced upon the blood and tissues of the animal is its death. This disease is much more common some years than others. It frequently spreads to other insects; and the caterpillars of other Lepidoptera can be inoculated by the spores that are disseminated. When once the disease has appeared there seems to be no means of checking it. The best mode of prevention is to take care that the caterpillars are not over-crowded, and that they have a sufficient supply of fresh food. The predisposition to this disease seems to depend upon the nature of the food; and the same causes as those which act upon the human system, and render it favourable to the attacks of epidemic diseases. (Robin, Hist. des Végétaux Parasites.)

MUSCAT, a port town on the east coast of Arabia, in the province of Oman, situated on a peninsula which is joined to the island of Muscat by a reef of rocks, in 33° 43' N., lat., 58° 40' E. long., and has about 60,000 inhabitants. High lands to the south and west, and the island towards the east shelter the harbour, the entrance to which is from the northward, and protected by forts on each side; within there is room enough for a large fleet to moor in 4 or 5 fathoms water. A fort close to the town, and two other forts on the western side of the harbour command the whole of the port. These forts are made of stone, and are strongly fortified. The houses are only one story high with the exception of some handsome stone buildings erected by the Portuguese. There are also some houses built in the Persian style, and an aqueduct.

Muscat is a great commercial entrepôt, and has a very active trade. A large number of ships belong to it, and trade to British India, Sumatra, the Malay Peninsula, the Red Sea, and eastern coast of Africa, the Comoro Isles, and Madagas- car. Imports from Arabia, Africa, and China, are very considerable. British and French merchants trading at the Persian Gulf stop at Muscat to sell and purchase goods. Besides its principal, there are many subordinate and less active trade with the Arab tribes of the interior. The principal articles of the commerce of Muscat are—assassifruits, almonds, raisins, pistachio nuts, sweetolives, gum sammoniac, sulphur, gum copal, and saltpetre. Other articles are frankincense, pearls, galluuts, coffee, cocoa-nut oil, galba- num, bides, cotton-wool, mother-of-pearl, gun, bees-wax, raw silk, indigo, tortoise-shell, rhinoceros-horns, pepper, cochineal, cinnamon, sugar, rice, sandal-wood, dates, salmon, wheat, horses, salt, dried fish, &c. Most of these articles are imported in Arab vessels from Persia, Zanzibar, Africa, and Western Arabia, and are exported to India, the Mauritius, Bourbon, Calcutta, Bombay, America, France, Zanzibar, &c. The tissens imported at Muscat are British and some long-cloths, British calico-prints, India shawls, Chinese silks, &c. The country near the town is barren; but por- visions, fruits, vegetables, and fresh fish are abundant in the markets. Bulls, sheep, and fowls are to be had at a reasonable price. The average imports into Muscat are probably under-estimated at a million sterling. Imports pay a duty of 5 per cent. if coming from Arabia, America, or Great Britain; 4 per cent, if coming from Bourbon. No Articles are exported on. There is a large town called Muttra, 3 miles to the west, and between Muscat and Muttrah. There is a good road between the two places. At Muttra vessels can be hauled ashore. In the interior there is another large town called Rostaa.

Muscat was a place of considerable trade before the arrival of the Portuguese in the Indian Ocean, and it was then
subject to Ormus. Alberquerque took it in 1607, but had immediately to put down a bloody insurrection of the Arabs. On the eastern shore of Muscat, which was the principal centre of trade in this part of the East, and yielded enormous profits to the Portuguese, who held the town till 1648. During this interval they built the fortifications and greatly improved the town, having erected a handsome church, a college, and many mosques. The indigenous inhabitants, numbering many thousands, are of thin and stunted build, and are very much addicted to the smoking of pipes, and to drinking fruit wine mixed with water and much sugar. They have been reduced to the lowest condition by the Portuguese, who after being gorged with wealth the Portuguese treated the natives so badly and put so many restrictions on their commerce, that they took up arms and drove the foreigners from their country. Many unsuccessful attempts were made by the Portuguese to recover the town.

Left to themselves, the Arabs of Muscat—expert seamen, skilled in the use of fire-arms—soon raised a maritime force which overawed not only the neighbouring coasts, but also the Red Sea. The Indian traders, who had established themselves masters of several places in the Persian Gulf, and were threatening Goemboom; and the British government, acting upon the report of their resident at that place, proposed to send out an armament to clear the Indian seas, and "to root out that nest of pirates the Muscute Arabes." In 1709 the Arabs obtained permission to build ships at the ports of Pegu from the king of that country; and their fleets, comprising ships of from 30 to 50 guns, annoyed trade in the Indian Ocean. As a matter of fact, the Portuguese only had a handful of ships on the road from Canton to Muscat along the Malabar coast. With the Persians they were almost continually at war; although Persian traders were always permitted to trade at Muscat or any of its dependencies, all Persian ships of war were considered fair game. Since the end of the 16th century there have been, and there still are, sailing vessels in the Gulf, which have forsaken their piratical practices, and have confined themselves principally to commerce; and during the rule of the present Imam the territorial dominions, naval power, and commercial importance of Muscat have increased so rapidly, that it entitles him to be numbered among the great powers of the world. He has commercial treaties with Great Britain and the United States, and has opened intercourse with several European and Oriental states.

The Imam of Muscat claims as his possessions in Asia all the south-east coast of Arabia from the frontier of the British settlement of Aden to Ras-el-Had; all the territory of Oman along the east coast of Arabia, the sea-coast and islands in the Persian Gulf, including the Bahrain Islands and the pearl-fishery contiguous to them; and the coast of the Makan. In Africa he claims sovereignty over all the coast from Cape Delgado to Cape Gardafui, including the ports of Monigallow, Lundi, Quilobah, Melinda, Lamoco, Brava, Maga- dino, &c. and he has probably an establishment at Remba, Socotra, &c. Only a small part of this immense territory is garrisoned by his troops; but all, or nearly all, of it is tributary to him. He rules with patriarchal and despotic sway, his manners just and liberal spirit. His government is strict and to Europeans comes near to that of the English. He walks the streets of Muscat at any hour of the night unmolested. Goods are piled up in the streets exposed night and day, and pilfering is never attempted.

The Imam derives his revenue, which is more than adequate to his expenditure, chiefly from commerce, in which he employs a great number of merchant vessels; from import duties on foreign merchandise; and from tribute money or the equivalent presents made him by princes under his sway. His naval force, more efficient than that of all the native empires and princes from the Cape of Good Hope to Japan, numbered in 1857 15 vessels, carrying from 6 to 74 guns; 60 barges (one-masted vessels of 200 to 300 tons), carrying 20 to 300 tons; 500 boats (10 to 100 tons); 5000 to 8000 tons), carrying 4 to 6 guns. The number of vessels belonging to the port of Muscat at the same time, was estimated at 8000 or all sizes, a very large proportion of these being small craft. He has intelligent officers and abundance of sailors; but he keeps only a small number of regular troops, as he can have any number of Bedouins whenever he wants them, merely for the clothing and maintenance. His naval force however is sufficient to enable him to maintain his independence against all the infatuated pretensions over all the territories he claims as his own.

MUSCIDÆ. The House-Fly (Musca domestica) is very common in houses in England. Its favourite position is the window, on the panes of which it may be constantly seen walking. The possession of walking upon smooth upright surfaces has in consequence been a frequent theme of conjecture; and of not a small amount of observation. Dr. Derham, in his 'Physico-Theology' speaking on this subject, says that flies have four legs to hold them upright on the walls and ceilings, and other smooth bodies by means of the pressure of the atmosphere, after the manner as I have seen boys carry heavy stones with only a wet piece of leather clapped on the top as a stone.

This opinion, which has been entertained by the majority of entomologists of the present day, has acquired additional weight by the elaborate investigations of Sir Everard Home, undertaken at the suggestion of Sir Joseph Banks, with the assistance of Mr. Blackwall, and published in the Philosophical Transactions for 1816. The suckers, of which several kinds of flies possess three to each foot, are attached beneath the base of the claws, and are of an oval shape and membranous texture, being composed of two or more membranes, are composed; they had been seen under concave surface covered with down, or hairs. In order to cause the alleged vacuum, these suckers are extended; but when the fly wishes to raise its legs they are brought together, and folded up as it were between the toes. Messrs. Kirby and Spence have likewise adopted this opinion, considering it as "proved most satisfactorily." Other authors of no mean repute have however entertained a different opinion, and have entirely rejected the idea of a vacuum, and of the existence of such objects as suckers as palms, or soles, beset underneath with smallistles, or tenters, like the cone-teeth of a card for working wool, which he conceives gives them a strong hold upon objects having irregular or yielding surfaces; and he imagines that these tenters, or teeth, are perforated, penetrable by the points of these bristles. The same opinion is also given by Shaw in his Nature Displayed; and more recently, Mr. Blackwall has considered that the motions of the foot are to be accounted for by mechanical principles alone; thus, upon inspecting the structure of the parts of the suckers, it was immediately perceived that the functions ascribed to them by Dr. Derham and Sir E. Home is quite incompatible with their organisation. Minute hairs, very closely set, are found downwards, and crisscross the inferior surface of the expanded membranes, imperceptibly denominated suckers, with which the terminal joint of the foot of flies is provided, that it cannot possibly be brought into contact with the object on which those insects move, by any muscular force they are capable of exerting. The production of a vacuum between each membrane and the place of its position is therefore clearly impracticable, unless the numerous hairs on the under side of these organs individually exerted, and the effect produced an aggregate force necessary in order to be anything in their mechanism which in the slightest degree counterbalances such an hypothesis. When highly magnified, their extremities, it is true, are seen to be somewhat enlarged; but when they are viewed in action or in repose, they are an aggregate more at all than that of a vacuum." Moreover, on enclosing a House-Fly in the receiver of an air-pump, it was demonstrated to the entire satisfaction of several intelligent gentlemen present that the fly, while it retains its vital powers unimpaired, can only traverse the upright sides, but even the interior of the digits of an exhausted receiver; and that the cause of its relieving its hold, and ultimately falling from the station it occupied, was a diminution of muscular force, attributable to impeded respiration. Hence Mr. Blackwall is induced to believe that insects are enabled to take hold of any roughness or irregularity of surface, by means of the fine hairs composing the brushes, the most carefully polished glasses not being found competent to prevent the entrance of a drop of air, sufficient to enable a fly to proceed under a powerful effect with a powerful lens. A still different opinion has been maintained by other authors upon this subject, who, setting aside all idea of a vacuum, have conjectured that the suckers, as they have been termed, contain a glistening secretion, capable of adhering to well-cleaned glass; that these glandular substances are then excreted, and that these de la Pluche states that when the fly marches over any polished body, on which neither her claws nor her points can fasten, she sometimes compresses her spine, and causes it to evacuate a fluid, which fixes her in such a manner as to prevent her from moving without diminishing very perceptibly her progress. "But it is much more probable," he adds, "that the sponges correspond with the fleshly bulbs which accompany the claws of dogs and cats, and that they enable the animal to walk upright, without aid of legs, if the animal is to preserve its balance by the adhesion of the sensory of its claws, whose pointed extremities would soon be impaired without this prevention." Notwithstanding the
ridicule which has been thrown upon this opinion in a recent entomological work, it appears, from still more recent investigations, to be not unfounded. Thus, in general, the foot of the fly is described as being composed of two hooks and two flaps, or hollow cups, which act as suckers. Rymer Jones, in his 'General Outlines of the Animal Kingdom,' 1841, says—"The House-Fly is furnished with very minute hairs by his body, they are seen to be covered with innumerable hairs of the most delicate; these flaps, or suckers, as they might be termed, adhere, &c.'

The structure of the foot of the fly has recently been examined in a manner which, he says—'The flap varies in form in different species, from an irregular circle to that of an irregular triangle; and viewing it from one side, it is somewhat thicker at the base (near its attachment), the upper surface being perhaps somewhat convex, but perfectly flat as a whole, when applied to the surface of that form. It appeared to be composed of an upper and under layer of areolar tissue, or something similar to it, between which a bundle of tubes, along with the fasciculus of a large muscle passes; these are placed at its base, and (sometimes protected by a coat of mail,) formed by long scales enveloping each other as a Venetian blind, or in alternate ones, as the scales of a fish, &c., but more frequently wanting) expand in a radiated form, each tube, as it passes along with its fellows, sends off from the base extremities, the best for making observations, (it does not appear to be able to give out this secretion, although it can still attach itself; indeed this fluid is not essential for that purpose: when it is secreted, it is deposited on the glass with great regularity. I have sometimes seen the legs, when applied to a glass, covered with a great number of sucking cups, two or three being larger than the rest, but they form collectively a wonderful instrument of adhesion.'

"Quarterly Journal of Microscopical Science.

MUSCLE, MUSCULAR TISSUE. [Muscles, Organism, S. 1.]

MUSK-BEETLE. [Cerambycidae.]

MUSK-ORCHIS. [Himantodes, S. 2.]

MUSK-OX. [Ox.]

MUSK-ROOT, the root of a plant brought to this country from Russia and Persia, and known also by the name of Sumbul. This root exudes a powerful smell of musk, and has been used in medicine as a substitute for that substance. The plant yielding it is not known, but the root has the appearance of belonging to the natural order Umbelliferae. Its tissues are full of starch.

MYCTEOCHARUS. [Cutleridae.]

MYDROIDES. [Cutleridae.]

MYDROPHORUS. [Convolvulaceae.]

MYOPTERIS. [Chiropteridae.]

MYOSURUS (from μυς, a mouse, and συρ, a tail, the seed being seated on a long receptacle \( \hat{\} \) which looks exactly like the tail of a mouse,) a genus, which, under the natural order Ranunculaceae. It has a calyx of 6 sepals, prolonged into a spire at the base; the petals 6, with a filiform tubular claw; the capsules closely imbricated upon a long filiform receptacle, not bearing; the seeds of the radicle superior. The only species of this genus is \( \text{M. minutus}, \) which has a simple leafless single-flowered stem 2 to 5 inches high. It has a very long receptacle, numerous carpels, and linear leaves. It grows in damp places and in fields. It is a native of Europe and America. The American plant has been described as \( \text{M. Shortii}, \) but there is every reason to believe it is the same as the British and other European plants.

MYOTJTH. [Mammalia.]

MYRIAPODA, an order of Invertebrate Animals belonging to the class Articulata. This order is represented by such species as the Centipede and Gally-Worm. They may be regarded as an intermediate form between the lower and higher classes of the Arthropoda, because they agree with the Annelid forms in the longitudinal extension of their trunk, in the similarity of the segments from one end of the body to the other, and in their cylindrical form. On the other hand, they possess more complete eyes than any of the Verriform tribes, and their radicles, or legs, as parts of their organisation are more nearly allied to Insects. Their covering is firm, and of a horny character.

The division into segments is very distinct, a flexible membrane being interposed between each pair of rings or plates. The legs and other appendages are in the same kind of integument, and their joints are formed in the same manner as those of the body. We find in this class however two distinct types of conformation, of which one approximates most nearly to the Verriform tribes, and the other to that of the higher Articulata; in the former of which the Tulus (Gally-Worm) may be taken as an example. The body is generally cylindrical, or nearly so; the number of segments is considerable, and most of them bear two pairs of thread-like legs on their posterior part, and sometimes amounts to 160 pairs. The legs are very imperfectly developed, being scarcely large or strong enough to sustain the weight of the body, and their articulations being so indistinct that it is impossible to distinguish a pair from their assistance, like a serpent or a worm, than to use them as its proper instruments of locomotion. This kind of movement is facilitated in some species by the incomplete inclosure of the body in the consolidated integument, for this merely forms plates above and below, which are connected at the sides by soft membrane; so that the trunk can be easily placed in any direction. When at rest the body is rolled up in a spiral form; so that the legs, concealed in the concavity of Articulated, are the only visible parts of the body. The animals do not move with rapidity, as they chiefly discomposing organic matter. In the higher division, on the other hand, of which the Scolopendra (Centipede) may be taken as the type, the body is flattened, and each segment is completely inclosed in its horny envelope; the number of segments is not very great, never exceeding 22, and being sometimes as low as 12; and each segment bears a pair of well-developed legs, on which these animals can run with considerable rapidity. Still their bodies are possessed of considerable strength, and are enabled to pass with ease by their way with facility through very narrow and tortuous passages, in search of the insects, &c., which constitute their food. In both orders, the first segment, or head, is furnished with numerous appendages in each side; a pair of jointed antennae; the mouth is adapted for mastication, being furnished with a pair of powerful cutting jaws; and it is also provided, in the Centipede and its allies, with a pair of appendages, formed by a metamorphosis of the legs of the first segment of the body, which are adapted not merely to hold and to tear prey, but to convey poison into the wounds thus made, this poison being ejected through a minute aperture near their points. (Carpenter.)

The alimentary canal is mostly divided into gullet, stomach, and intestine. The stomach usually presents distinct muscular walls. The circulatory organs consist of a dorsal vessel, which propels a current of blood from behind forwards, which is distributed to the body and respiratory organs. In the higher forms respiration is effected by means of trachea, which convey air into the interior of the body as in Insects. The nervous system is arranged in a double series of ganglia, as in most of the Articulated Tribes. They possess cephalic ganglia, which unite above the osphagus, and form a series of rings, which are continued backwards into the eyes and antenna. In many parts of the double series of cords the ganglia of each side unite. The muscular appendages is very complicated, consisting of a series of distinct muscles for each of the appendages. The sexes are separate. The embryo at the period of hatching consists of but few segments, but these increase in number till it is fully grown by the subdivision of the, at first, solid segment. The first number of segments is eight or nine, and they go on increasing in number till they are thirty and seventy. The larva has no legs, these organs making their appearance later.
appearance after the first month. During their growth these
animals have considerable power of regenerating lost por-
tions of their body as the legs and antennae, but this power is
lost when they cease to develop.

Mr. Newport divides the Myriapoda into two orders—
Chilopoda and Chilognatha. [T. W. and C. Castelnau.] The
following synopsis of the genera of these two orders is
drawn up from the list of the specimens of Myriapoda in
the collection of the British Museum (1844):

Order I. Chilopoda.
Family 1. Cermatidae.
1. Cermatius, Illiger. 9 species.

Family 2. Lithobiidae.
1. Lithobius, Leach. 9 species.
2. Henicops, Newport. 1 species.

Family 3. Scolopendridae.

penters' Principles of Comparative Physiology.)

MYRISTICUM. [Chemistry, S. 2.]
MYRISTIC ACID. [Chemistry, S. 2.]

MYRICA, a genus of Insects belonging to the order
Hemiptera, and the family Formicidae. It is one of the
genera formed out of the Linnean genus Formica. Unlike
that genus, however, it possesses a sting. The peduncle of
the abdomen is composed of two knots, the antennae are
exposed; the maxillary palpi are long and 6-jointed, and the
trochanters are rudimentary. M. rubra is a common British species.

MYRORHANNIS. This is a name applied to almond-like
kernels of a nut or dried fruit looking like a plum, of which
there are several sorts known in this country. They are the
produce of various species of Myrornissae, as to T. Belonii,
T. Chebula, T. citrina, and T. angustifolia. They vary from
the size of olives to that of gall-nuts, and have a rough,
bitter, and unpleasant taste. Many of the trees of this tribe,
which are all natives of the tropical regions of Asia, Africa,
and America, are esteemed for tanning, and some for dyeing.
They are highly valued by dyers, creating, when mixed with
alum, a durable dark-brown yellow. Myrornissae fetch in
the Bombay market 8r. to 26r. the Surat candy of 831 lbs.
The bark and leaves of T. Calappa yield a black pigment,
which with Indian ink is made; the seeds are eaten like
almonds. A milky juice is said to flow from T. angustifolia,
which, when dried, is fragrant, and, resembling Benzoin, is
used as a kind of incense in the Catholic churches in the
Mediterranean. The fruit of T. Belonii, and of T. Chebula,
both useful timber-trees, indigenous to the East Indies, are
used medicinally as a tonic and astringent. One hundred
and seventeen cwt. of Myrornissae were shipped from
Ceylon in 1842.

The annual imports of Myrornissae into Hull, amount to
about 1600 cwt. The quantity which arrived at Liverpool
was 168 tons in 1849 and 861 tons in 1850; 27,213 bags in
1851, and 19,949 bags in 1852; they came from Calcutta
and Bombay, and are also used for dyeing yellow and black.
The price in January 1853 was 6s. 12d. per cwt. The aver-
age annual imports into the United Kingdom may be
taken at 1200 tons.

Myrornissae is also the English name given by Lindley to
the natural order Convolvulaceae, which yield many fruits.
(Symonds, Commercial Products of the Vegetable Kingdom.)
NAP 445

protruding their bodies. Some have black spots on their heads, which have been regarded as eyes. To this family belong a large number of little-studied forms of very minute fresh-water worms. The smaller ones are sometimes called Viburmes, of which the very common Viburmes subterraneus of the amateur microscopist is an example. It also appears to embrace the Sylorina of Lamark, the Proto of Oken, and the Crininae of Saviagey.

The soil is composed of Carbon and Hydrogen, frequently found in the neighbourhood of coal-deposits, and in other parts of the earth. It contains 82\% of carbon and 14\% of Hydrogen. It is a limpid or yellowish fluid, lighter than water, and hence called Mineral Oil. Its specific gravity is the same as that of the army. The substance called Petroleum on exposure to air. It may be obtained from Petroleum by heat, which causes it to pass off in vapour.

Naphtha issues in large quantities from the coast of Persia and the Birmian Empire. At Raungon, on one of the branches of the river Iravadd, there are upwards of 500 naphtha and petroleum wells, which afford annually 419,000,000 heads. In the peninsula of Acheron, on the western shore of the Canus, is a well of oil, known as the core of the Cole, and is collected by sinking pits several yards in depth, into which the naphtha flows. There is an abundant spring near Amiana, in the Duchy of Parma. Mr. Dana says that in the United States it was formerly collected for sale by the Syndicate, on the lakes, and on the coast. The naphtha is used by the army as a smoking mixture. It is an excellent medicine, and is found to be a good stimulant in some chronic diseases. It has been externally applied as a lotion in cutaneous affections. It is sometimes substituted for drying oil in making paint. It is also employed for preserving the metals of the alkalis potash, soda, and sodium, which cannot be kept in contact with any substance containing oxygen.

The Raunoon petroleum contains the compound Paraffine. This substance has also been obtained pure in a liquid form from the coal-pits of Derbyshire. It is used for the purpose of diminishing the friction of machinery as a substitute for sperm-oil. It is now obtained artificially from coal, and also in a solid form, from which candles are made.

[Dana, Manual of Mineralogy ; Gregory, Handbook of Organisation.

NAPHTHALEINE. [Chemistry, S. E.]

NAPIER, SIR CHARLES JAMES, G.C.B., was the eldest son of Colonel the Hon. O. Napier, comptroller of accounts in India, by the Lady Sarah Lennox, daughter of Charles, Duke of Richmond, on the Girn, on the 10th of August, 1782. Having received his early education under his father in Ireland, he obtained his first commission as ensign in the 22nd foot before he had completed his twelfth year, and first saw active service during the Irish rebellion of 1798, and again in the insurrection of 1803. In 1805, having obtained his company, he joined the British forces in Spain, and commanded the 55th regiment of foot during the terrible retreat on Corunna under Sir John Moore; he was mortally wounded, and was taken prisoner. Being allowed to go to England on parole, he found his friends actually in mourning for him as dead, and administering his effects; and he employed his period of captivity in writing on colonia, colonisation, and military history, and an essay on the state of Ireland.

In 1809 he again joined the British army in the Peninsula as a volunteer. He had two horses shot under him in the desperate conflicts on the banks of the river Corunna, and the Duke of Wellington had him by chance on the hard-fought battle of Fuentes de Ochoa, in the second siege of Badajoz, as well as in a considerable number of lesser skirmishes. In 1813 we find him serving in a floating expedition on the coast of the United States, and as well as in the North, and many of theGanges N. A. P. 1981 of 1197, and frequent descents upon the coast. He returned to Europe a few days too late to be present at the battle of Waterloo, though he took part in the storming of Cambry, and accompanied the British army to Paris.

Not long after this, while stationed on the Ionian islands, he was appointed governor of Cephalonia. Here his administrative powers were freely developed; and the success of his government is proved by the fact that to the day of his death the Cephalonians called him their "good friend," and paid him an annual tribute of the produce of their vines. While holding this post he joined Lord Byron in a scheme for the deliverance of Greece. He was shortly afterwards superseded—an event which he regarded, whether rightly or wrongly, as an injury inflicted on his merits.

After a short command of the military district of the north of England, in 1838 and 1839, Sir Charles Napier, now a major-general, was ordered in 1841 to take command of a force in the Crimea. This was the culminating point of his career. At Bombay he attracted attention by his energetic plans of military reform, to which he continued to devote himself until the appointment of Lord Ellenborough to the governor-generalship of India. At his suggestion Sir Charles Napier drew out the plan of an Afghan Campaign. Situde at this time was in a very disordered condition, and the British influence and prestige had been much impaired by the disasters in Kabul. The Ameers of Sind were perfectly as they were before, and, as they had by no means, to subdue them by open attack. For the first time they were eminently successful. He blew up the fortress of Eumam Ghur, which was always deemed impregnable. Having accomplished this exploit, which was characterised by the execution of the late Governor-General, he made himself acquainted with the extraordinary and extraordinary forces of all military feats, he pressed on, and with a very inferior force in point of numbers routed the Ameer at Meenane, February 17, 1845. In a few days the army took possession of Hyderabad, and outflanking the Persian force of the side was driven from the field with prodigious slaughter. Having now become master of the fair territory of Sind, Sir Charles Napier set vigorously to work to improve its condition. He re-organised the native society, re-distributed the collectorate of the native land, and set the tenure of land on a more just and judicious footing. While in the midst of carrying out these reforms Lord Ellenborough was recalled by the East India Company, and Sir Charles Napier felt that he had lost his best friend and supporter. His Indian services are thus summed up in the words of his brother Sir William Napier, in his Narrative of the Administration of Scinde:—"Two years only elapsed since he quitted Suckur to make war on the Ameer, and in that time he had made the march to Eumam Ghur in the desert sun, gained two great battles, reduced four large and many small fortresses, captured six sovereign princes, and subdued a great kingdom. He created and put into operation a new method of administration to all its branches, conciliated the affection of the different races which inhabited Scinde, had seized all the points of an intricate foreign policy, commenced a number of military and other well-considered public works, and planned still others connected to the sea, but having also a prospective utility of aim." And all these works he performed in spite of a press of correspondence, long journeys on camel and horseback beneath a tropical sun, and under frequent and severe attacks of illness, at the age of sixty-three, and in spite of every mortification that malice and intrigue could devise against him. Unwilling to leave Sind without some permanent proof of his ascendancy over the popular mind, and the consciousness of having contributed materially to the prosperity and happiness of the people, he contrived to change the feudal system of land-tenure for that of landlord and tenant, considering that such was the best plan of forming loyal subjects by raising a class of farmers and small landholders attached to the government by ties of a personal and pecuniary interest. In 1847 Sir Charles Napier returned home, and met with an enthusiastic reception; but ever ready at the call of duty, he re-engaged for India in March 1849, at the suggestion of Lord Palmerston, and as he had continued to hold a mind to work forthwith to carry out a system of military reform, his immediate object being to school the luxury and extravagance of the British officers into a simple and severe mode of living. In this work he was partially successful.
He returned to England in 1850, but his health and spirits were fast failing, and the last time that he appeared in public was on the occasion of the funeral of his friend and patron, the Duke of Wellington, in November 1862. He died of a gradual decline at Oaklands, his seat, near Portsmouth, on the 29th of August, 1853, like a gallant soldier, under the old colours of the 22nd regiment and other trophies of his European and Indian career, buried in the ground to which he had been attached to the gown chapel at Landport, near Portsmouth. Sir Charles Napier was twice married—in first, to Elizabeth, daughter of John Oakley, Esq., of Deal, Kent, by whom he had two children; and secondly, in 1834, to Frances, daughter of William Philips, Esq., and widow of Captain B. Alcock, B. N. A bronze statue of the conqueror of Sinds has been erected by subscription in Trafalgar-square.

NAPLES.—The continental territories of the kingdom of the Two Sicilies are divided into 15 provinces, the area, subdivisions, and population of which are given in the subjoined table. The provinces beyond the Favo are given under Sicily, & 2.

Population of Sicily at the Census of 1851: 2,091,880

Population of the kingdom of the Two Sicilies: 8,704,742

NARBERTH. [Pembrokeshire.]

NARCISSUS, a genus of Plants belonging to the class Euphorbe and the natural order Amaryllidaceae, among which it is known by its flowers and growing upon a scape, and having a cup at their mouth; the stamens, which are opposite the sepal being longer than the others. It consists of bulbous plants principally inhabiting the warmer parts of Europe.

N. pseudonarcissus, the Daffodil. Scape 2-edged striate; flowers nearly sessile in sheath; crown erect, nearly as long as segments of corolla; stamens equal. It is found in woods and meadows throughout Europe.

N. incompresis has the scape 2-edged. It is found in France and Italy and the coasts of the Mediterranean, and is naturalised in Great Britain.

B. Leaves nearly flat; flowers hypocrateriform.

N. calathina. Scape 2.4-flowered. A native of the Isles of Gleneagles and of Brittany.

N. chrysanthus. Scape 2.6-flowered. Mediterranean and France.

II. Scape 2-edged.

N. poeticus. Scape 1-flowered; petals white. It is found on open heathy fields in Norfolk and Kent, in Great Britain; it is also found in Austria and various parts of Italy.

b. Crown and petals white.

N. p. polyanthus. Scape slightly 2-edged, 8-20-flowered. It is found near Toulon and Nice, in stone places.

N. r. Scapo 6-10-flowered. It is a native of France.

N. unicolor. Scape 10-15-flowered. It is found at the base of Vesuvius.

C. Leaves convoluto-setaceous.

N. soriernus. Scape 1-flowered. It is found near Palermo, on open hills.

N. cantabricus. Scape 1-flowered. It is found in Italy. N. intermedius is probably a variety of this species.

The species, from their hardiness or gay colours, or sweet smell, have long been favourite objects of cultivation, especially the Daffodils, Jonquils, and Tazettas. A very full account of them will be found in the 'Amaryllidaceae' of the Honourable and Reverend William Herbert, p. 398, (Svo, London, 1837), who however divides the genus into six others, after the example of Salisbury and Haworth; but as these genera are not likely to be adopted by botanists, with the exception perhaps of the genus Corbabaria, no account need be given of them. With regard to Corbabaria, to which the name of Hoop-Petticoat Narcissus is given, and of which five supposed species are enumerated, the peculiar form of the flower and the delicate stamens of that plant may perhaps entitle it to be regarded as a peculiar genus; the species are pretty, all yellow flowered, with the single exception of C. cantabrica, a little plant with white flowers found on the mountains of Bisay and the Pyrenees, but now lost in Spain.

NATAL. The British colony on the south-east coast of Africa, is bounded S.W. by the river Umzincula (about 30 miles W. from the Umnzincula, the previous boundary), N.E. by the river Tugala, N.W. by the Drachenberg or Quatthama Mountains, and S.E. by the Indian Ocean. The colony lies between 29° 20' and 32° 50' S. lat., 29° 40' and 31° 25' E. long. The area is about 29,000 square miles. The white population in 1853 was 7029, the native population 112,988.

The Drachenberg or Quatthama Mountains form a broad range which runs nearly parallel with the coast, at a distance varying from 60 to 90 miles from the shore. The average height of the range may be estimated at 8000 or 9000 feet above the sea, and the summits are covered with snow at least 4 months in the year. On the north-west, or interior side, a table-land slopes gradually down almost from the summits of the mountains, exhibiting extensive plains, diversified by a few isolated mountain-groups and low ranges of hills. There is no pass in the whole range between 29° 20' and 31° S. lat. practicable for horses or wheel carriages, and there are very few for pedestrians. Coal occurs not far from the sources of the Tugala, and ironstone is frequently found. Copper has been discovered within 20 miles of Pietramaritzburg. In Natal the country gradually rises from the sea to the foot of the mountains. A few mountain groups occur, which are offsets from the Drachenberg range. The country is diversified with hill and dale.

The rivers are very numerous, and all flow eastward to the sea. Two of the largest are the Tugala and the Umzincula; they both rise in the Drachenberg Mountains. The Tugala receives several tributaries, of which the principal is the Tugala which forms a portion of the country to the north and the Bushman River; and it reaches the sea in 29° 16' S. lat., 31° 25' E. long. It has a bar at the
mound, and is not navigable. The Umzimkulu flows through a rugged and almost inaccessible country, and falls into the sea in 30° 30' S. lat., 29° 20' E. long.

Along the coast, in summer, the average temperature is about 74°F.; in winter about 62°F. Nearer the mountains the climate becomes colder. The rains generally commence in March, and end in September. Thunder-storms are of frequent occurrence, and are very violent. The climate, on the whole, is healthy.

The climate and soil have been found suitable for the cultivation of pumpkins, and it is doubtful if it can be cultivated profitably. Indigo, sugar, and coffee are cultivated, and it is expected that sugar and coffee will become articles of export. Tobacco, cotton, potatoes, pineapples, and pumpkins are raised in abundance. Cattle thrive well; but the climate does not appear to be suitable to the growth of wool. Horses are liable to sickness in the spring months, and many die. The soil is generally more fertile than in the Cape Colony, nor does it appear to suffer so much from droughts.

The elephant, which was formerly common in the colony, is now nearly driven away. The lion and leopard are still met with along the mountain ranges. Hyenas, jackals, wild dogs, ant-bears, and porcupines are numerous. The hippopotamus abounds in several of the rivers, and in the Tugela are numbers of small crocodiles. The larger antelopes are becoming scarce, but there are still many of the smaller ones. The vulture, which is regarded as a memorial of eternity. Several valuable timber-trees grow on the declivities of the mountains and in the mountain valleys.

The colony of Natal is divided into the districts of Pietermaritzburg, D'Urban, Umvoti, Imapana, Tugela, and Umzimkulu, and Natal. The principal town in the colony is Pietermaritzburg, founded by the Dutch boers in 1840, and containing about 3000 inhabitants. It is situated on an offset of the Drakensberg Mountains, in 32° 30' S. lat., 21° E. long., about 50 miles W.N.W. from Port Natal. It contains a barrack, ordnance stores, and Dutch, Episcopal, and Methodist places of worship. It is well supplied with water. D'Urban, the only port of the colony, is situated on the east side of the inlet called Port Natal, which is a bay completely landlocked, and affording good anchorage. The entrance is narrow, and is impeded by a bar, on which there is sometimes not more than two fathoms of water. The cape at the entrance of Port Natal is in 32° 58' S. lat., 21° 3' E. long. Verulam, Winterton, and Williamstown are the largest of the villages.

The white population of the colony is mostly composed of the original Dutch settlers who remained after the dispersion of the boers in 1842, and of the immigrants who have since arrived from Great Britain. The population, consisting mostly of Tulars, is an intelligent and docile people, and make excellent servants. They are scattered in kraals along the banks of the rivers, and round the mission stations along the coast and western boundary. The British colonial court at the capital, Natal, has the same capacities as those of the other courts. It is administered by the High Commissioner, who is regarded as their protector and chief. British, American, and Norwegian missionary societies have mission stations in the colony.

Natal has a lieutenant-governor, who is assisted by an attorney-general and an auditor-general, a collector of customs, a surveyor-general, a crown prosecutor, and a government secretary, who form a legislative and executive council. The revenue in 1854 amounted to 28,454 13s.; the expenditure in 1854 amounted to 28,454 13s.; the balance of the public funds for the year ending 31st August, 1855, amounted to 41,415 1s. A bishopric of Natal was created in 1855, and there are episcopal missionaries at Pietermaritzburg and D'Urban.

The colony of Natal owes its origin to the Dutch boers (farmers), who in the year 1638 emigrated northward beyond the Zooloo river, and became independent of the Cape Colony. They settled themselves in small communities, with their families and cattle, in different parts of the unoccupied territory. These emigrants in 1838 employed their commandant, Pieter Retief, to enter into a treaty with Dingaan, the chief of the Zooloo. Retief was afterwards attacked by Dingaan's followers, and 70 or 80 farmers, and their families and attendants, who visited Dingaan at his place of residence, preparatory to forming their intended establishment in the vicinity of Port Natal. They were received by the Zooloo chief and his warriors with every demonstration of kindness, but were treacherously surrounded and slain in the midst of a professedly friendly festivity. The farmers scattered over the country were next attacked successively, and upwards of 600 men, women, and children were killed, besides those who had been previously massacred at Dingaan's residence. The great body of emigrants, who still remained behind the Drakensberg Mountains, sent off expeditions after expedition to throw open the heights of Natal, and to an attack against Dingaan. The treaty made at Drachenberg, in February 1838, succeeded in putting him to flight. The Dutch farmers then removed to Port Natal, where, in December 1839, they hoisted the tricolor flag, and proclaimed an independent republic, with Andreas Wilhelm Pretorius for president. The British government refused to recognize this independence, and Sir George Napier, then governor of the Cape Colony, sent some troops to take possession of Port Natal. They entrenched themselves, and maintained their position till the arrival of reinforcements by sea, in June 1842, when the Dutch were compelled to submit. By proclamation dated August 21, 1845, the colony of Natal was established by the British government.

NATURALIZATION. A simple and inexpensive method of obtaining naturalization has been provided by the statute 7 & 8 Vict. c. 60, which enables the Home Secretary to give a certificate entitled an alien, on his taking an oath of allegiance and fidelity, to all the capacities and rights of a British subject, except those of sitting in Parliament, or holding office, or being a councillor, or having a majority of the votes in elections. Persons, however, who are considered to be aliens temporary character only as a subject; that is, the alien cannot, on returning to his own country, claim the protection of the British flag, as if he were a natural-born subject. This statute also enables any to hold every species of personal property, except chattels real; and every resident alien may hold lands or houses for residence, trade, business, or manufacture, for a term not exceeding twenty years; this occupation not, however, conferring any right to vote for a representative in Parliament.

The statute enables all persons born abroad of a mother who is a natural-born subject, to take any real or personal estate by devise or bequest, or by gift, or purchase, or succession, and it enforces de facto any alien woman who marries a British subject, in consequence of which, the notorious Mrs. Manning when indicted with her husband for murder, was held not entitled to make a indictment.
him there; but his health was still weak, and when in 1797 his friend Langara became minister of marine he provided Navarrete (now risen to the rank of captain in the navy) with a post in his office at Madrid. His life after this appears to have been as undisturbed by violent changes as a life can be in which one could see the whole set of the war of independence he refused to accept office under the French, and he removed to Seville, but he took no active share in the war. He was re-instanted in office as soon as Ferdinand returned, and for many years continued to be the historian of Spain, the owning power of the Admixture, although the title he bore was that of chief of the Hydrographic department, to which he was appointed in 1823. In the midst of his official duties his zeal for literature and science was not left behind, and he filled volumes, though he never showed them to any but his most intimate friends. As a member of the Spanish Academy, he proposed, about 1815, the new system of orthography which was adopted for its Dictionary, and has been followed by many of the Spanish writers. As secretary of the Academia of San Fernando, which is that of the Fine Arts, he was always at his post, and to their 'Transactions,' and those of the Academy of History, he was a contributor of valuable papers. He was also the author of numerous works, some of which were written from the information they contain. He held his offices and also a distinguished place in the literate society of Madrid through several revolutions; and in 1834, when the Estatal Royal first appeared, he was appointed a member of the French academy, and he was one of the first created. He died at Madrid, on the 8th of October 1844, at the age of seventy-eight.

The great work of Navarrete is the 'Colección de los Viajes y Descubrimientos que hicieron por Mar los Españoles durante los siglos XV, XVI, XVII y XVIII,' ('The collection of voyages and maritime discoveries made by the Spaniards since the close of the 15th century'). The work was to consist of seven quarto volumes: the first and second were published in 1809, the third in 1819, the fourth and fifth in 1837, the sixth and seventh, chiefly consisting of documents relating to Columbus, have not yet appeared in print, but the materials for them were left by Navarrete at his death, arranged for publication and only awaiting the introductions and notes he intended to add to them. The book is described by Humboldt as "one of the most important historical monuments of modern times." Washington Irving, who went to Madrid expressly for the purpose of translating it, afterwards changed his intention, and, in order to save the new matter which it supplied to the 'Lives of Columbus,' in which in fact little belongs to Irving, except the style. This mode of dealing with the materials was perhaps the best that could have been adopted under the circumstances. A French translation of Navarrete's work was commenced never advanced beyond a few volumes. Navarrete was a man who let no day go by without searching into something, who habitually read with a pen in his hand, who had an excellent memory for names and dates, and other small facts, of all kinds, and a talent for combining their results; but he lacked the power of condensation; he was not the man to write a European classic; his prejudice as a Spaniard of the old school influenced not only his writings, but in its absolute theory interhaled with his dignity as an historian. Perhaps he did himself an injury by the learning with which he loaded his volumes. In his 'Colección' the number of new documents brought forward in the first two volumes, is said to have been five hundred, and six hundred in the third, which is certainly not in every large library, and necessary to be consulted by every inquirer into the subject of which it treats, it is little read and is mainly known as a mine for others to dig in. One of the most interesting values of the Hakluyt Society, Mr. Major's letters of Columbus, is for the most part taken from it; but there are few other documents in the collection of such surpassing interest as these.

The other great work with which Navarrete was connected was the collection 'Documentos de la Historia de España,' or 'Collection of Unpublished Documents for the History of Spain,' commenced by him in 1842 in conjunction with Don Miguel Salvá and Don Pedro Sainz de Baranda. The work was published in seven volumes, and, as a matter of interest, the editor of the society which is the most interesting value of the Hakluyt the number of manuscripts which he has added to the collection is one of the most important now publishing in Europe, and is, like Navarrete's previous one, indispensable in every large library. It has been frequently laid under contribution by English and American writers; in particular by Mr. Helps, Mr. Prescott, and others from the United States.

Among Navarrete's other works is the most copious life of Cervantes yet written, originally prefixed to a new edition of 'Don Quixote,' and afterwards separately published in 1818. The work contains a very complete collection of letters. This collection is one of the most important now publishing in Europe, and is, like Navarrete's previous one, indispensable in every large library. It has been frequently laid under contribution by English and American writers; in particular by Mr. Helps, Mr. Prescott, and others from the United States.

The other works of Navarrete are the most copious life of Cervantes yet written, originally prefixed to a new edition of 'Don Quixote,' and afterwards separately published in 1818. The work contains a very complete collection of letters. This collection is one of the most important now publishing in Europe, and is, like Navarrete's previous one, indispensable in every large library. It has been frequently laid under contribution by English and American writers; in particular by Mr. Helps, Mr. Prescott, and others from the United States.

to that of Götingen. After a short stay in Hamburg, in 1811, he transferred himself to the University of Heidelberg, where his remarkable theological attainments obtained him in 1818 the situation of Professor Extraordinary of Theology; and in the same year his reputation occasioned him to be called to a similar office in the University of Berlin. From that time his whole life was devoted to the advancement of Christianity by his writings, which he continued to gain an ever-increasing influence of the world and of the students under his care. The earliest published work which established his reputation was 'The Emperor Julian and his Times,' which at once showed that in the face of the canon of the Church, he was the last to whose writings the General Councils ought to give weight.

It appeared in 1819; in 1825 was issued 'St. Bernard and his Times,' and others followed—on the principal Gnostic systems, on St. Chrysostom and the Eastern Church, on Tartillian and his writings, Memorable Occurrences from the History of Christianity and Christian Life,' between 1818 and 1829. These however were only the preparatory labours for his valuable work, 'Universal History of the Christian Religion and Church,' in 5 vols., issued successively between 1825 and 1845. The history of the Church, 'is, at once a speaking proof of the Divine power of Christianity; a school of Christian experience; a voice sounding through centuries for the edification, the instruction, and the warning of all who are willing to hear.' The development of the Christian Church is seen as the result of the spirit of his next work, 'Geschichte der Pfalzamtung und Leitung der Kirche durch die Apostel,' in 2 vols., published in 1852-33. In these works he has with great ability combated the neologism and rationalism so prevalent in Germany, to which he was ever a decided and uncompromising opponent. He has also combated the spirit of antichrist, which is so prevalent in the history of the Church. His smaller occasional writings were collected by himself, and published in 1859 under the title of 'Kleine Gelegenheitschriften,' for the benefit of the Bible Society of Berlin, of which he was always an earnest supporter. The 'Life of Christ,' 'History of Christianity,' 'History of the Planting of Christianity and of the Apostolic Church,' and other of his works have been translated into English, and form a part of Bohn's 'Ecclesiastical Library.'

The Missouri, as one of the United States of North America, established by Act of Congress 1854, occupies the tract of unclaimed country north of the Nebraska River up to 42° N. lat. It is bounded E. by the state of Iowa, from which it is divided by the Missouri River; N. by the North-West Territory of the United States; W. by the Oregon and Utah Territories; and S. by the Territory of Kansas. The area is 336,886 square miles. The population in 1856 was 10,716. This country and Kansas have hitherto been usually spoken of together (Kansas, S. 9), and the descriptions published have included both. Like Kansas, Nebraska has on the east, extending down to the valley of the Missouri, extensive tracts of prairie lands; on the west a broken and hilly country, rising into the mountainous tract of the Rocky Mountain range; while the centre is occupied by a broad apparently irreclaimable waste, forming the northern part of the Great American Desert, and the home of numerous wandering tribes of Indians. But Nebraska has a larger share than Kansas of this desert land, and in other parts it is believed a fertile soil existed.

The Missouri, as we have said, forms its eastern boundary, and the only actual settlements, so far as we know, yet made in this territory are along the Missouri River, which flows along this river quite up to the Rocky Mountains. The chief affluent of the Nebraska belonging to this Territory are the Loup Fork, Elkhorn, and Wood rivers.

The chief settlement yet formed is Council Bluffs on the Missouri, which is within this Territory, though previous to its organisation assigned to Iowa, under which state it will be found noticed. It is of considerable local importance as the last civilised resting place of the emigrant to the 'far West,' who has reached the Platte River and previous to entering upon what has hitherto been commonly known as the Indian country. Council Bluffs was established as a government Indian agency station. Bellevue, a little lower down the Missouri, is the only other civilised settlement in the Nebraska territory, with the exception of a military station for the surveillance of the Indians. The chief tribes of Indians in Nebraska are the Pawnees, Poncas, Omahas, Ottos, &c.; but we have no account of their numbers or condition.

The Act of Congress which erected Nebraska into a Territory, leaves it open to settlement by citizens of the United States, and to aliens who make the usual declaration of their intention to become citizens; and deors to the inhabitants the right to determine whether slavery shall be permitted to exist within the territory.

NECKAR-KREIS (Circle of the Neckar), a province in the north-west of the kingdom of Württemberg, is bounded N. and W. by the grand-duchy of Baden, E. by the circles of the Rhine and the Swabian, and S. by Baden on the Neckar, and is 57 miles in length from north to south; its breadth is about 36 miles; its area is 1735 square miles; and its population in 1852 was 601,064. The province is traversed by several ranges of mountains, high forest-clad hills, which rise in the western or north-western direction from the Rhine Alb, or Alps of Säbha, in the east of the kingdom. It takes its name from the river Neckar, which, rising on the Baden frontier in the south of the Schwarzwalz, runs in a general northern direction, and is crossed by the river Rhine. Whence it flows northerly past Heilbronn, below which it turns to the north-west, crosses the territory of Baden till it reaches that of Hesse-Darmstadt; from this it forms the boundary to its entrance into the Rhine at Mannheim, after a course of about 170 miles.

Neckar receives in this province the Enz, the Kocher, the Jaxt, and a great number of small streams. It is navigable for small craft from Cannstadt. There are several lakes and mineral springs in the province. The valley of the Neckar, where other rivers is excessively rich and fertile. The chief products are wheat, hemp, wine, silk, and wood. Humped cattle, sheep, and horses of good breed are numerous. Railroads run from Stuttgart to Heilbronn, and from Stuttgart to Cannstadt. The Neckar (from Ulm a line runs east to Angsburg). From the former line a branch is constructed to join the great trunk line along the right bank of the Rhine at the Bruchsal station, between Carlsruhe and Heidelberg.

20 miles wide, formed by the Rio Grande del Norte, traversing it from north to south. The western range of the Rocky Mountains bears various names, as the Sierras de Anahuac, de los Mimbres, de los Orlucas, Mogollon, Madre, &c.; but the name now most commonly given to the greater part of it is the Sierra Madre. Many of the most northern summits of this range are covered with perpetual snow, and may be from 9000 to 13,000 feet above the sea. The southern point of the range is probably the summit of Picacho, which is a very high mountain, and the eastern range, which runs nearly parallel to the other, is known in the northern part as the Sierra Ocehres, and in the southern as the Sierra Sagrado, though the latter name is commonly applied to it throughout. These mountains rise very abruptly at their base, and their sharp, jagged, and crooked knobs variously disposed, with fertile valleys between them. Some of the southern summits of this ridge are also covered with perpetual snow, and the altitude appears to be on the whole somewhat greater than that of the western ridge. Fins generally grow on the higher mountains, oaks and occasionally oaks on the lower ones. The narrow tract bordering the Sierra Sagrado on the east is very elevated, and forms the western boundary of the extensive plain northwest of Texas. The rivers on the west, by which the mountain streams reach the plain, are often heavily timbered, and the soil appears to be fertile; but the intervening spaces have an arid soil, which is only covered with vegetation in the early part of the year.

The valley which lies between these mountain chains forms the district known as New Mexico while the country belonged to the Mexican republic. It is a very elevated tract, the northern part being more than 5000 feet, and the most southern, where it touches the Mexican boundary, 3800 feet more than the plain. Through it as mentioned above flows the Rio Grande del Norte. The surface, especially in the upper part, is greatly broken, and the soil throughout is dry and sandy; but where irrigation is generally very fertile. Rio Grande del Norte, the Rio Pecos, and the Rio Grande del Norte, and there these two crops are often obtained annually. This is the most productive and the only civilised part of the country; a large portion of it being occupied by the farms of the old settlers.

The country west of the Sierra Madre, forming nearly two fifths of the territory, is very much varied in surface. It is drained throughout by the Rio Colorado and its tributaries. The northern part is mountainous, and a large part of the eastern boundary is formed by rugged mountains. The interior is considerably diversified, its direct length from its source to its mouth in the Gulf of Mexico is about 1400 miles, but its course following its windings is full 2000 miles. Throughout New Mexico it is a rapid shallow stream, and has to some extent in its lower course a vast drainage area, and is navigable even by canoes, and though it is well fitted to supply mill-power, it is at present scarcely used except for irrigation. Its lower course is noticed under Mexico. The Rio Pecos is its only tributary of any consequence in this territory; but this stream, though it runs for a considerable distance through a longitudinal valley west of the Río Sagrado, has, owing to the arid nature of the soil, but little water. The Rio Colorado, which drains the western part of the territory, begins in the mountains of the southern part of the Rio Grande till it enters New Mexico, when it bears more to the west, and so continues till it quits the territory and opens into the Gulf of California. The Colorado is believed to be navigable for a great distance, but the country through which it passes is very mountainous and very barren. Several of its tributaries are also believed to be navigable for considerable distances. The most important tributary in New Mexico is the Rio Gila, which drains the great plains mentioned above. It rises in the most southern extremity of the western range of the Rocky Mountains, and after descending into the plain, where it is joined by the San Francisco, an affluent which rises much farther north, it flows through the plain nearly west-south-west to its confluence with the Rio Colorado, about 30° 40' W. lat. Here it appears to be worked on both its banks, but none appear to be of much consequence.

The other more important tributaries of the Colorado in this state are the Nabajos and the Yaquiola.

The mountains are composed of eruptive and metamorphic formations; the rocks enumerated consisting chiefly of granite, silex, haastt, porphyry, &c., but Silurian and Carboniferous strata also seem to have been recognised. New Mexico appears to be rich in minerals, and the silver-mines, gold and copper, which are the most noted. Gold has been found in many places. In the Santa Fe district the peasantery have long been accustomed to employ a good deal of their time in washing the river-sands for gold, and some gold-mines are worked. The Spaniards wrought several silver-mines, but none are now in operation. Copper is said to abound throughout the mountain districts, though only one or two mines are now worked. Iron is also abundant. Coal is said to have been found near the village of Jemez south-west of Santa Fe, and in other places. Gypsum occurs in various parts. On the high lands between the Rio Grande and Rio Pecos and in other places are extensive salt-lakes, or salinas, whence all the salt used in New Mexico is obtained.

The climate differs considerably, but is on the whole temperate; its great characteristic is its dryness. There is a rainy season, from July to October; but the rains are seldom heavy, and never of long continuance. The winters are long, especially in the north; but below Santa Fe the Colorado is rising from snows, and is generally much frozen. In the lower part of the valley of the Colorado the summer temperature occasionally rises to 100° Fahr., but the nights are generally cool. Epidemics are scarcely known. The grain products are confined to maize and wheat; mesquite is raised in the central valley; peas and beans, onions, red pepper, some fruit, and tobacco are also grown. Agriculture is everywhere in a most primitive state. Even in the central valley the chief dependence is on the raising of stock. Large numbers of horses, mules, cattle, sheep are reared, there being everywhere extensive pastures; but comparatively little attention has been yet paid to the improvement of the breeds, which are generally small and inferior.

The almost the only manufactures are those for which the natives have long been celebrated—namely, those of coarse and fancy blankets, in great request for the favourite national garment called the 'serape,' and the checked woolen- stuff called the 'chmere.' Almost all the wood is cut for fuel, and there are no manufactures. Most of the imported articles are received by the Missouri overland route by caravans, by way of Independence to Santa Fe.

Of the 61,695 white inhabitants, about 58,600 are the descendants of the Spanish settlers, and all of them are Roman Catholics. The settlers from the older states and territories of the United States were only 761 in 1860. The natives appear to be an indolent but contented race, taking more of the character of their Indian than their Spanish ancestors. The more laborious work is assigned to the females; not only the household work, and a good deal of the field labour, falls to their lot; but the spinning of the blankets and woolen wares is chiefly done by them. Of the horses, mules, and cattle, the number is very numerous. They are chiefly what are called Ateuc races, similar to those described under American Antiquities, § 1. Several are found along the banks of the Colorado and the Grande rivers and their tributaries. The most celebrated are those known as Las Creole. It requires several years to gain confidence under American Antiquities, § 1, p. 98. Some of equal extent, called La Gran Quiviri, occur near the Salinas, between the Rio Grande and the Pecos, about 100 miles S.E. to the Coloma. But very few of these animals, are said to be portions of an aquaduct 10 miles long.

Divisions, Towns, &c.—New Mexico is divided into seven counties. Santa Fe is the political capital, and though there are several other towns, they have necessarily so small a population that they cannot be very considerable. Among them is Alburquerque, on the left bank of the Rio Grande, 76 miles S. from Santa Fe, which is the only one which requires to be mentioned. It is said to have formerly contained 6000 inhabitants, but it has now little trade or population.
SANTA FE, the capital, is situated about 20 miles E. from the Rio Grande, in a valley formed by N., E., W., and S. ranges of mountains, and at an elevation of 7047 feet above the level of the sea; population, 4846 in 1850. It is an old town, having been founded by the Spanish settlers in 1611, and consists of narrow irregular streets, with houses generally built of adobe. It is situated in a large level plain surrounded by mountains, and it contains two Roman Catholic churches, but no other public buildings of any note. The inhabitants are still nearly all of Spanish and Indian descent, but there are a few Americans, who have established two newspapers and a printing office. His government consists of an assembly of inhabitants, and the relation between these two functions long before the chemical changes by which they are accompanied were understood. In his papers also on the reproduction of limbs in articulate animals, the structure of the ovum in fishes, the development of the ovum in the same class of animals, will be found a series of researches bearing on all the modern progress of physiology.

WHILES it is as an anatomist and physiologist that Newport takes a first position, his minor works and papers claim for him a position of still higher estimation. He was diligent in his observations on the habits of insects, as is proved by his prize essay on the 'Habits and Economy of Athalia centrifolia, the Sawfly of the Turnip.' Besides this paper he published many others on the habits of insects.

In one of these papers he described a species of Parasites, and worked out their history in the most accurate and beautiful manner. This paper was published in the 'Transactions' of the Linnean Society, and was entitled, 'The Anatomy and Development of Calcicididae and 'Transdon,' compared with their special Economy and Instincts; with Descriptions of a new Genus and Species of Bee-Parasites.' As a systematic entomologist, he devoted his attention to the description and classification of the insects, and a series of researches in the British Museum were arranged, and the catalogue descriptive of them published by the authorities of that institution was drawn up by him.

Newport early joined the Entomological Society, and contributed many papers to its 'Transactions.' In 1844 he was elected president of this society, and in 1845 he was re-elected.

During the last few years of his life he devoted great attention to the development of the ova in various kinds of animals. He published two series of papers on the development of the embryo in the ova of the Amphibia, and at the time of his death was engaged in drawing up a third. It was in consequence of pursuing this subject that he met with his death. In the spring of 1845, being desirous of obtaining a complete series of the ovum, he exposed himself to the malaria of the ponds which these creatures inhabit, and on the 6th of April sunk under a fever thus contracted.

Although Newport became a member of the College of Surgeons in 1835, and was made an honorary fellow in 1843, he was too devoted to his scientific pursuits to follow his profession. But England has no positions to offer her men of science, and during the latter years of his life he maintained himself on a pension of £70 a year granted him by the government. Even the luxury of belonging to a scientific society has to be paid for, and out of his small pension Newport maintained his connection with the Royal and Linnean societies, of which he was so distinguished a member. But he was twice rewarded with the royal medal of the Royal Society, and was a member of the council of both the Linnean and Royal Societies. His works were highly appreciated by Continental and other scientific nations, and he was honorary member of several foreign societies. He was an amiable, retiring man, little known beyond the limited sphere of men who cultivate the sciences of comparative anatomy and physiology; but his name will become more widely known when his work is studied; the true value of his researches be more widely appreciated.

NEWSPAPERS. In the 'Penny Cyclopaedia,' vol. xvi., an account was given of newspapers down to 1838. Of the different kinds and numbers of newspapers which circulate in the different countries may have varied somewhat, but their character remains unchanged, except that in France they have been brought still more under government control.

In...
that country they are liable to an official warning for any
infraction of prescribed rules, and after a third warning the
publication is suspended.

In treating of the origin of the newspaper, we stated in
our previous article that the claims of 'The English
Mercuries,' which first appeared in the British Museum,
were forgeries, and that the forgery was perpetrated about
1766. The three numbers, which are marked 50, 51, and 54,
purporting to be part of a series, contain seven articles,
three of which are in print, and four in manuscript.

This series is known as the 'Trojan Horse,' and is
affected, while in the manuscript the spelling is modern,
with a number of corrections in a different hand-writing;
and the manuscript is written on a paper, with the watermark
of the royal arms and initials of "G.R." In 1850 Mr. Watts
made public the result of his further investigations, which
showed that the manuscript was in the hand-writing of
Philip Yorke, the second Earl of Hardwicke, and a few
of the corrections in that of Dr. Birch. Mr. Watts also
proves that the "Illustrated London News," the "Gazette of Paris," in 1831, are also unfounded, and that the
earliest specimen of this branch of literature belongs
"to Italy or to Germany." The claim of Germany is
strongest: at Angoulême and Vienne printed sheets containing
numbers of this "Troyan Horse" are to be seen.

Since the publication of the previous article, the abolition
of the advertisement duty in 1853 (16 & 17 Vict. cap. 33);
the total removal of the stamp duty in 1855, or at least
reduction in cost, for the purpose of paying the penny
postage, which gives the privilege of circulating by post
for fifteen days (16 & 19 Vict. cap. 23); and the introduc-
tion of machinery, by which from 10,000 to 15,000
copies can be produced in an hour; have united in
great numbers to the postal service, the newspapers of
the United Kingdom. In London there are now (April 1859)
published 11 morning newspapers instead of six. The
'Times,' which usually consists of 16 pages, or two sheets,
seems to be an optimal for the purpose of paying the penny
postage, price 4d.; the 'Morning Advertiser,' the 'Daily News,'
the 'Morning Chronicle,' the 'Morning Herald,' the 'Morning
Post,' and the 'Public Ledger,' each of 8 pages, and price 4d.;
the 'Standard' and the 'Daily Telegraph,' each of 8
pages, the 'Morning Star' and the 'Morning News,'
each of 4 pages, the last four published at 1d. each.

As there is now no record of the numbers printed, it is
impossible to give more than approximations; but it is known
that the 'Times' publishes daily from 60,000 to 65,000
copies, and the 'Morning Post,' which is using its own
printers to print 100,000, the general sale nearly approaching
that number. It is clear, indeed, that only a very large sale,
with numerous advertisements, for which the wide cir-
clerange, of the circulation of the occasions of advertisements
in the higher-priced newspapers to maintain themselves, particularly
as some of them, the 'Standard,' for example, do not rely on
the higher-priced morning papers for the more expensive arti-
cles of intelligence, such as the foreign and telegraphic com-
munications, reports in parliament, &c. Of evening papers there
are now eight, the 'Express,' the 'Globe,' the 'Evening
Herald,' the 'Evening Star,' the 'Sun,' the 'Shipping and
Mercantile Gazette,' the 'Shipping Advertiser,' and 'Lloyd's
List" are all weekly newspapers. In London, the 'Globe'
and the 'Public Ledger,' among the morning papers. Of the
others, the 'Globe,' the 'Sun,' the 'Shipping and Mercantile
Gazette,' are papers of 4 pages, price 4d. The 'Express'
and the 'Evening Herald,' are branches of the 'Daily News'
and the 'Morning Post,' and are in the British Museum.
The price 1d., is an evening edition of the 'Morning Star.' The
London Gazette" and the 'Patriot,' the organ of the In-
dependent and Baptist dissenters, are published twice a
week. The 'Evening News,' the 'Evening Journal,' the 'Ex-
change Mall,' the 'St. James's Chronicle,' 'Monet's Times,'
the 'Record," are published three times a week.
Weekly London papers there are altogether 111, but this includes
literary papers, such as the 'Atheneum,' the 'Literary
Gazette,' and 'The Literary Repository,' and many other
publications, such as the 'Solicitor's Journal,' the 'Builder,'
and the 'Pawbroker's Gazette'; but they are all essentially
newspapers, though not all political. One remarkable
feature is the existence of a considerable number of local
papers in London, the 'City Press,' the 'Clerkenwell News,'
the 'Islington Gazette,' the 'Islington Times,' the 'Holborn
Journal,' the 'Marylebone Mercury,' and several others.
These are chiefly papers devoted to local affairs and adver-
tisements, some of them selling a penny in price, and
some being published at a halfpenny. Some other
weekly newspapers are conducted with a large amount of literary
and political talent, and are of a higher price, such as the
'Examiner,' the 'Spectator,' the 'Saturday Review,' the
'London, Gazette,' the 'Leader,' 'The Times,' the 'House-
hold Words,' 'Chamber's Journal,' &c., which, as
not containing news, are not included among newspapers.

Of local newspapers published in England there are 411,
and in Wales 32. Many of these are daily papers,
which are mostly published in the smaller towns; but
Birmingham has two daily papers and Liverpool one
at that price. There are 131 newspapers published in Scot-
land, and the prices vary from a penny, of which price
the extreme is as low as 3d., and £1 being paid for the
London evening papers in Ireland there are 123 published, but only Belfast
and Dublin have any papers so low in price as a penny.

In the Isle of Man and the Channel Islands, there are pub-
lished 13 newspapers, at prices varying from a penny
to three-pence. In the Isle of Wight the price of
the paper named the price independent of the stamp, which in all
cases is charged for extra if a stamped paper is required.
As we have already mentioned it is perfectly impossible even
to attempt to give an estimate of the numbers of papers
which are printed in England, it cannot be done on the
paper which was issued in 1837 seven
one millions passed through the post-office, of which about
three-fourths bore the newspaper stamp, and the other
fouth an affixed postage stamp.

By the Act 18 and 19 Vict. cap. 27, any periodical pub-
lications, published containing thirty-one days of
which the print does not exceed the prescribed sup-
icipies, may claim to be stamped as a newspaper; but in each case
the title must be printed on the top of every page, with the
name of the printer, publisher, and, if printed, must be folded so as to
show the stamp denoting the duty. Newspapers to be sent
abroad by post may be registered at the General Post-office,
for which an annual fee of 4s. is charged, the year always
terminating on the 30th of June. It is not absolutely neces-
sary that the newspaper should be registered, but the English
Post-office then charges 2d. in addition to the foreign or colonial
postage. Before a newspaper can be published a notice must
be given at the Inland Revenue Office, Somerset House, or at
the District Stamp-office, where the form of a "declaration"
must be filled up and handed in. This document, in the in-
tended paper quoted literally; the place where it is to be
printed, giving the number of the house, the name of the
street and of the parish in which it is situated, and the
name and character of the occupation of the printer and publisher, is
like particulars respecting the place of publication if it
differs from the place of printing; the Christian and surnames
of the printers and publishers; the number of shares into
which the property is divided whenever the number, exclu-
sive of the printer and publisher, exceeds two; and the
Christian and surnames, residences, and occupations of every
proprietor, with the number of shares belonging to each
when exceeding two, exclusive of the printer and publisher. This
document, made by the printer and publisher, is signed by
the printers, or by two of the largest shareholders where
the number exceeds two, who must also furnish two respectable
householders as sureties against the publication of seditions,
blasphemous, or personal libels, to the amount of 400l. in
London and 300l. elsewhere. A newspaper adventure
these securities are given; subjects the proprietors to a penalty
of 20l. The paper when published must have across the
bottom of the last page or the last column, the names and
residences of the proprietor and publisher, the place of publi-
cation, the date and edition, the date of registration, and
the period of publication. A supplement must not be issued without the
paper itself; and a copy of the paper, which is paid for, must
be transmitted to the Stamp-office on the day of publication or
within three days, under the like penalty of 20l. for each
offence; but the penalties can only be sued for by the At-
torney-General or the Stamp-office.
The size and amount of stamp-duty for newspapers are defined as follows by the 16 and 17 Vict., cap. 65: Newspaper stamps are to be 1d. only, for a superfluous of print, on one side of the paper, not exceeding 2395 inches, whether published as a supplement or not; any supplement that with the original printed sheet of the newspaper can be exactly reduced to a sheet of one-halfpenny and any other supplement to a duly stamped newspaper not containing a superfluous on one side of more than 1146 inches of print to be subject to a stamp of one-halfpenny; and any two or more newspapers containing from 2396 inches to a duty of one halfpenny each, provided each be published on one sheet of paper only. Newspapers not stamped go by post at the book-post rate of a penny for 4 ounces, twopenny for 6 ounces, and then ascending by twopenny for every 4 ounces, and any number may be sent in one envelope open at the ends.

Newt (Listation punctata). [Salmandrele, p. 336.]

Newtown-Limavady. [Londonerly.]

Newtownards, County Down, Ireland, a market-town, and the seat of a Poor-Law Union, is situated near the head of Lough Strangford, in 54° 36' N, 6° 54' W. long., 124 miles E. from Belfast by the Belfast and County Down railway. The population in 1851 was 5676, besides 605 inmates of the workhouse. Newtownards Poor-Law Union comprises 16 electoral divisions, with an area of 55,841 acres, and a population in 1851 of 50,861. The town, pleasant and healthful in the midst of fields, is neat, regular, and well built. In the Market-square and principal streets are many good houses. The parish church is a handsome building, erected in 1817. There are chapels for Roman Catholics, Presbyterians, and Quakers, and a strong school. The old parish church, erected in 1632, a large building with a handsome spire, is now used as a court-house. There are a market-house, a bridewell, and a Union workhouse. The weaving and embroidery of muslin afford a considerable amount of employment. Quarter and petty sessions are held. Fairs are held on the second Saturday of every month, and on January 23rd, May 14th, and September 23rd. Near the centre of the town is the octagonal structure, with campanile on the top, forming the pedestal of a cross, erected in 1836. Newtownards was incorporated by letters Io, and returned two members to the Irish Parliament.

Nicae. [Canada, 6.]

Nicaea (Nicato), an ancient ruined city in Bithynia, in the north-west of Asia Minor, the site of which is marked by the Turkish village of Is-nik. It stood on the eastern shore of the Lake Ascania, and was built or restored by Antigonus, son of Philip, after whom it was called Antigonea. The foundation was subsequently enriched by Constantine, who married his wife, Nicaea, daughter of Polemaeus, king of Egypt. The city became early the seat of a Christian bishop. It was destroyed by an earthquake in the latter end of a.D. 325, but it was restored and the emperor Alexander II. erected a church. The church was restored by the Greek Nicephorus Melissenus and Theodore I. Solyman, took the city (1080), which was made their headquarters till 1097, when Godred de Bonillon, at the head of the Crusaders, took it after a siege of 36 days, and it was again united to the Greek empire. Two years after the establishment of the Latin empire in Constantinople (1204) Theodore Lascaris made Nicaea the Greek capital, which it continued to be till 1321, when in the reign of Manuel I. Komnenus it was crossed by Nicaea the year before), Constantinople was recovered by the Greeks. In 1333, after an obstinate and bloody siege, the Turks, under Orkan, again took Nicaea, which they made their capital. After the battle of Angora (June 30, 1402) it was taken and pillaged by the followers of Tamerlane. In 1428 it joined in a conspiracy to put Mestapha on the throne of his brother, Amurat II., whereupon the latter reduced the city to obedience, and had his brother and the chief conspirators strangled in the citadel. Sir Charles Fellows, who visited the site of Nicaea, says that the walls form a circuit of four miles. These walls are strengthened with towers. One part is built or repaired with materials of great elegance from an ancient temple; another part is built with brick; a third, and the most remarkable part, is of a later age, marked with the sign of a cross and ill-cut inscriptions, showing the repairs made in Christian times; the remaining parts are built of immense stones cut to fit into each other in the cyclostyled way. Four large majestic gateways with arched entrances still exist in an almost perfect state, but the inscriptions that once covered them have been nearly altogether effaced. Among the existing remains are many inscribed stones, copies of which are given in Sir Charles Fellow's 'Asia Minor;' ancient basilicas; a few edifices, which can be externally distinguished, and other ancient buildings, to prove the existence of an extremely good workmanship, and colossal, the stones being some nine and others fourteen feet in length." Ruins of mosques, baths, and houses are seen among the gardens and corn-fields near the town. In 1499 the town was besieged by the Turks, and changed into a small village of Is-nik, which stands in the centre of the ruins, there is a small church, used by the Greeks for their worship, with Mosaic floor and ceiling of the Byzantine age. Every fence, trough, or paving-stone in the village and its neighborhood is made of marble, and fragments of good sculpture are built into the houses. A Roman aqueduct still conveys water to the town from the neighboring mountains. In the lake, the waters of which are of transparent clearness, are the remains of an ancient landing-place.

In the history of the church Nicema is memorable as the place in which the first and seventh ecumenical or general councils were held. The first, held in 385 (June 19 to August 26), in presence of the emperor Constantine and presided over by Oysa, representative of Pope Sylvester, condemned the doctrines of Arius, maintained the divinity of Christ, and declared the consubstantiality of the Son of God with his Father to be an article of faith. The creed which was drawn up at this council is the Nicene creed, etc., is still true. This council also passed decrees for celebrating the festival of Easter on the same day throughout Christendom.

Nicaragua, Republic of, Central America, occupies the tibby and volcanic region extending from Salinas Bay to the Bay of Conchagua on the Pacific, and back to the rainy- belt. It may be taken generally as lying between 10° 45' and 14° 10' N. lat., 84° and 87° 40' W. long., and as bounded E. by the Mosquito Territory; N. by the republic of Honduras; W. by the Pacific Ocean; and S. by the republic of Costa Rica; but the eastern boundary is really undefined, Nicaragua refusing to acknowledge the right of the King of Mosquito to the tract lying along the Caribbean Sea. The area, consequently, comprises the entire country, which is really under the government of the republic does not probably exceed 35,000 square miles, but that claimed is of course much greater. The population may be about 200,000; the chief part of whom are ladinos, or mulattos, and native Indians.

The coast from Salinas Bay to the Gulf of Conchagua bears nearly north-west. It is throughout rocky, and has some harbours of much value. That which may just now be regarded as the most important, from its being the Pacific port for the Nicaragua route connecting the Atlantic and Pacific Oceans, is San Juan del Sar, north of Salinas Bay, which is formed by two promontories between 400 and 600 feet high, having an entrance above 3000 feet across. The harbour is small, but well sheltered, and in 1863 it was fitted up by the United States Government as a naval station. The site of the capitol is a mile from it is the nearly similar harbour of Nacacelo. Port Realejo, towards the northern end of the state, is also a very good and much larger harbour, and is that which, prior to the opening of the Nicaragua transit route, received most of the foreign vessels trading with the Pacific. There is a very narrow tract of tolerably level land along a good part of the coast.

Along the western side of the republic, at a few miles from the coast, is a ridge of low volcanos, the highest of which is 6150 feet on the southern end, and generally decreasing in altitude as we proceed northward: though one or two of the isolated peaks in the northern part are among the most elevated. It is supposed that the increase of these volcanos appear to stand alone, or to have scarcely anything in common with the rest, the only marked in its general line of direction. The highest summits appear to be Omotpec, which forms an island in Lake Nicaragua (3100 feet above the sea); Monomotomba, at the northern
extremity of Lake Managua, about the same height; Mombacho, between Lake Nicaragua and the Pacific (4500 feet); Nindiri, between Managua and Masaya; Felica; El Viejo, and one or two others. Several of these are active volcanoes.

Another mountain tract, a part of the mountain system of Honduras, extends along the northern part of the country. This part of Nicaragua is traversed by several ridges, some of whose summits attain a considerable altitude. Between the ridges extend many good-sized valleys, the principal being those formed by the larger rivers of the country. The northernmost part of this ridge, which is the most elevated, is the only remaining part of the state that belongs to the plain of Nicaragua, of which, however, the larger portion forms the Mosquito territory. This plain is but little elevated above the level of the sea. It is an arid tract of Nicaragua which occupies a large part of the Nicaraguan plain, and is about 120 miles above the Caribbean Sea. Along the rivers it is wooded; the rest of the plain forms extensive savannahs, covered with a rich verdure, and presenting occasionally a clump of high trees. The climate being excessively hot and moist, the white races have not formed any settlements on this plain, and it is only inhabited by independent aboriginal tribes.

The few rivers which in Nicaragua fall into the Pacific, are of small extent and little consequence. Those falling into the Atlantic are longer and more important. Two considerable streams rise, as already mentioned, in the northern part of the republic, the Segovia and the Escondido; the sources of several others are in the same region. These rivers and their outlets are far apart—that of the Escondido being near the southern, and that of the Segovia towards the northern end of the Mosquito coast. The Segovia flows past the town of the same name, but both rivers belong more to Mosquito than to Nicaragua territory. At the mouth of the Segovia is the town of Moyagalpa, which forms the boundary between Nicaragua and Costa Rica, and falls into the Caribbean Sea, near 11° N. lat. It is by means of this river and the Lake of Nicaragua, that one of the two great lines of communication is proposed to be opened between the Atlantic and Pacific oceans. The river San Juan is the only channel by which the Lake of Nicaragua discharges its waters into the Atlantic. The Lake or Lagoon of Nicaragua is an inland sea, of a brackish nature, about 100 miles long, broad where widest, without narrowing much at either end. It is the reservoir of a great extent of mountainous country, and is deep enough to be navigated by vessels of considerable size, having about 100 yards from the beach generally a depth of about 2 fathoms; and at a greater distance from 5 to 16 fathoms of water along the southern and western banks. It is only very shallow along the north-east shore for a mile or two upwards into the lake. It contains several islands, among which that of Omotepac, near the southern shore, is remarkable for its fertility and population, inhabiting it a numerous and industrious tribe of Indians, who have a small town, Moyagalpa, possessing cattle, and are independent. A quite different scene presents itself about the eastern extremity of the lake; its breadth varies from 100 to 400 yards. About the middle of its course the San Juan receives from the south the Rio San Carlos, and lower down the Serpiqui. About 20 miles from its mouth the river divides into two arms, of which the southern and wider is called Rio Colorado; the other (the San Juan) enters the sea near the harbour of San Juan del Norte. The depth of water in the upper part of the course of the San Juan at low water is about 3 fathoms, and the river is but shallow that rapids are produced, and it contains numerous islands. The lower portion of the river, below its bifurcation, is generally shallow. The mouth of the San Juan has a bar with seldom four feet of water upon it. The winding course of the river is somewhat under 100 miles. On the Pacific side there are, however, greater obstacles to the communication between the two oceans than that presented by the channel of the San Juan. At the narrowed part the distance between the hills that form the channel is about one mile, and the depth of water, except in a few places, is not more than 2 fathoms. On the coast there is here the good harbour of San Juan del Sur, but the hills upon it rise to between 400 and 600 feet, presenting a formidable barrier to the construction of a canal, while the difference of level between the lake and the sea is 130 feet. It is proposed to form a channel across this barrier, which might perhaps be in a measure avoided, but the canal would of course be longer. Whether such a canal ever will be formed it would be hard to predicate; especially since the completion of the railway across the isthmus of Panama has provided so much more rapid a route. But even in the absence of the canal this route has been largely adopted. In 1850 the governments of England and the United States concluded a treaty by which they agreed to co-operate in the establishment of a secure and direct line of communication between the two seas by way of the San Juan River and Lake Nicaragua, to be open on equal terms to all nations, with a free port at each end of the line. A company was formed for constructing a canal, improving the navigation of the San Juan, and establishing a navigation route through the Lake in the latter part of the 1850's. The Nicaragua Transit Company have been unable even to attempt to carry out the first and most arduous part of their task, but they have established steam-boats of light draught to navigate the river, and organised a line of carriages to convey the passengers over the lakes to and from the terminus on the Pacific. During 1854 a very large number of passengers to and from California adopted this route, and it was asserted in some of the advertisements of the line published in New York, that not only was "the Nicaragua Transit route the shortest, safest, and by far the most comfortable and healthful," but that passengers by it had "to travel but 19 miles of land carriage over a good macadamised road." Long before the establishment of this route communication between the two oceans had been attempted by various means. The first attempt was made by the pirates of Margarita, who used the piraguas of from 5 to 10 tons burden. The passage from Managua to the Gulf of Fonseca, is usually made by the piraguas in about 8 days, whilst the distance, measured against the stream, occupies from 12 to 16 days. It has been proposed by some as more advantageous to unite the Lake of Managua by a canal with the harbour of Realejo. The road in its width there is R it is deep, enough for vessels without being rocky. Besides this, the canal would terminate in the port of Realejo, one of the best harbours on the west coast of America, while that near Nicaragua would end in the smaller harbour of San Juan del Sur. But this canal would be more than twice as long as the other; in addition to which, the Tepitapa, which unites the Lake of Nicaragua with that of Managua, must be rendered navigable. The lake of Managua is 35 miles long, and fifteen miles broad, and forms a considerable size; but the Rio Tepitapa, which brings down the water from the Lake of Nicaragua, and is about 25 miles long, has falls which, in the dry season, are from 6 to 8 feet high, and also several shoals. These obstacles could only be avoided by a canal cut through the level ground on the northern side of the Rio Tepitapa.

The climate of the Plain of Nicaragua, as stated above, is hot and moist, and so unhealthy as to have caused it to be left to the aboriginal inhabitants and occupiers of the natives and Indians. The weather is generally settled, the occasional rainy seasons are very short. The thickly wooded banks of the San Juan River are an exception to this observation. The shores of the Pacific, where the population is denser, are also very hot and somewhat humid, but do not appear to be particularly unhealthy, except when the rainy season is in progress, when the town of the Bay of Panama is almost over-run with disease, and there ever there are comparatively few inhabitants. The hilly districts between the coast and the western banks of the lakes are much milder and more salubrious, as is also the mountainous country of the north. There are regular dry and rainy seasons, as in other parts of Central America, the only difference being that the rains last somewhat longer, and fall in larger quantities. In the hilly country west of the lakes occasional showers also occur out of the regular rainy season.

The soil throughout the occupied districts appears to be very fertile, but agriculture is in a rude state; the roads are almost everywhere insufficient, ill made, and ill kept, and even are almost the only animals of draught. Although therefore Nicaragua might with propriety be included in a general list of countries where people furnish vast quantities of agricultural produce for other countries as well as for the supply of a greatly increased population, it really affords little more than suffices for the wants of the whole country, and is not, beyond the Chili of considerable abundance, and form the staple food of the people. Some wheat is grown in the north, chiefly for use in the cities. Sugar, indigo, cotton, coffee, cocoa, and tobacco are all grown, but, except indigo, not to any great extent. There is a great wealth of fruit trees, and except oranges, lemons, &c., ripe well; and garden vegetables flourish, but little attention is paid to them except by the Indians, who cultivate them for sale in the cities. Indigo, Nicaragua, and Brazil wood, and some other timber and dye-
woods and hides are at present the chief articles exported. Cattle are among the principal sources of wealth, very large numbers of them being kept on the plains along the eastern sides of the lakes. Fish are plentiful in the lakes, in which also crocodiles are found. Along the coast pearls used to be obtained. The mineral resources of Nicaragua have not been very diligently explored. Gold and silver have been found and worked, but not extensively; copper has also been found.

The farmers are nearly confined to the coarser goods required for home consumption. The chief articles made are coarse cotton and woollen cloths; the cotton being dyed of a purple colour, obtained from a shell-fish caught in the vicinity of San Juan del Sur, is in great request among the inhabitants. The appearance of any European dyed goods on account of the greater durability of the colour.

Nicaragua is divided into five departments, which are named after their respective capitals—Segovia comprises the north-eastern part of the territory; Leon, the north and north-western; Managua, the district south of Leon; Granada, that south of Managua; and Nicaragua, the most southern part bordering on Costa Rica. Leon is the political capital. The following are the principal towns; the populations are merely local approximations.

Leon, the capital of Nicaragua, contained not many years ago, a population of 32,000 inhabitants, but the civil conversations within the town have reduced it to half that number, and it has become a mere collection of that group of villages situated on the road which leads from the best-cultivated districts of the state to the harbour of Realejo, in 10° 28' N. lat., 86° 02' W. long. The city occupies a considerable area, and contains a cathedral, several churches, a university, Trinity, and a New College. In a very short time after the capture of Granada, on the north-western bank of the Lake of Nicaragua, population about 15,000, carries on some trade with Jamaica by means of the river and harbour of San Juan, contains several churches and convents; but has no features requiring further notice.

Managua, on the south bank of Lake Managua, is a considerable place containing 10,000 inhabitants. Managua, some little distance S. of Managua, has a population nearly equal to it, but almost all Indians, who are engaged in commerce with the adjacent populous country, and in the manufacture of the various articles of domestic requirement in which they display much skill.

Nicaragua, about two miles from the west bank of Lake Nicaragua, contains, with the suburb of San George, some 15,000 inhabitants, and is surrounded by a district noted for its fertility, especially in cacao and grapes.

San Juan del Sur, on the Pacific, S.W. of the town of Nicaragua, is a populous village of some 2000 inhabitants; it was the old selection as the Pacific port for the Nicaragua line of communication between the two oceans. The harbor, as already mentioned, is small but convenient, and possesses good anchorage.

Managua, on the Rio de Segovia, is a small place, whose only claim to notice is that of being the capital of the department of Segovia, the least populous section of the republic. The country around is fertile and healthy, and its mineral wealth is believed to be considerable.

Nicaragua is nominally a Republic with a senate and a chamber of deputies, but the government is really vested in a dictator with the title of Supreme Director. After the declaration of independence, and the formation in 1842 of the republic of Granada, there were few inhabitants of Nicaragua. The British government of the Conch Republic (Granada, S. W.) Nicaragua formed one of the federal states until the dissolution of the union, when, like the other states, it became an independent republic; and, like them, all hopes of its progress have been since arrested by constant internal discord.

The Emperor Paul having been assassinated March 23, 1801, Nicolas was left entirely to the care of his mother, who appointed General Janosfeld his governor, and selected the Countess Lieven and the German philologist Adelung as his principal teachers in languages and literature, and Counselor Storch as his instructor in general politics and other sciences and arts suitable to his rank and station. He acquired the power of speaking the French and German languages with as much facility as the Russian, and early manifest

After the termination of the great European war in 1814, Nicolas was sent to travel, and visited some of the principal battle-fields. In 1816 he came to England, where he met with a cordial reception. He afterwards made a tour in the chief provinces of the Russian empire, and returned to St. Petersburg, 1817, accompanied by his niece Frederica-Louisa-Charlotte-Wellhimbarn, eldest daughter of Frederic William III., king of Prussia, and sister of Frederic William IV., the present king. She was born July 18, 1796, and her distinguishing name was Charlotte, but on her marriage and entering the religious state she assumed the names of Alexandra Fedorovna.

The Emperor Alexander I. having no issue, his next brother Constantine was the legitimate heir to the throne; but, by a document signed August 30, 1823, Constantine renounced his claim to the imperial dignity, and nominated himself the autocrat of Poland; so that, when Alexander died at Taganrog, December 1, 1826, Nicolas immediately succeeded him. He did not however become emperor without a struggle attended with much difficulty. The government had organized a considerable force before the death of Alexander among the officers of the Russian army and those of the nobility who were friendly to a constitutional government; and the soldiers and people were taught to believe that the new emperor was a mere tool of the reactionary party, and desirous of being restored to their former condition by forcible means. When the troops were assembled in the great square fronting the Imperial Winter Palace of St. Petersburg, in order to make a manifestation of their allegiance to the new emperor, the officers, just as the ceremony was about to commence, stepped forward out of the ranks, denounced Nicolas as a usurper, and proclaimed Constantine as their rightful saviour. The soldiers followed their officers, with cries of "Constantine and the Constitution!" Milliards, who was then minister of state, and president of the council, the main body of the army, and the archbishop, in his ecclesiastical robes, endeavored to suppress the hostile demonstration, but in vain, and the people showed signs of sympathizing with the troops. At this critical moment Nicolas came forward, and, boldly confronting the officers and soldiers, called out with a loud voice, "Return to your ranks—obey—kneel!"—The czar's majestic form and undaunted bearing, his pale but calm and stern composure, and the reverence with which the Russians received him, gave to the scene an air of dignity and grandeur, and the soldiers to kneel ground their arms. The first outbreak was thus checked, but the conspiracy was not suppressed till artillery and musketry had torn asunder their missiles of destruction among the gathering masses of the infuriate and excited people, and forty officers and five hundred soldiers were executed. Others were sent to the mines of Siberia, where Nicolas continued their punishments with unappeasable severity. He was crowned at Moscow with great pomp and ceremony, September 3, 1828; and at Warsaw, May 24, 1829.

Soon after his coronation, in 1826, the Emperor Nicolas commenced a war with the Shah of Persia, which lasted till the victory over the Persians by Field-Marshal Paskevich, October 14, 1828. Along the coast from the banks of the Darda and the Danube to the mouth of the Volga, as well as to the fortress of Braila and Varna. In the campaign of 1829, General Diehich took the fortress of Silistra, defeated the main army of the Turks at Shumla, crossed the Balkan, and occupied Adrianople, which he left to one of his colleagues. The campaign was exchanged for September 14, 1829. By this treaty, Nicolas obtained for Russia, besides a large sum as indemnification for the expenses of the war, liberty to trade in all parts of the Turkish empire, trading navigation on the Danube, free passage of the Dardanelles and Bosphorus, and other additions of territory as well as of political power.

On the 29th of November 1830 an insurrection broke out in Poland. The Polish troops having joined the insurrec-
The Emperor Nicolas was upwards of six feet in height, muscular and well-proportioned, with handsome features. In his personal habits he was simple, abstemious, and indefatigably industrious. He had a taste for the fine arts, and collected a magnificent library, but his favourite pursuits were connected with the military sciences and military operations. In his political principles he was professedly despot. He has been heard to say, "I despise the despotic Russian government; that suits the genius of my land." The object of his public life were the increase of the power of Russia and the extension of her territories to the east, west, and south, by unscrupulous diplomacy, and, when that failed, by war. His grand purpose is now known to have been the possession of Constantinople. By means of that unrivalled military and political position, he trusted to have superseded the Sultan in his empire, and to have become the dominant power in Eastern Asia.

NICOLAS, Sir Nicholas Harris, was born on March 10, 1799, the fourth son of John Harris of Cornwall. He entered the navy early, and attained the rank of Rear-Admiral on September 18, 1816, after having distinguished himself in the operations of the Porte against Calabria. As he ceased to be employed after the close of the war he turned his attention to antiquarian literature, and his first production was 'The Life of William Davison; Secretary of State and Privy Councillor to Queen Elizabeth, 1550-1570, published by himself from the 1st to the 9th of June. In 1849 he sent a Russian army into Hungary in aid of the Austrians, and the subjugation of that country was accomplished in the month of August of that year.

The last and most important event in the reign of the Emperor Nicolas was the recent war with Turkey and the Western Powers. It was the only unsuccessful and disastrous war in which he had engaged, and the reverse his army experienced probably occasioned a degree of excitement in the French public as well as Russia. It commenced by the emperor's minister Benckoff in March 1853 demanding a right of protectorate over those subjects of the sultan who belong to the Greek Church. The claim was refused, and a Russian army occupied Moldavia and Wallachia. The Turkish fleet, which was destroyed at the same time the Porte declared war against Russia, and applied to France and England for their promised aid. A Turkish army under Omar Pasha occupied Shumla and the fortresses on the Danube; in November he threw a body of troops across the river opposite Wilin, and fortified a position at Olteniitz, on the left bank, which was retained till the termination of the war. The destruction of the Turkish fleet at Sinope in the same month was followed by the advance of the Allied forces across the Bosphorus. The English and French armies were next landed and encamped near Constantiopolis, whence they removed to the vicinity of Varna. In March 1854 the Russian army crossed the Danube, and besieged the fortress of Silistra, but after great efforts and an enormous loss of men was compelled to raise the siege on the 15th of June, and to retreat across the Danube. The Anglo-French army landed in the Crimea, September 14, 1854; won the battle of the Alma; by a flank movement captured Balaklava, November 29, 1854; and commenced the siege, which, after a severe struggle, the facts of which are well known, was terminated on the 9th and 9th of September 1855, by the capture of the town and all the forts on the southern side of the harbour of Sebastopol.

Meantime, before this great feat had been accomplished, the Emperor Nicolas died at St. Petersburg on the 2nd of March, 1855, and was succeeded by the present emperor Alexander II. The Empress Alexandra survives him, and so has left issue four sons and two daughters: Alexander, born April 29, 1818; Maria, born August 18, 1819; Olga, born September 11, 1822; Countess, born September 21, 1827; Nicolas, born August 5, 1831; and Michael, born October 26, 1834.
lived to complete two volumes. Among his numerous other works were several on the statutes of various orders of knighthood, for which in 1831 he was made a knight of the Hanoverian Guelph Order, and in 1832 chancellor of the Ionian Order of St. Michael and St. George. After a life of industrious industry, he spent nearly every one of which has great historical or professional merit, he died at Cape Coré, near Boulogne, on August 3, 1848.

NICOPOL, NIKOPOL, in Turkish Tekhagani-Kul, the ancient Nibopolis ad Istrum, a city in Bulgaria, in Europe. Nibopolis is either a name or a place, but the Romans, basing their actions on the right hand of the Danube, 80 miles S.W. from Bukharest, 250 miles N.W. from Constantinople, and has about 10,000 inhabitants. The Osma on the Bulgarian side, and the Alata on the Walachian join, the Danube just above the town, but the ancient city, which was surrounded by a trench and palisades. The Christian quarter, which is the largest part of the town, lies beyond the hazzar, and is open to the plain. Nissa is now the chief town of the palaele of Sophia; it is called Nisch by the Turks. It is the residence of the bishop of the Chalcedon archbishop. It is situated at the key to military communications between Thrace, Bulgaria, and Servia, the fortifications of the town are mounted with a considerable number of guns of large calibre, and in good order. The place of Nisa belongs with his city, within the church and the little Balkan, two ramifications of the Hammus, is one of the most beautiful, fertile, and well-tilled districts in Bulgaria. The town was taken by the Turks under the Sultan Amurath I. in 1388, on the march to the battle of Kosovo. A couple of miles above Nissa on the road to Sophia, the site of an action between the Turks and Serbs in the same year is marked by a tower of skulls, which is more terrible in name than in reality. It was constructed of stone and lime, but externally heads were imbedded in the mortar. The Turks were said to have known it to be having in the course of time removed almost all of them for the purpose of interment, but their places are marked by rows of round holes. The tower is 10 feet square, 16 feet high, covered with broken tiles and windows, and is filled with wind in it. The interior is said to be a favourite retreat of snakes and lizards. The Anastatians took Nissa in 1737.

NOTICULUS, a genus of Animals usually referred to the class Aschelus, Asceliina. One species only of this genus has been found in S.W. Europe, and occurs in prodigious numbers along the coasts of England, and is the most frequent case in this part of the world of the phosphorescence of the ocean. It was first discovered by M. Siviray in 1810.

According to M. Siviray the Noticulus is a spherical gelatinous mass, provided with a long filiform tentacle or appendage, presenting a mouth, an osphagus, one or many stomachs and ramified ovaries, and thus possessing a certain complexity of organisation. De Blainville confirmed Siviray's account, and placed Noticulus, without doubt. The most erroneously, among the Diphyidae. On the other hand, Van Beneden Verhaeghe and Doyère, denying the relation of Noticulus with the Aschelus, and regarding its organisation to be of a much more elementary character, relegated it to the Rhizopoda.

To this doctrine M. de Quatrefages also attaches the weight of his authority in his valuable essay 'Observations sur les Rhizopodes' which appeared in the Revue de la Nature for 1850. M. de Quatrefages does not admit the existence of any true mouth or intestinal canal, and considers that the so-called stomachs are nothing but ' vacuoles' similar to those observed in the Rhizopoda and Infusoria.

Krohn.) Which stalk of the pebble might be, a filiform tentacle, equal in length to about the diameter of the body, depends from it, and exhibits slow and motions when the creature is in full activity. I have even seen a Noticulus appear to push repeatedly the tail in the direction of its tentacle.

The body is composed of a structureless and somewhat dense external membrane, which is continued on to the tentacle. Beneath this is a layer of granules, or rather a continuous sheet of granules, which are scattered without any very definite arrangement. From hence arises a network of very delicate fibrils, whose meshes are not more than 1-3000th of an inch in diameter, and these gradually pass internally—the reticulation becoming denser and denser. Thence the granules, in a convergent direction towards the stomach and nucleus. All these fibrils and fibrils are covered with minute granules, which are usually larger towards the centre.
After describing minutely the structure of this creature, Mr. Huxley concludes—

"...on the day I have observed lead me to believe that *Noctiluca* has a definite alimentary cavity, but I am inclined to think that this cavity has an excretory aperture distinct from the mouth. The funnel-shaped depression in the post-oral area in fact always appeared, when I could obtain a view, in the same position as a special process of the stomach. On one occasion I observed the sides of this process to be surrounded by fusiform transversely striated fibres or folds; I could not determine which."

Krohn states that he repeatedly saw the egglayer "in* in the collection of the body*" but he could not determine at what exact point, and he inclines to think it must have taken place through the mouth.

I am equally unable to bring forward direct evidence on this point, but in the existence of a distinct anus is founded simply on the structural details of the body.

"In front of and above the gastric cavity is the nucleus, described by Verhaeghe and Krohn. This is a strongly refracting oval body of about 1-400th of an inch in length, which, by the action of acetic acid, assumes the appearance of a hollow vesicle. The anterior radiating fibres pass from it; the posterior from the alimentary canal."

"Quatrefoils and Krohn consider that a process of fusiform multiplication takes place in *Noctiluca*; both of these processes are observed and noticed with rapture. According to the latter writer, division of the body is preceded by that of the nucleus. I have not had the good fortune to meet with any of these forms, and the only indication of the former is suggested by long blackish bodies which consisted of a number of granular vesicular bodies, of about 1-900th of an inch in diameter, scattered over the surface of the anterior and inferior part of the body."

Such as what repeated examinations lead me to believe is the structure of the body; but if the preceding account be correct, it is obvious that the animal is no Khizoped, but only from the lower ranks of the Protocorallia to the highest.

The absence of a dental armature, and of a distinct anal aperture, are structural peculiarities which greatly increase the affinity to such forms as *Colpoda* and *Para-

"*Noctiluca* might be regarded as a gigantic Infusorium with the grooved body of *Colpoda*, the long process of *Trachelus*, and the dental armature of *Nassula* united in one animal."

"On the other hand, the general absence of cilia over the body, and the wide differences in detail, would require the constitution of at least a distinct family for this singular creature."

In the same volume of the *Microscopical Journal* is an account of this creature by Dr. Woodham Webb, of Lowestoft.

**NOCTUA**, a genus of Insects belonging to the Nocturnal Lepidoptera, is described and figured by Kolen. It is a very pretty species.

**NOLANACEAE.** A natural order of Plants, having elongated or prostrate stems; alternate leaves without stipules. Flowers usually showy; calyx 5-parted, valvate in asivation; corolla monocarpous, with a pistil asivation usually thickened in the tube; stamens 5, equal, inserted into the tube, alternate with the segments of the corolla; anthers oblong, 2-celled, bursting longitudinally; pistil composed of several carpels, either distinct with a single style, or partially combined into several sets, with a single style seated on a smooth disc; stigma somewhat capitate. Fruit inclosed in the permanent calyx, constructed like the pistil; pericarp woody, often a little succulent; seeds ascending, solitary; embryo curved with either straight or double cotyledons in the midst of a small quantity of albumen; radicle next the hilum. This little order is remarkable for the various modes in which its carpels are disposed without ever being consolidated. In one genus there are 8, and they are distinct; in another there are 50 combined in fours, in a third the combination is irregular, but the view, to be obtained in many, is that none of these are all wholly distinct. The species are all South American, and chiefly from Chili. Their uses are unknown. There are 7 genera and 30 species.

The act establishing the County Courts, 9 & 10 Vict. c. 95, has established one exception to the general rule that a plaintiff cannot be nonsuited against his will, by expressly authorising the judge to enter a judgment of non sui, an enactment for which some of the commentators on the Act have attempted to assign any reason.

The practice of giving judgment in the Supreme Courts, as in case of a nonsuit, has ceased since the passing of the Common Law Procedure Act, 1852, which provided a simple and more rational method of putting an end to the action. (See 24 & 25 Vict. c. 344.)

It may be added here that the Crown, being theoretically present in all our courts of justice, cannot be nonsuited; but the Attorney-General, or his representative, may always enter a nonsuit if the defendant himself, in his own person, moves for that purpose.

**NORTH AUSTRALIA.** At present the designation applied to all that part of Australia, comprising considerably more than one-half of the island, which lies north of the parallel of 29° S. lat. This parallel forms the northern boundary of what is commonly known as the South Australian Colonies, all of that of Western Australia remaining unsettled. Coburg Peninsula projects west-north-west from the mainland, between Mount Norris Bay on the north-east and Van Diemen's Gulf on the south-east. This is the section of the coast in that direction nearly 60 miles. The greatest breadth of the peninsula is in the narrowest part, where it is joined to the mainland by a neck of land of 5 miles in length, is 24 miles. On the north side of Coburg Peninsula is the deep inlet named Port Essington, which lies between 11° 6' and 13° 6' and 13° 18' E. long. The inlet, at its entrance, between Point Smith on the east and Vashon Head on the west, is 7 miles wide, and extends south by east about 18 miles; its average breadth is 6 miles. The depth of water varies between 5 and 12 fathoms, and in some places reaches 22 fathoms within the port. There are 5 principal harbours, each of which extends inwards 3 miles, with a width of about two miles; the depth of water is 5 fathoms, with a bottom of stiff mud and sand. These harbours are defended by detached reef and solid breakwaters, and secure anchorage. The port forms one of the finest natural harbours in the world; it may be entered with safety both by night and day. Being within the range of the regular monsoon, it is accessible to the Malay and Bugis trading proas, and to the ships of the Anglo-Indian Revenue and the Red Ensign.

The solt of the peninsula is in general indifferant, but in many places it is good, principally on the low flats and hollows, and near tracts which are swampy in wet weather. There are few vegetables, so that the country is almost barren during the dry season. The north-west monsoon, which begins in October, begins about November. The rain during this monsoon falls in torrents, but seldom continues above two or three hours at a time. The general range of the thermometer at this season is from 69° to 90° F. in the shade. The termination of the monsoon is indicated by squalls, and usually a tempest in the early part of April. In May the thermometer ranges between 75° and 80°, the midday heat being 88°. The average heat of the whole year is 85°, or about that of the coast of China.

With the expectation that, if there were an establishment on the north coast of Australia, it would be resorted to by the traders of the eastern portion of the Indian Archipelago, and the coast of the south-west of India and the South American, and Indian commodities, a settlement was made in 1834 for a settlement at Aspley Strait, and called Fort Dundas, and another in 1837 on the Coburg Peninsula, and called Fort Wellington, but both settlements were abandoned in 1828. In 1838 another attempt was made, and the town of Victoria was founded on the western shores of Port Essington. In 1846 the population was stated to be about 60. The Malays did not settle there, as was expected: the climate is unsuitable to Europeans, and the settlement has been abandoned.

The coasts, islands, and lakes of North Australia have been surveyed and named, but of the interior hardly anything is yet known. Melville Island, on the northerm coast, between 11° and 18° S. lat., 130° 20' and 131° 34' E. long., is one of the largest of the islands. The area is 2,303 square miles. It is separated from Bathurst Island, which lies west of it, by Aspley Strait, which is from 2 to 4 miles wide and 46 miles long. From Coburg Peninsula it is separated by Dundas Strait, which is 15 miles wide. The natives lead a wandering life, and are occupied in fishing, gathering and other marrobial animals, and during the wet season on fish, turtles, crabs, and other shell-fish. Their vegetables are the cabbage-palm and the sago-palm. (See South-East Australia.)

**NORTH-WEST PASSAGE.** In the article North-West Passage an account is given of the series of voyages undertaken for the discovery of a passage westwards from the Atlantic Ocean to the Pacific, through the seas which surround the North Pole, and the narrative is there brought down to the year 1858. We now add an account of

3 N 2
in the subsequent voyages of exploration, and also of the expeditions sent out in search of Sir John Franklin and his associates.

In the year 1846 the British government sent out another expedition to the Arctic Seas for the purpose of discovery and settlement, under the command of Sir John Franklin. They sailed from the Thames on the 23rd of May, and on the 26th of July were spoken by the Prince of Wales whaler at the entrance of Lancaster Sound. In consequence of the ship not having been made ready in time, a series of searching expeditions were successively fitted out and sent to the Arctic Seas, all of which failed in the main object of finding the missing ships or their unfortunate crews, but one of which discovered the long-sought secret of a North-West Passage.

In 1848 the Enterprise and Investigator, under the command of Sir James Ross, were sent out, and reached Lancaster Sound on the 28th of August. They were not able to get farther west than Leopold Harbour, near the entrance of Prince Regent's Inlet, 73° 6' N., 90° 15' W., long, where they wintered. After the ships were liberated from the ice, they were swept eastward by a mass of drift ice into Lancaster Sound, and Sir James Ross brought the ships back to England early in November 1849. In 1848 Sir John Richardson and Mr. Rae made a voyage in boats from the mouth of the Mackenzie River eastward, but without success.

Another searching expedition was fitted out by the British government in 1849. Captain M'Clure was appointed to the command of the Enterprise, and Captain M'C lure to that of the Investigator. The two ships left the Thames January 10, 1849, and sailed in company round Cape Horn. Captain M'C lure reached Point Barrow, at the north of the Strait, on the 1st of February, 1849, and then bore to the east, just keeping clear of the American coast. Captain Collinson having failed to force his way through the pack-ice of Behring's Strait, sailed for Hong Kong, where he wintered. Captain M'C lure reached Charles Bar on the 4th of September. From this point high land was observed to the east-north-east, and named Baring Island. Two days afterwards, still farther to the east-north-east, more land was observed, and named Prince Albert Land. This land of Baring's Strait, with Barking Land and Victoria Land, and extends northward to 73° 31' N. lat. The Investigator was then navigated northward through a channel which separates Baring Island from Prince Albert Land, and which Captain M'C lure named Prince of Wales' Strait. In sailing up this strait the Investigator several times narrowly escaped destruction, but on the 8th of October was firmly frozen in near the northern extremity of the strait, and remained there during the winter. Parties were sent forth by the ship, and entertained the Investigator, who named Prince of Wales' Strait opens into Barrow Strait, and thus was made the first discovery of a North-West Passage.

On the 14th of July 1851 the Investigator was freed from the ice, and the great exertions were made to pass out of Prince of Wales' Strait. The ship made her way through the 13th of August, being then in 73° 14' N. lat., 115° 32' W. long, strong winds from the N.E. drove the masses of ice against the ship, and Captain M'C lure, thus baffled, resolved to sail southward back again down Prince of Wales' Strait. Having accomplished this, he sailed along the southern coast of Baring Island, and then northward along the western coast. At length, after incurring many risks and encountering difficulties which could only have been overcome by a rare combination of indomitable courage, admirable seamanship, and scientific resource, the Investigator, having rounded the whole island except a portion of the north shore, was got to the station which Captain M'C lure named Mercy Bay, September 24, 1851. This station is on the northern side of Baring Island, in 74° 6' N. lat., 117° 34' W. long., on the south side of Barrow Strait. Here then was the discovery of a second North-West Passage; and had there been open water in the east the whole voyage into Baffin's Bay might have been avoided, but the Investigator was frozen up in Mercy Bay on the very day it was entered. The north side of Baring Island was ascertained to be the Banks' Land which Captain Parry saw from Melville Island in 1818.

Melville Island is distant about 60 miles N. from Mercy Bay, and in April 1858 Captain M'C lure sent a travelling party across the ice to it, who deposited a document there, giving an account of the proceedings of the expedition, and of the position of the Investigator. In April 1853, only a few days before Captain M'C lure had made arrangements for deserting his frozen-up ship, the document was discovered by Captain Kellett's officers, and Lint. Pim, with a party of sailors carrying provisions, was sent from Melville Island to search for the Investigator. They were met with Captain Kellett from the time of her rounding Barrow Point in August 1850, where Captain Kellett was then stationed with the Herald, and who made Captain M'C lure a signal of recall, till April 1856, when Captain Kellett sent a party under Lieut. M'C lure and Captain of the Herald, the arrangement of the meeting may be easily imagined. Captain M'C lure remained with his ship till the spring of 1854, when he and his crew were brought to England by the ships belonging to Sir Edward Belcher's expedition. The Investigator, as far as is known, still remains frozen-up in Mercy Bay.

Captain Collinson, after wintering at Hong Kong, passed through Behring's Strait in 1851, and followed very nearly the track of Captain M'C lure up Prince of Wales' Strait, whence he also was obliged to return. He wintered in 1851-2 in 71° 36' N., 117° 36' W. long. The winter of 1852-3 was passed in Cambridge Bay, Wollaston Land, 69° N. lat., 105° 30' W. long. Still struggling on, the winter of 1853-4 found the Enterprise in 8° N., 145° 30' W. long. On the 15th of July, 1854, the Enterprise was released from the ice, when Captain Collinson commenced his return voyage. He reached Point Barrow on the 9th of August, and Point Clarence on the 21st.

The Arctic expeditions may be more briefly noticed. In 1850 Captain helmet with the Herald and Plover reached 72° 51' N. lat., 163° 48' W. long. In the same year the Advance and Rescue, two small brigs, were fitted out at the expense of Mr. Grinnell, an American merchant, and commanded by his son, a captain of the fleet at the entrance of Washington Harbour. In August, 1850, Captain Oommanny and Captain Penny conducted travelling parties by order of Captain Aultin, who commanded an expedition sent out by the British government. They many discovered that Sir John Franklin's expedition had passed the winter of 1845-6 at the mouth of the Wellington Channel, in a bay between Cape Ryle and Beechy Island. Captain Penny also explored the Wellington Channel to a distance of 80 miles from the mouth, and discovered a strait bearing to the north-west, which he named Victoria Channel. Dr. Rae and Commander Pullen also conducted expeditions in 1850.

In May, 1851, the Prince Albert, a small vessel, was equipped at the expense of Lord Franklin and placed under the command of Capt. William M. Pen, 70° 50' W. Albert passed through Lancaster Sound, and wintered in Bathy Bay in Regent's Inlet, on the east side of North Somerset. In March, 1852, Mr. Kennedy, with M. Bellot, an enterprising French navigator, made his way through the sheet ice of the northward along the east side of North Somerset till they reached Brentford Bay, which they ascertained to be a channel connecting Regent's Inlet with Victoria Strait, the northern part of which, called Peel Sound, enters Barrow Strait. They stated that they had fully proved that North Somerset is a large island, separated from Boothia Felix by the Brentford channel, which they named Bellot Strait, and found to be 15 miles long and 2 miles wide. They next travelled over the ice of Victoria Strait, and over Prince of Wales' Land due west as far 100° W. long., then northward to the south-east angle of Oommanny Bay, then eastward to Brown's Bay in Peel Sound, whence, following the coast-line northward they arrived at Cape St. John. All the officers of the Enterprise had left the ship on May 30th, after an absence of 96 days, and having travelled on foot and with sledges 1100 miles.

Captain Ingfield, in the small screw-steamer Isabel, sailed from the Thames July 6, 1855. He proceeded along the east side of Baffin's Bay, and eventually found that it contained two large openings to the north-eastward. He entered Smith's Sound at the head of Baffin's Bay, and on the 27th of August attained 78° 36' N. lat., where he wintered. The next year he gave the islands covered with ice. He was driven back by a violent gale, and afterwards entered Jones's Sound, which he penetrated to 84° W. long., the north coast there suddenly tending to the north-west, whilst the south shore continued its direction westward, and he could not by any means have reached the Isabel returned to England in November, 1852.

A searching expedition under Sir Edward Belcher was sent out in 1852. He proceeded up the Wellington Channel, and
wintered in 76° 52' N. lat., 97° W. long. While here explorations with boats and sledges led to the discovery of various countries never before visited. The northern side of this bay was named North Devon; the western side is Cornwallis Land, which is separated by a strait from Bathurst Land still farther west. A group of islands in 78° 10' N. lat., was named named Missions Land, and Sir E. Belcher found the sea open in the latitude of James's Strait. His words are, “Polar Sea as far as the eye can reach.”

The gallant young Frenchman, Lieutenant Bellot, in attempting to convey the government despatches from Caledon to Sir E. Belcher, was blown from the top of a hummock of ice, and was drowned. Sir E. Belcher's ships were liberated from the ice July 14, 1853, and he returned to England the same year. In 1853-54, Dr. Kane, in the Arctia, passed through Smith's Sound, and reached 78° 43' N. lat.

In October, 1854, Dr. Rae returned suddenly to England from the vicinity of Boothia Felix, for the purpose of announcing to the British government that he had obtained some relics which had belonged to Sir John Franklin's companions. He stated that he had met with some Esquimaux in Pelly Bay, who were in possession of watches, silver spoons, telescopes, and other things, which had belonged to the officers and seamen of the Erebus and Terror. These he procured for the Government and to the scientific societies. He had also been informed that the Esquimaux had informed him, that in the spring of 1850 about forty of the ships' crews were seen (but not by Dr. Rae's informants) near the north shore of King William's Land; that they were dragging a boat over the ice, locked with ice, but it was较好的 indication that the party was returning from the north of the country.

The two expeditions which it was stated the Admiralty intended to send out in November 1854 were not sent. Lady Franklin, however, chiefly at her own expense, has sent out an expedition in the Fox, under the command of Captain M'Clinstock, which sailed from Aberdeen on the 1st of July, 1857.

The result of all these searching expeditions—of which we have only noticed the most important—has been the discovery of a passage from the Arctic Ocean to the Pacific Ocean, which may be entered from the Atlantic, or the Arctic Ocean, from the Pacific, namely, by the west coast of Baring Island, by the east coast of the same island, through Prince of Wales Strait, by Regent's Inlet through Bellot Strait into Victoria Strait, and probably also by Peel Strait into Victoria Strait. These passages, being all more or less encumbered with ice, may be of little or no commercial importance; but the long-sought North-West Passage has been discovered, many expeditions have been sent on, and the climate and soil of these islands and countries have been found and partly examined. Besides the geographical discoveries which have been incidentally noticed in the course of this narrative, it has been ascertained, by the explorations of Dease and Simpson, in 1821-23; of Henry, in 1849; by Dr. Kane, in 1853; and by Dr. Rae, in 1854-55, that the Victoria Land are continuous, forming the south coast of the largest of all the islands of the Arctic Sea, the western boundary being Prince of Wales' Strait, the eastern boundary Victoria Strait with its continuation Peel Strait, and the northern boundary Barrow Strait. The northern coast of this large island is deeply indented near the eastern end by Ommanney Bay and Osborne Bay, so named from the explorers. North Somerset is also, as has been stated, a large island, separated from Boothia Felix by Bellot Strait, previously called Brentford Bay; whilst Boothia Felix has been ascertained to be united to the American continent by an isthmus.

In many parts of these cold regions there is an extraordinary abundance of animal life, consisting of moose-deer, hares, ptarmigan, and other game. In 1851, Captain M'Cline says, “On the 1st of April we had 1000 lbs. of venison hanging at the yard-arms;” and in 1853, he says, “A supply of game has been sent up from Boothia Felix by Bellot in the winter, which has enabled us to issue a man twice weekly.” It seems also to have been ascertained, that north of Smith's Sound and the Wellington Channel there is an extensive Polar Sea, comparatively unencumbered with ice, which was seen by Dr. Kane.

NORTHERN SOVEREIGNTY. This name has been given, but perhaps not definitely, to an extensive tract of country which was annexed in 1848 to the British possessions in the north-west of the Drenthenberg Mountains, between the two great branches of the Orange River, the Ky Gareep and the Na-Gareep, comprising a triangular area of about 50,000 square miles.

The Drenthenberg Mountains, called also the Quattlibha Mountains, run parallel with the eastern coast of South Africa, at a distance varying from 60 to 90 miles from the shore. They rise to a height of from 6000 to 6000 feet, and tower over peaks and rocky ridges, interrupted only by ravines and gorges. The coast is for the greater part barren, and consists of a series of wide plateaus, which, sloping gradually downwards towards the lower coast of the Vaal River, terminate in plains of vast extent, sometimes containing numerous isolated and rocky hills, but generally quite flat and without trees. These vast plains are for the most part without a single human inhabitant, but afford abundant means of subsistence to countless herds of antelopes, quagga, and other wild animals. All the rivers fall ultimately either into the Kafir or into the Vaal River, and thus flow from north to south, and from west to east. The Vaal River, rising between 26° and 27° S. lat., and 39° E. long., about 300 miles W. of Delagoa Bay, in an interior range of mountains bounding the great plains of the north, flows east, south, and south-west till it meets the N. Gareep.

The principal affluent of the north is the Caledon; from the south it receives the Stormberg River, the Oorlogs, the Zeekee River, and others of less importance.

This portion of the continent, being remote from the sea-coast, receives its rain in thunder-storms, chiefly during the winter months, of which December and January are the wettest; the climate is cold, the climate and soil are then characterized by great dryness, though copious dews fall at night. The smaller rivers are dried up, and the ponds and lagoons are converted into swamps.

The White-Faced Antelope (Antilope albirostris), the Spring-Bok (A. euryceros), the Gnu (A. gnu), and the Quagga (Equus Quagga) seem to be in the greatest abundance. They are often seen in countless herds covering an immense extent of land, and grazing in the same place for months together. They are less numerous, and with buffaloes. Hyenas are abundant. Lions are very common. The hippopotamus is very common in the larger rivers. Ostriches appear on the great plains in considerable numbers. Timber grows on the slopes of the mountains, and the rivers are shaded with willows, lagoons and salt-marches, and some of the plains are covered with an incrustation of salt.

The white population is estimated to be about 6000, who are chiefly the residue of the Dutch farmers who, in the years following, emigrated from the Cape Colony, and are settled in villages and in small groups near the rivers. The native population is supposed to amount to about 100,000, who mostly inhabit the Malati Mountains. The Bushmen live among the isolated hills of the interior. The Grahmas, who are a mixed breed, arising from the intercourse of Europeans with the natives, are in considerable numbers. They are mostly settled along the banks of the N. Gareep, on the shores of Lake N. Gareep.

The colony has been distributed into four districts—Bloom Finetain, Caledon River, Winburg, and Vaal River. The principal town is Bloom Finetain; situated in 39° 8' S. lat., 36° E. long., on the high road from the Cape Colony to Natal. It is about 340 miles N. from Graham's Town. It contains about 1000 inhabitants; has an Episcopal church, a Wesleyan Methodist chapel, and barracks. Smithfield, Winburg, and one or two other villages, are inconvenient places. There are three or four mission-stations belonging to the British, French, and German churches.

The country appears to be well adapted for sheep pasturing and the production of wool. The climate seems to have a favourable influence on the fineness of the fleece. Small quantities of gold have been found in the neighborhood of Smithfield.

When the Dutch inhabitants of the Cape Colony emigrated
NYC

from it in 1836 and following years, they settled themselves at first in various parts of the territory which is now named the Northern Sovereignty. In 1838 a party of them went to Naafs, where they were treacherously murdered by the warriors of the chief Dinpann. [Nata, S. 9.] When the Dutch, who had conquered the natives and declared a republic, were obliged in their turn to submit to the English in 1842, the greater part of them fled into the Northern Sovereignty, where they founded the village called Winburg, and proclaimed a new Dutch republic. Little notice was taken of their proceedings till they began to expel from their farms the Dutch farmers who continued to acknowledge the British supremacy, and in 1845, under their leader Pretorius, prepared a large expedition to attack Adam Kok, a Griqua chief in alliance with the British. The chief applied to the colonial government, and two regiments were immediately sent to his assistance, who repulsed the revolutionary Dutch boers. On the 1st of February 1845, Sir Harry Smith, with the assent of the well-affected boers, erected the whole of the territory inclosed by the Ky Garsep and the Nu Garsep into a British colony. This led to another contest, in which Sir Harry Smith defeated Pretorius and his adherents on the 30th of August, 1845. Pretorius fled beyond the Vaal River, and the majority of the boers laid down their arms and submitted to the British government.

NORWOOD. [Surrey.]

NOSE, one of the external apertures of the respiratory system and the organ for the sense of smell. The portion of the nose by which odours are perceived, lies deep back in the cavity to which the external apertures of the nostrils lead; the portion which is prominent upon the face serves merely as the apparatus for inhaling the air which is impregnated with the odour. The most essential parts of the organ are the olfactory nerves, which come off from the olfactory root of the brain [Brain], and passing through numerous holes in the ethmoid bone, which is situated between the orbits and above and behind the nostrils, ramify on the extended surfaces of that bone and the turbinate bones which form on each side the chambers of the nose. The sensitive terminations of the nerves are placed on the surface of a delicate and very vascular membrane which lines the whole cavity of the nose, and which is constantly kept moist by the secretion of a small quantity of mucus, in which the odorous particles are caught and for a time retained.

The sense of smell varies considerably, both in degree and in kind, in different animals. It is evidently possessed by insects and many others of the lower animals, but the organs by which they exercise it are unknown. In the higher animals its degree of acuteness is in general marked by the extent of surface of the ethmoid and turbinate bones, over which the olfactory nerves are distributed. In man this surface is proportionally smaller than in other animals, in most of which, besides occupying the greater part of the interior of the face, it is increased by peculiar branchings and convolutions of the thin layers of the bones. Each species has also a sense of smell in some degree peculiar to itself; thus herbivorous animals, though possessing the most delicate power of discerning the differences of vegetable odours, have no evident faculty of discriminating those of most animal substances; while the carnivores, on the other hand, can scarcely distinguish any others than the last. Each species has a fine sensibility for those substances which are of the greatest importance to its own existence, and thus obtains at once a knowledge of their presence in places concealed from all the other senses. Man possesses the sense of smell for a very large number of substances, but not in a very acute degree for any of them. The difference appears the greater between him and other animals in consequence of the neglect of the exercise of this sense which is common (except for particular purposes) in civilized society; but the American Indians and some of the northern Asiatic tribes, by their constant practice in hunting, are said to have acquired a power of scent scarcely inferior to that of the dog.

The olfactory nerve is appropriated exclusively to the sense of smell, and is incapable of perceiving pain or any other sensation. Of the peculiarities by which in different animals it is capable of perceiving only certain odours, we know no more than of the nature of those odours themselves, of whose existence we have no other evidence than that of the sense which they affect.

The sense of smell serves as an adjunct to that of taste, and is subservient in most instances to the same purpose, of providing proper and avoiding injurious food for the sustenance of the body. By it many animals seek out their food, and all select from that which they obtain; and much of that composed sensation which we regard as taste is really due to the smell, as for instance the sensation of the flavour of aromatic substances, which is completely lost by closing the nostrils while we are eating them.

For the full perception of odours it is necessary that the particles charged with them should be drawn with some force into the nose, and we may stand for some time in a very strongly smelling atmosphere without perceiving it if we breathe only through the mouth. The most acute sensation is obtained by the sudden inhalation of a large quantity, or by a succession of short and quick inspirations.

NOTONECTA, a genus of Insecta belonging to the family Hydrocoris, of the order Hemiptera. N. planca, the Water-Boatman, is one of our commonest insects. It is about half an inch long, and swims upon its back in order the better to seize its prey.

NUNEATON. [Warwicks.] Usus. [Nys.] NUTRIENT, NUTRITION. [Food, S. 2; Tabaks, Orios, S. 1.]

NYCTAGINACEÆ, a small natural order of Hypoquysous Exogenous Plants, belonging to Lindley's Cenopodal Alliance. They have a tubular often coloured calyx, which separates from its base, the latter becoming a hard spurious pericarp. The species are annuals or perennials often with fleshy roots, or shrubs or trees usually articulated at the tnmid nodes, Mirobellia dichotoma, the Marvel of Peru of our gardens, may be taken as the type of the order. M. jalapa was at one time supposed to be the plant, yielding true jalap. This however is a mistake. [Convolvulaceœ.] The roots of the plants of this order are generally purgative. They are natives of the warmer parts of the world in either hemisphere. They are tropical or subtropical. The order is related to Polygonum, Amaranthaceæ, and Cannabinaeœ. It contains 14 genera and about 100 species.
OAKINGHAM, or WOKINGHAM. [Berks.] OAT. [Avon.]

OA. [Avon.]

OATH. The privilege long enjoyed by Quakers, Moravians, and Separatists in giving their evidence upon solemn declaration, is by the Common Law Procedure Act, 1854, extended to all witnesses, who conscientiously object to be sworn. A wilfully false declaration in all these cases involves the party, by the provision of the statute, in the same punishment as perjury. 

OCCUPATIONS OF THE PEOPLE. The importance of obtaining as specific and complete an account as practicable of the pursuits and employments of the inhabitants of this country has long been recognised; and in each decennial census of the present century it has been attempted, with constantly increasing efforts after greater fullness and precision, to ascertain the number and proportion of the persons engaged in agriculture, commerce, the various trades, manufactures, and professions. In the enumerations of 1811 and 1831, inquiries were instituted as to how many families were employed in, or maintained by, agriculture; how many by trade or manufactures; and how many which could not be brought under either of these designations. The answers to these inquiries were given with tolerable fullness. In 1831, it was resolved to ascertain, so far as could be done, the occupation of every male adult twenty years of age or upwards. On that occasion a form, containing a list of one hundred different trades and handicrafts, being those most commonly carried on, was furnished to the overseers in each parish or place required to make a separate return, to be filled up with the number of males aged twenty and upwards; and the overseers were authorised to add to the list such additional trades as were wanted in the printed form. But many anomalies and imperfections arose out of the plan; and it was therefore resolved, in 1841, that the enumerator, instead of using a prepared list of one hundred, or any other definite number of trades, should insert each man's description of himself opposite his name. This led to some curious results. In the more important manufactures, the subdivisions of labour entered in the schedules were so minute, that there were no less than 1282 distinct heads of employment (some of them, it is true, identical) in the cotton manufactures of Lancashire in 1831 the enumerators had entered only 689 for the whole of the country. In like manner, the London occupations, given as 420 in 1831, were 757 in 1841; and the occupations of Great Britain became similarly increased from 3065 to 3777.

In 1851, to use the words of the Registrar-General, to whom the management of the census of that year was entrusted, "it was considered important to extend the inquiry, so as to show, as nearly as was practicable, the number of men, women, and children in every trade and profession," and it was further held to be desirable, notwithstanding the great additional labour entailed in abstracting and tabulating the results, "not only to take out the number of persons of each sex in each occupation, but the numbers at each quinquennial period of age; for without this information the relative salubrity of the professions, and a great variety of important questions, cannot be determined." The results of the inquiries instituted are embodied in a bulky but very able report, drawn up by the Registrar-General, which examines the subject as a whole and in detail from various points of view, and in numerous elaborate tables presents the results as digested after a vast amount of labour and consideration.

We proceed to exhibit some of the results obtained, selecting such as will illustrate various industrial phases of British population.

In looking at the tables with regard to the more general results, there are many interesting particulars which become developable. The total population of Great Britain and the small adjacent islands, is set down at 20,923,477, of whom 10,923,608 are males, and 10,759,899 females. One-half of this total is 10,470,738.

Now this is almost exactly identical with the number (10,418,989) of those domestic servants, or of widows, daughter, grand-daughter, sister, niece, son, grandson, brother, nephew, child under tuition at home, child under tuition at school; that is, persons to whom no occupation whatever is attributed, but who are regarded as dependent on the head of the family for support. Regarded in this light, therefore, just one-half of the population have nothing and do nothing to earn a living; they are the home-members of a family; they may assist in domestic labours, but they do not work at money-getting employments. There are then left half the population, who either possess wealth already accumulated, or exercise their hands and heads in the acquisition of wealth. This is one moiety can, with a near approach to correctness, be divided into five equal parts, thus—

About 1,000,000 domestic servants.
1,000,000 employed in preparing the materials for dress.
1,000,000 employed in making dress.
1,000,000 ordinary agricultural labourers (males).
1,000,000 other persons; male and female, living by farm and field operations.

Most of these numbers are slightly over the million. If we suppose the two millions of farmers, graziers, gardeners, and in-door and out-door farm servants of every kind, to be all employed in raising food (and this is not such a wide departure from the truth as to vitiate such general results as we have now in view) it brings us to this conclusion: of the total population, about 21,000,000, there are—

Of family dependants, having no definite occupation
1,000,000 about one-half.

Of persons supplying dress, food, or domestic service
1,000,000 about one-quarter.

Of persons employed in all other occupations
1,000,000 or more.

When the Commissioners came to prepare their vast tables of the distribution of occupations in the respective divisions, counties, districts, and towns, they had to determine how many different occupations should be given in each table. If the whole 1007 occupations, presently to be adverted to, for males had been tabulated for each and all of the topographical sections, the volumes would have been numerous and bulky beyond all endurance, the labour and expense enormously great, and the practical value very questionable. The list was therefore weeded. Several occupations were omitted which were only very limited in their topographical distribution, and all were omitted in which the total number of persons is very small. Different degrees of minuteness were adopted, according to the nature of the table. Thus, one table, for the whole of Great Britain, gives all the 1007 occupations in alphabetical order, distinguishing the workers who are above and those who are below 20 years of age, but not distinguishing the sexes. Another table, going as low down in classification as sub-classes, shows in respect to these the ratio or percentage of males under 20, males over 20, females under 20, and females over 20: this is done with a view of exhibiting, in a broad and general way, the extent of female labour and of juvenile labour in Great Britain. Lastly, a fourth table, or rather group of tables, gives the occupations of the people in all the 13 divisions of Great Britain, in all the counties, in all the 893 Registration Districts, and in 86 of the principal towns.

We proceed now to give some idea of the nature of the classification adopted.

The primary division, it must be understood, is into 17 groups or classes of occupations, having definite occupations, and these are again divided into 91 sub-classes, rather more than five to a class on an average. Thus—

1. Persons engaged in the general or local government of the country.
   b. Local government.
   c. East India government.

II. Persons engaged in the defense of the country.
   a. Army.
   b. Navy.

III. Persons in the learned professions.
11. In machines.
12. In carriages.
13. In harness.
15. In mines.
16. In implements.
17. In chemicals.

XI. Persons working and dealing in vegetable substances.
1. Vegetable food.
2. Drinks and stimulants.
3. Gums and resins.
4. Timber.
5. Bark.
6. Hemp.
7. Silk.
8. Tobacco.
10. Rice.
11. Sugar.

XII. Persons working and dealing in minerals.
1. Coal.
2. Stone and clay.
3. Earthenware.
4. Glass.
5. Salt.
7. Precious stones.
8. Gold and silver.
9. Copper.
10. Tin.
11. Zinc.
12. Lead.

XIII. Persons engaged about animals.

XI. Persons engaged in art and mechanical productions.
1. In books.
2. In plays.
3. In music.
4. In pictures.
5. In carving and figures.
6. In the making of games.
7. In plans and designs.
8. In medals and dies.
9. In cameras and philosophical instruments.
10. In arms.

The above, it must be remembered, are the 91 sub-classes of male occupations. The sub-classes of female occupations are not quite so numerous, and differ a little (but only a little) in designations.

The 17 classes, or 91 sub-classes are further subdivided into no less than 1072 occupations or employments, giving an average of about twelve to each sub-class, or sixty-two to each class. These are occupations for males only; but there is a separate specification for females, amounting to 746 employments. These are, of course, in some cases identical with those of men, in other cases nearly alike but differently named, while in others they are wholly distinct and form a class by themselves.

Many of the classes cannot be rightly understood until the sub-classes into which they are divided have been examined; and even then, there are two or three against which grave doubts may be urged, as to the principle on which the aggregation of these has been determined. These are classes 9 and 11, and are those here adverted to. This, however, is a matter on which opinions will inevitably clash; for, where offices and employment differ one from another by imperceptible gradations, and where each one may be regarded under many aspects, no one can give a definition which is the classification; we can only adopt a classification, convenient according to the views of him who makes it. The commissioners, for instance, made class 9 to comprise "people who are principally engaged in lodging, entertaining, attending, or providing articles of dress, so as to be brought much into personal contact with those whom they serve." This reads well, in so far as it provides a chain of connection among employments which relate especially to the person; but the sub-classes give it a more satisfactory effect; for, we should expect inns-keepers, coffee-house keepers, eating-house keepers, lodging-house keepers, domestic servants, inn-servers, under-takers, dress-makers, shoe-makers, nursery-maids, rag-gatherers, and washer-women, to be all included in one class, as they are here. Among class 4, we find, the poet, the historian, the painter, the sculptor, the musician, the architect, and the natural philosopher, as well as the professors and teachers of literature and science; while class 11 comprises "those engaged in the higher class of mechanical and chemical arts, intimately connected with artists and men of science, from whom they frequently, either directly or indirectly, derive materials, direction, or inspiration; they multiply copies of original works." Now this analysis has evidently been much studied and elaborated by the commissioners; but it leads to strange results when worked out in detail; for we find the music-master in one class and the musician in another, the painter in one and the engraver in another, the architect in one and the surveyor in another. While publishers, printers, actors, musicians, engravers, carriers, modellers, showmen, civil engineers, pattern-designers, die-sinkers, watch-makers, gunsmiths, machinists, coopers, saddlers, shipwrights, builders, wheelwrights, dyers, scissorers, calenders, and chemical manufacturers, are all placed together in one class.

Taking the 1057 occupations for males, just as they stand in the classified tables, the highest numbers are the following, comprising those exceeding 40,000 persons in each employment:

### Agricultural labourers
1,006,728

### Laboureuse (undefined)
367,472

### Farmers
267,657

### Showmen
243,002

### Farm servants, indoor
235,943

### Cotton spinners and weavers
222,612

### Calenders
216,366

### Carpenters
192,346

### Tailors
135,028

### Blacksmiths
112,154

### Masons
101,351

### Porter and messengers
97,642

### Merchant seamen
89,306

### Woolen spinners and weavers
86,649

### Drawer
78,215

### Gardeners
78,492

### Grocers
68,542

### Butchers
65,912

### Plumbers, painters, and glaziers
62,421

### Carpenters and joiners
56,252

### Bakers
55,663

### Websters and spinners and weavers
51,963

### Engineers and machine-makers
40,030

### Silk spinners and weavers
34,169

### Clerks (commercial)
34,741

Among females, of 80 years of age and upwards, the highest numbers placed opposite definite occupations are the following:

### Domestic servants (general)
401,850

### Milliners
292,437

### Cotton spinners and weavers
234,212

### Women and maidservants
136,382

### Farm servants, indoor
76,388

### Out-door
56,067

These numbers, however, must not be used for any inferential purpose, without taking others belonging to employments very nearly connected with them. Thus, the 401,950 general domestic servants do not include about 200,000 others who enter themselves under the special designations of housekeeper, housemaid, cook, nurse, and inn servant; the 50,942 general milliners does not include the 89,504 and 67,504 and 29,000 needlewomen and needlewomen of other kinds; and so in other cases. It must also be borne in mind, in respect both of the male and the female lists, that the highest numbers are attached to designations which are rather degrees of relationship than occupations in a strict sense, we are told.

Wives (not otherwise specified)
2,631,380

Children and relations at home, ditto
4,745,217

Children who attend school, ditto
2,752,787
Here we have at once more than a third of the entire population entered under three headings, excluding everything like a business designation.

As a summary of results relating to occupations generally, without regard to age, sex, or topographical direction, it may be added, applicable to the manufacturing table, containing the Commissioners' own enumeration of the number of persons employed in 108 avocations in Great Britain, comprising all those for or in respect of which the numbers exceed 10,000: more domestic relationship, such as 'wife,' 'widow,' &c. is not here taken into account; all such domestic occupations, in the usual meaning of that word—male or female, adult or juvenile.

Occupations in Great Britain, and Number of Persons Engaged in them (arranged in the order of the Numbers), in 1851:

</tbody>
</table>

Leaving these general results, which apply for the most part to the whole of Great Britain, and to the whole circle of occupations, we proceed to notice a few of the results having a somewhat more special character. One of these has relation to the employment of the many by the few, and another to farms, farmers, and tenant farmers.

One of the valuable results of the Census of 1851 is the determination, to a certain degree of correctness, of the relative positions of employers and employed; a classification of masters and men in giving occupation. The Commissioners were imperfectly filled up; but the general result approximates on the whole pretty nearly to accuracy. We may solve many interesting questions by means of the tables thus produced. For instance, let the question be this—How many occupations are there in which some of the masters employ 350 hands or more? They are the following:—shoemakers, glovers, stockers, weavers, engine and machine makers, builders, carpenters, distillers, drapers, corn dealers, criminals, and manufacturers, in the usual meaning of that word—male or female, adult or juvenile.

It is in Lancashire chiefly that the factories are situated in which the largest number of persons are employed. This might be expected, knowing, as we do, on how gigantic a scale the cotton-mills of that county are conducted. No less than 106 of the Lancashire mills employ more than 350 hands each; how much more, is not stated in detail. There are also 100 others in the manufacturing counties, of which the number is at least 350 work-people.

In London the number of work-people employed by the respective masters differs, of course, from that observable in country lists, since the predominant trades there are in a different state. Taking 100 as a minimum, it may be asked,—Which are the London trades comprising the greatest number of masters who employ 100 men or more each? We find that there are altogether 86 such masters—a smaller number than might at first perhaps have been supposed. Of these, there are 22 builders, 6 engineers, 5 shoemakers, 5 printers, 4 painters and glaziers, 3 piano-forte manufacturers, 2 of bookbinders, gunsmiths, masons, tanners, silk manufacturers, drapers, tobacco manufacturers, and similar persons. It may be added, that in this metropolis, there is not one entered with so many as 50 men in his employ; among distillers and rectifiers, not one with so many as 20; evidently there are great omissions here. Again, when we find that there are only 8 vineyard makers, 3 dye manufacturers, 1 lawyer, entered as employing any persons at all, it is still more manifest that many of these returns were incomplete. The explanation is doubtless to be found in the statement prefixed to the Tables: 'Many of the returns were, in fact, so incomparably short that we had directed the whole number—omitted to attend to this instruction (directing that the master is to be distinguished from journeyman, and that the number of persons in the employ of the master is to be added, not to their own, but to all the others, or the number of hands employed in particular trades, as carried on in London. This may be generally the case, and accordingly we have directed the attention, are sufficient to show that great caution is necessary in drawing deductions, as in some cases they would certainly be by no means just ones.

The small tradesmen in the metropolis are, in many respects, the best customers of all, on account of their large number. The small chamber-masters, or small shopkeepers who employ each not more than two journeymen, or two apprentices, or one journeyman and one apprentice, are surprisingly numerous, showing how to great a degree master-
ship is diffused in the metropolis. We give the following table of chief trades followed by Masters who employ 1 or not more than 2 Journeymen or Apprentices.

<table>
<thead>
<tr>

<td>842</td>
<td>640</td>
<td>644</td>
<td>588</td>
<td>224</td>
<td>242</td>
</tr>
</tbody>
</table>

The table is to be understood thus: that in the above eight occupations there are 3163 masters in the metropolis, who employ either one or two persons each. Of those, still lower in the social scale, who claim mastership only over their own individual labour, the numbers run in a somewhat different order, beginning with a shoemaker (the 'cobbler who lives in a stall') and, perhaps, going thence to the tailor, the butcher, the baker, the grocer, the carpenter. But these numbers include also those masters who made no definite returns at all.

In respect of agricultural pursuits, the Commissioners sought to obtain a return of the number of farms, the size of the farms, and the number of persons engaged in them. The following is a convenient general outline of the result:

<table>
<thead>
<tr>
<th>Size of Farms</th>
<th>Number of Farms</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acres</td>
<td>Great Britain</td>
</tr>
<tr>
<td></td>
<td>England and Wales</td>

</tr>
<tr>
<td>700-800</td>
<td>2,132</td>
</tr>
<tr>
<td>and upwards</td>
<td>38,849</td>
</tr>
</tbody>
</table>

Besides the above, there were 2956 farms of which the sizes were not stated in the returns; making 265,836 farms or farm-holdings altogether. It is found that large farms prevail most in the North, and in Norfolk and Suffolk. The average size of all the farms is 102 acres; and, taken in the aggregate, they occupy just about one-half of the territory of Great Britain. Two-thirds of the farms are less than 100 acres each in extent. About 9000 small farmers seem to have no labourers except the members of their own families; about 30,000 farmers employ more than 60 labourers each; while all the rest have in their service a number varying from 1 to 60.

Professional avocations, as distinguished from trading and manufacturing, are now being created facts, which may be put together in the following form:

<table>
<thead>

</table>

As before noticed, there is more confusion between Class 4 and Class 11. In the list here given, although artists are exclusively of the latter, but not singers or dramatisers are, but not actors. In order, therefore, to make our enumeration somewhat more complete, we must bring in a few items from Class 11, still comprising them among "persons engaged in literature, fine arts, and sciences."

</table>

But the total of the Queen's forces, at home and abroad, naval and military, officers, &c., was 220,000.

It is necessary to bear in mind that many dissenting ministers are, in the Census returns, entered under the occupations which they follow during the week.

Persuaded in respect of the numbers engaged in various professions. The Census Reports are those which establish a comparison between different parts of the country. Large generalisations may be made from the tables which relate to the whole of Great Britain; but for comparison and analysis, the sectional tables will have a peculiar value of their own.

In reference to a particular department of occupation, or a particular social relation, we may wish to know how far England, and Scotland, and Wales, differ from one another in characteristics; in what way the 40 English Counties, 12 Welsh Counties, and 32 Scotch Counties exhibit peculiar characteristics; by what peculiarities the 19,149 registration districts or post-office unions of England and Wales are distinguished; and so forth. The voluminous Census tables afford a store of information on all these local details.

Of course, when different districts or portions of the kingdom are treated separately, the metropolis comes in for the first notice; the following, then, is a rough outline of employments generally in the metropolis. Confining our attention, at present, to males, and to males only of 20 years and upwards, we have the following:

- 5,466,815 males of 20 years and upwards in Great Britain, 632,545 live in the metropolis; that the London shoemakers number 26,639, and the London tailors, 20,527; that there are no fewer than 25,708 domestic and inn servants; that the commercial establishments are so numerous and so extensive as to employ 15,135 clerks and travellers; that the coachmen, drivers, carriers, waggoners, draymen, and others who drive vehicles through the London streets, number more than 17,000, besides 14,000 messengers and porters, in addition to railway, canal, and river servants; that there are, for housework, 21,174 carpenters, 13,817 painters and glaziers, and 16,038 bricklayers and plasterers; that among those who supply us with food and drink, are 9841 bakers, 7455 butchers, 3878 drapers, 6473 grocers, 3612 mill-sellers, 3235 greengrocers, 2923 fishmongers, and 2156 cheesemongers; that the leather trades, chiefly in Bermondsey, employ 5391; that there are 13,906 persons employed in printing, binding, and selling books; that the wood-furniture makers and sellers number 13,574; and that there are more than 40,000 labourers whose branch of labour is undefined, but who must be distinguished from skilled artisans.

Let us next, still confining our attention to the metropolis, glance at the female occupations in a similar way. Among the 9,093,646 females, aged 20 years and upwards, employed in Great Britain, 768,418 are in London. Of this number, 316,517 designate themselves simply as wives, and 65,677 simply as widows, and about 40,000 as daughters, without any reference to the particular occupation. But of those who appear to earn their living by the labour of their own hands or brains, there are no fewer than 116,666 domestic servants of various
kinds, 73,620 needlewomen of various kinds, and 45,764 charwomen, washerswomen, and manicures. These, with 50,181 housemaids, constitute a class of domestic servants, which comprise all the large items among the female adult population of the metropolis; all the other items are, individually, very small. These facts are not without their instruction; for they show how limited is the range of female employment in London, and how large is the number of independent and self-supporting females, those who are dependent on relations for support, and those of independent means, there were 330,000 adult females in London in 1851 dependent on their own exertions for their daily bread also, and they show also how a large number of families in comfortable circumstances in London, to give employment to nearly 130,000 female servants, and 45,000 laundry- and char-women.

The census returns, therefore, how far a differential principle seems to determine the distribution of occupations. We take the cotton-spinning county of Lancashire. Here we have 550,076 males of 20 years of age or upwards, against 1,182,000 in the metropolis; that is, in the ratio of about 55 to 100. Different indeed, however, is the ratio in regard to employment. We have seen that the metropolis contains about 26,000 male adult servants, 31,000 drivers and porters, 27,000 shoemakers, 21,000 carpenters, 20,000 tailors, 12,000 bricklayers, 10,000 coachmen, and 20,000 in Lancashire, these eight occupations exhibit the numbers 4708, 9127, 15,443, 12,146, 11,346, 7658, 7643— all far below the ratio in respect to total inhabitants. In London there are 33,000 persons in the public service, receiving contributions from the common funds; whereas in Lancashire there are only 11,000. In London there are 24,000 professional men, engaged in divinity, law, physic, science, and fine arts; in Lancashire the number is 11,000. In London there are 14,500 persons employed in writing, printing, binding, and selling books and periodicals; in Lancashire there are 2,000. All these numbers, it is evident at a glance, differ widely; London having far more than its ratio of 100 to 86 in each of these employment. But let us examine each of the classes more closely, and we shall find Lancashire takes precedence of the metropolis. Of course, in a county, farmers, graziers, shepherds, gardeners, agricultural labourers, and so forth, must be relatively more numerous than in a city; and thus we need not be surprised to find 65,000 of these in Lancashire, against 14,000 in the metropolis. And, considering the wonderful shipping activity of Liverpool, and the numerous canals which traverse Lancashire in every direction, we may be prepared to expect that the shipping and the marine is a more numerous class in the numbers of persons connected with ships, boats, and barges in various capacities; in the metropolis, this number is about 21,000, in Lancashire 18,000—very nearly, indeed, in the ratio of 100 to 85. But it is in textile manufactures, and also in mining, that Lancashire most readily takes the lead before London. In Lancashire there are 104,000 persons (out of about 540,000) engaged in various departments of the cotton manufacture, against a few hundreds in London; 7000 in woolen manufactures, against a few hundreds; 21,000 coal miners and labourers, against 5000; 4000 quarrymen, against 500.

Here it must be borne in mind, that the numbers in the preceding paragraph are of males only, and males too who have reached their 20th year or upwards. A few parallel entries will suffice, relating to certain occupations for adult females: of domestic servants and nurses there are, 132,000 in London, and 55,000 in Lancashire; of silk-workers, 8000 in London, and 12,000 in Lancashire; of cotton-workers, 1000 in London, and 50,000 in Lancashire. Here we find that one-sixth of all the adult females in London are domestic servants or nurses, and that one-sixth of all the adult females in Lancashire are engaged in the cotton manufacture.

There are also striking differences in respect to juvenile labour:—The metropolis contains 474,013 males, and 493,260 females, under 20 years of age; the numbers in Lancashire are 489,749 and 474,735 respectively. Now in the metropolis, Whitechapel and Poplar are the places where not only in their domestic or family relations, without connection with any particular employments, there remain about 200,000 who are considered to have some occupation or other; whereas in Lancashire there are 270,000 having employment; and out of this number about 120,000 are employed in the cotton manufacture alone—that is, 120,000 young persons.

In the metropolis, on the other hand, young seamstresses and young domestic servants chiefly fill the list.

We have seen London had 5,223,226 inhabitants, there are, in round numbers, 630,000 men, 760,000 women, and 970,000 persons of both sexes under 20 years of age. Of this latter number, nearly 300,000 are under 5 years of age, and therefore almost equally divided between males and females. In order to show, then, how far male employment are to be met with in London for young persons, we give the following table in relation to a few occupations:—

<table>
<thead>
<tr>
<th>Occupation</th>
<th>Under 20</th>
<th>20 and upwards</th>
</tr>
</thead>
<tbody>
<tr>
<td>Law clerks</td>
<td>1,430</td>
<td>4,401</td>
</tr>
<tr>
<td>Teachers</td>
<td>1,047</td>
<td>3,437</td>
</tr>
<tr>
<td>Messenger and porters</td>
<td>19,743</td>
<td>13,741</td>
</tr>
<tr>
<td>Printers, &amp;c.</td>
<td>3,518</td>
<td>13,306</td>
</tr>
<tr>
<td>Silk manufacturers</td>
<td>1,145</td>
<td>5,529</td>
</tr>
<tr>
<td>Cabinet-makers</td>
<td>2,561</td>
<td>13,953</td>
</tr>
<tr>
<td>Gold and silver work</td>
<td>1,145</td>
<td>6,419</td>
</tr>
<tr>
<td>Brass work</td>
<td>1,062</td>
<td>5,528</td>
</tr>
<tr>
<td>Iron work</td>
<td>770</td>
<td>5,901</td>
</tr>
<tr>
<td>Building trades</td>
<td>6,981</td>
<td>39,843</td>
</tr>
</tbody>
</table>

It is probable that the greater part of the above young persons are apprentices, although the returns do not specify this fact in words. The 19,743 young messengers and porters are evidently the "errand boys," rather a formidable body in London. Taking female occupations instead of male, we thus notice the prevalence of age in a similar manner, we find the following:

<table>
<thead>
<tr>
<th>Occupation</th>
<th>Under 20</th>
<th>20 and upwards</th>
</tr>
</thead>
<tbody>
<tr>
<td>Teachers</td>
<td>1,514</td>
<td>11,185</td>
</tr>
<tr>
<td>Servants</td>
<td>46,324</td>
<td>136,292</td>
</tr>
<tr>
<td>Needlewomen</td>
<td>4,998</td>
<td>11,184</td>
</tr>
<tr>
<td>Silk-workers</td>
<td>2,375</td>
<td>8,847</td>
</tr>
<tr>
<td>Paper-workers</td>
<td>625</td>
<td>1,123</td>
</tr>
</tbody>
</table>

If we were to name the three most characteristic kinds of occupations in London for males under 20 years of age, therefore, they would be apprentices to mechanical trades, errand boys, and junior clerks; and for females under 20 years of age, they would be servants, needlewomen, and teachers.

The 36 districts of London exhibit many remarkable groupings in reference to employment. It is well known that the members of a particular trade are wont, in many cases, to congregate near each other; but the Census tables show this more exactly. Lawyers live in Kennington district in greater relative numbers than in any other district—a fact for which there is a very good reason. The population of London is, in the ratio of 100 to 85, but the number of lawyers is, in the ratio of 100 to 26. This is because not only are there more lawyers in London, but there is a very much larger number of the higher learned professions. The same results are shown in other districts. In Kennington, there are more lawyers than in any other district. It is true that in the districts of St. George's Hanover Square, St. James's Westminster, Marylebone, and Kennington, the lawyers are the chief districts. Domestic servants are found in greatest relative force in the districts of St. George's Hanover Square, St. James's Westminster, Marylebone, and Kennington—indeed overwhelmingly so. The tailors are strong in St. James's, Marylebone, and St. Pancras; but relatively more in the Whitechapel and neighbouring districts, where much of the slop work is done. The chief districts for shoemakers are St. Pancras and Marylebone in the north, Lambeth and Newington in the south, Whitechapel and Bethnal Green in the east. The gardeners have Kennington and Wandsworth as their chief districts. Beyond all other districts, the City is the locality for publishers and book-sellers, for it contains the regions of Paternoster Row, and the numberless courts around Fleet Street. Musical instrument makers congregate in decided preponderance in St. Paul's. There are two districts in which watchmakers appear in surprising force; these are, as may be supposed, Clerkenwell and St. Luke's.Coach-makers in Pimlico and Marylebone; shipbuilders in Brixton and Poplar; dyers and calenders in Shoreditch and Bethnal Green (where the silk manufacture is carried on); leather workers in Bermondsey (nearly as many as in all the other 35 districts combined); sugar refiners, nearly all in St. Sepulchre, Whitechapel, and Limehouse; cabinet makers, furnitur makers, Pancras, and especially Shoreditch; cooper's, in the districts nearest the various docks; rope and sail makers, Stepney and Bethnal Green; workers in gold, silver, and precious stones, Clerkenwell—these are the chief associations between occupations and districts.

And so, in like manner, are there certain occupations for...
adult females, which seem to be carried on in some districts rather than others. Domestic servants and governesses are, relatively to the male, most numerous in the districts of Keestington, Marylebone, and St. George's in Hanover Square; while schoolmistresses, as distinguished from governesses, are relatively as numerous in other districts. The char-
women are especially numerous in Marylebone. Those who assist in the shops are chiefly employed in Southwark and Bermondsey, where most of the hat factories are situated. The women tailors, who make waistcoats and cheap goods for the shop shops, are chiefly in the three
examples towns, Whitechapel, and St. George's in the East. The milliners, as distinguished from seamstresses, are in greatest number in Marylebone and Pancras; but the seamstresses, who are understood to occupy a lower grade among needlewomen, are in strongest force in Spieyey and St. George's in the East. These and the tailors in the Marylebone
chiefly. The washerwomen and manglers take up their abode chiefly in the genteel districts. The women who work at shoemaking live principally in Shoreditch and Bethnal Green; while the umbrella makers are rather to be found in Whitechapel and St. George's in the East. The hawker and pedlars are chiefly in the four districts just named. Artificial flower-makers in St. Pancras; silk workers in Bethnal Green; upholsterers in Marylebone; lace workers in the same district—are other examples of predominance.
For reasons already sufficiently indicated, it will be impossible to give abstracts of the county and district tables here; so numerous are they, and to so great a length is the classification extended. But we are able to select a few examples sufficient to illustrate broad general principles of industrial distribution. For instance, every one knows that certain towns have become celebrated for certain manu-
factures; Sheffield for cutlery, Birmingham for small metal works, Manchester for cotton, Leicester and Notting-
ham for hosiery, Leeds for woollens, Bradford for stuffs, and so on; but it may be useful and instructive to know more exactly the extent to which this localisation is carried. Again, certain districts containing no very
large towns, but in which some particular manufactures are nevertheless carried on to a remarkable extent; such as straw-plait, pillow-lace, needles, and many others.
Passing in review the principal cities, boroughs, and towns, we can readily determine from the tables, even without the aid of any previous knowledge on the subject, the prev-
malling character of the industry in each town, and to some extent the degree in which female labour and juvenile
labour are made use of. Let us take a few of the towns in succession.

Birmingham.—Here the males under 20 years of age are 52,640, and above 30 years 61,276; the females under 20 are 33,380; above 30 years 55,545; so placing the numbers in a compact table, we have the result thus:

<table>
<thead>
<tr>
<th>Males</th>
<th>Females</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>52,640</td>
<td>33,380</td>
<td>85,020</td>
</tr>
<tr>
<td>61,276</td>
<td>55,545</td>
<td>116,821</td>
</tr>
</tbody>
</table>

116,821 + 118,293 = 235,141 total population.

Now in respect to their population, we find that out of the various classes of occupations, classes 11 and 14 are those in which the Birmingham inhabitants are chiefly employed—viz., working in metal. 1800 men making guns, 1200 making machines and tools, 2400 working in gold and silver, 3000 brass founders, 1400 button makers, 1800 wheelwrights, and 1200 iron founders and makers. These are among the men of 50 years and upwards; but of the males under this age there are no less than 7000 employed in the few metal trades above enumerated. In Birmingham, females are largely employed in the smaller kind of metal manufactures; example—1200 young females, and 1,800 adult females in making buttons; and 300 and 1,800 in miscellaneous iron and steel works.

Birmingham—cont. In these cotton towns are

<td>120,821</td>
<td>225,787</td>
</tr>
</tbody>
</table>

191,457 + 208,864 = 400,321 total population.

These are within the Parliamentary limits, which exceed

the municipal. Now passing over the tailors and shoe-
makers, the carpenters and painters, the bakers and butchers, who in all these towns must necessarily form a considerable part of the population, we turn to class 13 as likely to exhibit remarkable characteristics of the workers in Manchester and Salford. Here one single entry, cotton manufacture, com-
prises employed numbers—12,107 men, 9052 boys, 14,503 women, 9051 girls making total of 47,333, in which the females exceed the males by 22,554 against 18,949. Put-
ting the whole of the textile manufactures together—relating to cotton, flax, silk, and wool, they appear to employ about 32,000 men, 13,800 boys, 20,000 women, and 19,000 girls, exhibiting the remarkably near equality of 33,000 males to 32,000 females—more than a quarter of the total population of Manchester and Salford employed in making the textile ma-
ferials for drays, besides 12,000 tailors and seamstresses em-
ployed, would make the total in this branch of the work about 1,700. We have in this paragraph, for brevity, applied the terms boys and girls to young persons under 20 years of age; and shall do so in those which follow.

Nottingham.—Here we enter a bobbin-net and cotton
stocking town—

<table>
<thead>

<td>16,074</td>
<td>30,879</td>
</tr>
</tbody>
</table>

26,587 + 30,829 = 57,407 total population.

Of course the numbers in any particular occupations here will appear much smaller than in Manchester, because the population is only one-seventh as large; but the following entries are well worthy of note—stocking-makers, 3,469 men, 412 boys, 1,068 women, 474 girls, making nearly 6,000 in all; boot and shoe manufacturers, 1,245 men, 264 boys, 977

wants women, 1,902 girls, exhibiting a still more striking total of

more than 7,000 persons. Of the aggregate 12,000, more than 7,000 are females. It is worthy of notice that the hose and lace workers bear a larger ratio to the population of Nottingham, than the whole of the textile workers bear to the population of Manchester.

Manchester.—We quit hosiery and lace, to turn to iron and coal —

<td>35,023</td>
</tr>
</tbody>
</table>

34,007 + 29,071 = 63,078 total population.

Now in this remarkable town we glance over the classes of occupation, one after another, without meeting with any numbers so large as to arrest the attention. At last, however, in class 14, we encounter them in surprising force. There are 25,000 miners, comprising 'coal miners, 17,071 boys, and 4,303 men; and among iron works, 3,902 men, and 6,916 women; making a total of about 15,000 workers in these two minerals alone; these, with 700 or 800 females similarly employed, comprise a quarter of the entire population. Con-

siderably more than half the adult male population of

Meryth Tydvil are workers in iron and coal, employed chiefly in the four great establishments of Dowlands, Cyfarthfa, Pen-y-darren, and Plymouth works.

Bradford.—This busy Yorks town introduces us to a wholely different class of manufactures. The parliamentary

borough is somewhat extensive, and includes some of the neighbooring villages, comprising a population of—

</tr>
</tbody>
</table>

49,096 + 53,912 = 103,008 total population.

After making allowance for the large number of tailors, shoemakers, carpenters, masons, and similar handicraftsmen for supplying the wants of so large a population, we find that class 13 contains the employments characteristic of Bradford, who is so well extended, under the cotton

manufacture, 5351 boys, 10,759 men, 7936 girls, and 6780 women—4,000 of the whole population employed in worsted and stuff manufacture alone. The woollen cloth, the silk, and the cotton manufactures, occupy perhaps 1000 altogether, showing how insignificant they are at Bradford.
which certainly appears surprisingly large. Aberdeen is also engaged in these trades, but in a very much smaller ratio than Dundee.

These few examples would perhaps suffice to illustrate the distribution of particular branches of manufacture in the principal towns; but, adopting a still more compressed form, we will give a few additional instances in the following way:

At Portmouth, out of about 35,000 men and boys in the borough, about 9000 are in the public service, and receive pay from the community; while there are about 2000 privately employed as seamen or as shipwrights. At Leicester, out of 20,000 males and females, about 10,000 are engaged in worsted stockings, and similar articles. At Northampton, out of 13,000 men and boys, more than 4000 are employed in making boots and shoes, the staple industry of the place; and at Stoke-on-Trent, boys similarly employed are in the ratio of one to four of the whole population. At Worcester, out of 16,000 women and girls, 2133 are employed in making gloves. Of the 25,705 men and boys in Wolverhampton, about 7300 are employed upon metals or upon coal; no less than 14,000 make locks alone. In Dudley the ratio is about as high, about 6000 out of 19,093.

Covenry is remarkable for two trades, about as diverse as any two can be, ribbon-making and watch-making: out of a population of 56,121, nearly 10,000 persons (of whom 6000 males and 4200 females) are engaged in silk and wool manufactures, and we have 1700 men and boys who are making watches. At Stockport, 17,000 persons are employed in cotton manufactures, out of a total population of 53,535—nearly one in three; at Blackburn, 6000 out of one in three; at Bolton, 14,000 out of 61,171; at Oldham, 20,000 out of 73,207; at Preston, 18,000 out of 69,542. Thus, in these five cotton spinning and weaving towns, containing an aggregate of about 380,000 inhabitants, about 34,000 males and 42,000 females are engaged in many more than one-fourth of the inhabitants—employed in making and weaving cotton, and in cotton manufacture; and these numbers are out of 31,000 inhabitants, nearly 9000 are employed in various kinds of textile manufacture, of which the principal is woollen.
shire we almost entirely lose the lace-trade; but the straw-plait employs about 9000 females out of 87,497. In Cambridgeshire there is a little done in these two trades, but only 2660 females are employed. In Worcestershire, on the other hand, the females out of 30,295 engaged in the lace-trade. In these two departments of cottage industry, the females employed are of all ages from 0 to 90, chiefly between 10 and 30.

Worcestershire, for instance, in the manufacture of black and white worsted, is not in the direct manufacture. It is principally a forest of the needle manufacture. At Redditch in this county nearly all the inhabitants are supported, directly or indirectly, by this manufacture; although the steel for making the needles, and all the coal for heating the stoves and engines, must be bought from other quarters.

Cornwall is rich in metals, but has no coals. It has 172,193 males in the (registration) county. Among these are 3000 seamen and 2800 fishermen; but when we come to class 14, mineral working, we find about 16,000 copper-miners below 10 years of age, and about 6000 employed in other ways on metals and minerals; none, however, in coals. There are also about 6000 females engaged at the 'above-ground' works of the copper and tin mines.

Let us contrast this with a county containing much coal but little metal. Durham (registration) county contains 207,088 males, and 204,681 females, a departure from the general rule; for here we find more males than females. New Durham was a county of boys and girls and navigation; a very large number out of such a population, and evidently due principally to the navigation of colliery vessels. The number of 4600 ship and boat builders is also large, and points to the small trade of Sunderland. But a much larger number is engaged in coal-mining and working, about one-seventh of the male population. In Northumberland, as might be expected, a somewhat parallel state of things presents itself. There are here 148,016 males; and, of these, about 6000 are engaged in navigating ships and boats, 1400 in building ships and boats, and 11,000 coal-miners; the parallelism, it will be observed, is in the nature of the prevalent occupation, and not in their extent, for Durham greatly takes the lead in this respect; Northumberland is more a county of forgers than of navigators, as being upwards of 50 years of age; but it is satisfactory to find that, consequent on recent legislation, scarcely any boys under 10 years of age, or females of any age, are included among the coal-miners or labourers.

There are two counties in the western part of the kingdom which we may similarly notice, in respect to the manufactures, but still more decidedly to coal-mining. These are Monmouthshire and Glamorganshire. Monmouthshire has sources and springs and mining—there is, for example, in a mining county, of the males outnumbering the females. The iron trades occupy 12,000 males, and the coal trade also 12,000—in round numbers: together more than 24,000 males are engaged. Females are not much employed in these trades in this country. Only Glamorganshire, containing the remarkable towns of Merthyr and Aberdare and their vicinity, has a population of 126,057 males and 115,600 females. Of these males, no less a number than 16,500 are engaged in the coal trade, and 14,000 in the iron trades. In another Welsh county, Caernarvon, copper manufactures are, in respect to the population, if not as remarkable as iron manufactures in Glamorganshire, at least worthy of note as the staple industry of portions of the county. The explanation of this is, that nearly all the copper ores of Cornwall and Devon are sold on the spot to copper-smelters, who have their works at Swansea or Neath, or some other town in Caernarvonshire. Besides the copper workers there are, among the 126,057 males in this county, 14,000 workers in iron, and 15,000 coal-workers.

Something has been said, in former paragraphs, of the remarkable distribution of employments in the cotton and woollen towns of the north; and a comparison, in relation to certain items, both of the trade between Lancashire and Yorkshire and this capital, will be attempted hereafter. In Lancashire, out of 1,005,824 males of all ages, there are about 160,000 engaged in various departments of wool and worsted manufactures; and out of 673,159 females, about 80,000 similarly engaged; and of this total of 240,000, about 17,600 are under 10 years of age. In the West Riding, out of about 87,497 males, not less than 118,000 are under 20 years of age. In the West Riding of Yorkshire, out of 666,918 males of all ages, there are about 120,000 engaged in various departments of wool and worsted manufactures; and out of 763,159 females, about 50,000 similarly engaged; and of this total of 220,000, about 8000 are under 10 years of age. From the above numbers, we observe the following results:—that the male workers in wool bear a larger ratio to the whole male population in the West Riding, than the male workers in Lancashire; and that the number of females engaged in cotton manufactures, about 1 in 6 of the West Riding population is engaged in the wool manufacture.

Such are a few of the most striking results obtained by the Census of 1851, relating to the occupations of the people. There are, however, a few words in conclusion, for any person who desires to know something more of the condition of the people, in this hard-working country, than can be derived from vague generalizations and partial inquiries.

OCEANIA, a name given by Buffon and other French geographers to a fifth division of the earth. They make it extend from about 35° E. to 105° W. long.; the northern boundary being the Indian Ocean, Malacca Strait, the Chinese Sea, and the Pacific along the parallel of 33° N.; the southern one from the strait of Magellan to the extremity of Tierra del Fuego.

A name is thus made to comprise the Andaman Islands, all the islands of the Indian Archipelago, Sumatra, Java, Borneo, Celebes, the Moluccas, the Philippines, Formosa, Australia, New Guinea, New Zealand, and the waters of the Pacific within the limits above stated to the islets of Sala-y-Gomez, the most eastern of the whole.

O’CONNELL, DANIEL, the eldest son of Morgan O’Connell, was born at his father’s residence near Cahir, county Tipperary, Ireland, August 6, 1775. The family of O’Connell, or O’Connell, is of antiquity in the south of Ireland, but the circumstances of the father of Daniel O’Connell were much straitened. Still he did not neglect the education of his son, and his instead of his means, for he sent him at an early age to a "poor old hedge-schoolmaster," named David Mahoney, who first taught the Irish agitator his letters. At the age of thirteen Daniel O’Connell was removed to a school at Redington, near Croy, county Cork, kept by the Rev. Mr. Harrington, a Roman Catholic priest; this school is said to have been the first publicly opened in Ireland after the repeal of the penalizing laws which made it penal for a Roman Catholic to educate his children. In 1790 Daniel, then a schoolboy of fifteen, was awarded a prize by the Lord Chancellor for an essay on the principle of intention of being sent to Lodge; but on reaching that place he was found to be too old for admission, and accordingly was entered at St. Omer’s. There he remained till 1793, when he was transferred for a time to the English college of the Blue Coat School in London, and thence was sent to St. Omer’s, he rose speedily to the head of the college; and so arrested the attention of the then president, Dr. Stapyton, that he persuaded him that he would hereafter make a remarkable figure in the world. The first outbreak of the French revolution scattered the scholars of the Roman Catholic colleges at Donaj and St. Omer’s. Daniel O’Connell succeeded in reaching Calais safely, and, embarking on board the English packet-boat, he landed on the shores of England, "half a Tory at heart"—so deep and keen was the impression left upon his mind by the excesses of the revolution in France.

The legal profession having been recently thrown open to members of his faith, he in 1794 entered himself at Lincoln’s Inn; and four years afterwards was called to the bar, having taken no ordinary pains to qualify himself. His first public speech was against the proposed union between the English and Irish legislatures. It was delivered at a meeting of the Roman Catholics of Dublin, assembled at the Royal Exchange in that city, for the purpose of petitioning against that measure; but the meeting was broken up by the intervention of the military. In 1802 Mr. O’Connell, while he was an active member of the House of Commons, was married privately to his cousin Mary, the daughter of Dr. O’Connell of Tralee. The calamitous occurrences however connected with the Irish outbreak of 1803, known by the name of Emmet’s rebellion, found Mr. O’Connell already in possession of a moderate practice. He had been becoming gradually absorbed in the arena of political con-
tention. Emmet’s trial was the starting point of a new era in the history of Irish agitation: the cruelty inflicted by the citizen-soldier made an impression as deep and lasting as it was general, and the ‘Catholic Question,’ as it was called, rose daily in importance. From this time forward Mr. O’Connell took the leading part in the prosecution of the Roman Catholic cause, and in the 14th of November, 1828, he writes to the late Lord Shrewshury, ‘before the passing of the Emancipation Bill, the burden of the cause was thrown upon me. I had to arrange the meetings, to prepare resolution after resolution for the, consideration of the House of Commons, in the case of each person complaining of practical grievances, to remove the torpid, to animate the lukewarm, to control the violent and inflammatory, to avoid the shools and breakers of the law, to guard against multiplied treachery, and at all times to be ready to meet the real or fancied enemies of the cause.’ Day and night he devoted himself with surprising energy to the work, without receiving pay or fees. In 1804 the ‘Catholic Board’ was dissolved by a proclamation from government, but it was immediately revived under the name of the ‘Catholic Committee.’ It met in the Exhibition House in William-street, and its debates were reported from January 1805.

In 1818 Mr. O’Connell fought a duel with Mr. J. A’Estre, and was severely wounded in the leg. He afterwards, in consequence of the effects of the wound, fell into an aggravation and exacerbated state, and inflicted on his adversary a wound which ultimately proved fatal: it is but just to add that for this result he over-wardsfelt and expressed the most painful remorse. Mr. O’Connell’s public life henceforth offers very little material for comment, and the year 1832, which was the period of the Roman Catholic Emancipation Bill being carried. In the summer of 1828, when the fever and excitement on the subject then in suspense was at its height, Mr. O’Connell and his friends judged that the time was come for bringing the question to a final decision. In the June of that year a vacancy occurred in the representation of Clare county, and Mr. O’Connell, though a Roman Catholic, was proposed as a candidate against Mr. (afterwards Lord) Fitzgerald. He was returned victorious by a large majority, and when the Westminster seats were taken his seat in St. Stephen’s. As a Roman Catholic, he of course refused to take the oaths drawn expressly against the doctrines of the Roman Catholic Church. Discussions in the house, and arguments at the bar, ensued; and though the session closed without any practical result, yet the agitation in Ireland began to assume a formidable appearance, and to threaten another outbreak. Alarmed at the probable consequences of further opposition to claims which a large majority of educated men regarded as just, the Duke of Wellington and Sir Robert Peel gave way, and early in the following year brought into parliament a bill for the repeal of the last civil disabilities under which the Roman Catholic Church and the Roman Catholic population were classed and took his seat as member of parliament in May 1829. In the following year, at the general election occasioned upon the death of George IV, Mr. O’Connell exchanged the representation of Clare for that of his native county, and returned with a majority of several thousand, which was unassailed and unshaken. He represented Dublin from 1822 to June 1835, when he was unseated on petition, but was immedi-ately afterwards returned for Kilkenny. In 1837 he was once more returned for Dublin, and in 1841 for the county of Cork. To carry on more effectively the agitation, Mr. O’Connell had relinquished his professional practice and as a compensation for his loss of income, an annual subscription was organised, which afterwards came to be known as the ‘Rent.’

The year 1843 witnessed the return of Sir R. Peel and the Conservative party to power, and this was the signal for renewed agitation in Ireland. In the following year, Mr. O’Connell commenced his movement in favour of a repeal of the Union, which met with general sympathy from the vio- lence of the movement, and the ignorance of his professed and an annual subscription was organised, which afterwards came to be known as the ‘Rent.’

In 1843 monster meetings were collected on the royal hill of Tara, on the Curragh of Kildare, the rath of Mullaghmast, and other localities renowned in tradition and song. A monster meeting announced as to be held on Connaught, and the ignorantibus his profession and an annual subscription was organised, which afterwards came to be known as the ‘Rent.’

Mr. O’Connell was convicted of sedition, sentenced to be imprisoned for a period of twelve years, his property was seized, and an appeal was made to the House of Lords; but the prosecution answered its intended end; the prestige

and magic influence of the poet ‘Liberator,’ as he was called, was destroyed; he himself henceforth spoke in more measured language, and the funds of the Repeal Association were nearly exhausted in the contest.

The return of the Whigs to power in 1846, and the ad-herence which Mr. O’Connell gave to their party, introduced a new era in the career of the great leader and his friends and supporters, over whom for forty years he had exercised an all-powerful influence. His health began to fail, and he became sorely by opposition, as well as depressed in spirits, at the early appearance of famine in Ireland. Early in 1847 he went abroad with the intention of spending some months in Italy, and of paying a devotional visit to Rome. He had not however proceeded further on his way than Genoa, when he suddenly sunk and expired on the 10th of May. He was the author of a hundred and thirty-five political pieces, compliance with his last wishes; and his body was conveyed to Ireland for interment. Besides three daughters, Mr. O’Connell left four sons, all of whom at one time or other have had seats in Parliament. His eldest son Maurice, many years M.P. for Tralee, died in 1853; and his second son, John, after representing several Irish constituencies, was appointed in 1856 to the Clerkship of the Hanaper Office in Dublin.

Life and Times of Daniel O’Connell, by his son, John O’Connell}

ODIHAM. [HISLAUR.] ODIHE, ADAM.
of its tone, and raised his name very high in the list of the living Danish poets, if it did not place him at their head. He used often to say afterwards that in writing ‘Aladin’ he had discovered his own ‘wonderful lamp,’ the vein of poetry which was to give him fame and fortune. He received in 1806 for this poem a travel stipend from the Danish government, and walked into Copenhagen, where he was at the charge of his board. Young Adam soon began to write not only verses but even plays, which were acted by himself, his sister, and some play-fellows, on Sundays, in one of the rooms of the Royal Danish Academy, which was a sort of rehearsal school to which the boy had been admitted, laughed at his attempts; and Dichmann, another Norwegian, who was one of the masters, told him, to his great mortification, that he was no genius—he would never become another Edward Storm, the latter having received the same academy fellowship to qualify him for a mercantile life; but when he left the school at the age of sixteen, he was glad of an accident which prevented his being placed in a conning-house, and readily persuaded his indolent father, who was in much better circumstances than he had been, to allow him to study. In a year however he was tired of Greek and Latin, and having for some months spent all his spare time and money at the theatre, was seized with a desire to appear on the stage. These ideas naturally fitted him in a self-conscious light in a foreign city than in an English one, and at Copenhagen the management of the drama was treated with unusual solemnity. In Rahbek’s Lectures on the Drama, dedicated to the stage, the stage is regarded as a mechanism, the engine hardly secondary in importance, at least. With the exception of the comedies of Holberg, the Danish Molière [Haukao], the plays that were performed were then chiefly translations. Of English pieces, says Oehlenschläger, ‘Mr. Scudéry’s and Mrs. Glavon’s’; of which Rosing was an excellent Sir Joseph [Joseph Surfaec], and ‘She Stoops to Conquer,’ in which Gielstrup was an in-comparable Tony Lumpkin.” He soon found however that he was not likely to rise to a much higher position than that of a walking gentleman, and the acquaintances of two young students, who had taken lodgings with the same landlord as himself, led him into a different line. They were the two brothers Oersted, afterwards so well known. Of the three, the younger, who always occupied for many months, in those obscure lodgings, one, Oehlenschläger, became the greatest poet of Denmark; another, Hans Oersted, became its greatest natural philosopher, and the discoverer of electro-magnetism; the third, Anders Oersted, who married Oehlenschläger’s sister, became its greatest lawyer, and for a time the prime-minister of the kingdom. Oehlenschläger infected the future lawyer with a love of poetry, and the lawyer infected him with a taste for jurisprudence. With the help of his lodgers he relinquished the stage, entered himself at the University of Copenhagen as a student of law, his friend promising his assistance to help him on a little more rapidly than usual. Literature however soon won the victory over law. The university offered in 1809 a prize for a moral or political sonnet. It is a good advantage for Northern literature if the Scandinavian mythology were made use of in it, instead of the Grecian! It was the very idea which was taking possession of Oehlenschläger, and was destined to occupy him for life; but when he drew up an essay he had the mortification to see the prize carried off by another —receiving himself however the honour of being declared the second best.

On the famous 2nd April 1801 when Nelson attacked the Danish fleet at Copenhagen, Oehlenschläger saw the fight at a short distance, from the balcony of the Sea-Cadets’ Academy, and afterwards held the post of ensign in a volunteer regiment of students. He also published a small dramatic piece, “The Second of April,” but it was of no great merit. “That battle,” he wrote, several years afterwards, “inspired the Danes with a taste for poetry, as the battles of Marathon and Salamis did the Greeks, and the destruction of the Spanish Armada the English in the time of Elizabeth.” It is not uncommon, indeed, that a war is required to drive the mean, the petty, and parochial out of a nation’s mind, and bring it in tune for the great and beautiful. In 1803 he issued a volume of poems, containing among other works, the ode of ‘The Eve of Saint John,’ and at once took rank as a writer of some note. The very next year, the tale, of ‘Aladdin,’ which, followed, found its way into the famous story in the ‘Ambian Nights,’ captivated the public, in spite of some very obvious faults, by the general vivacity open only to each other when they did not wish the children to understand them.

Up to the age of twelve, young Adam had been very unfortunate in the article of schools; he was then taken notice of by Edward Storm, a Norwegian poet, who offered to his father a gratuitous admission to a public school in Copenhagen, if his father would accept the charge of his board. Young Adam soon began to write not only verses but even plays, which were acted by himself, his sister, and some play-fellows, on Sundays, in one of the rooms of the Royal Danish Academy, which was a sort of rehearsal school to which the boy had been admitted, laughed at his attempts; and Dichmann, another Norwegian, who was one of the masters, told him, to his great mortification, that he was no genius—he would never become another Edward Storm, the latter having received the same academy fellowship to qualify him for a mercantile life; but when he left the school at the age of sixteen, he was glad of an accident which prevented his being placed in a conning-house, and readily persuaded his indolent father, who was in much better circumstances than he had been, to allow him to study. In a year however he was tired of Greek and Latin, and having for some months spent all his spare time and money at the theatre, was seized with a desire to appear on the stage. These ideas naturally fitted him in a self-conscious light in a foreign city than in an English one, and at Copenhagen the management of the drama was treated with unusual solemnity. In Rahbek’s Lectures on the Drama, dedicated to the stage, the stage is regarded as a mechanism, the engine hardly secondary in importance, at least. With the exception of the comedies of Holberg, the Danish Molière [Haukao], the plays that were performed were then chiefly translations. Of English pieces, says Oehlenschläger, ‘Mr. Scudéry’s and Mrs. Glavon’s’; of which Rosing was an excellent Sir Joseph [Joseph Surfaec], and ‘She Stoops to Conquer,’ in which Gielstrup was an in-comparable Tony Lumpkin.” He soon found however that he was not likely to rise to a much higher position than that of a walking gentleman, and the acquaintances of two young students, who had taken lodgings with the same landlord as himself, led him into a different line. They were the two brothers Oersted, afterwards so well known. Of the three, the younger, who always occupied for many months, in those obscure lodgings, one, Oehlenschläger, became the greatest poet of Denmark; another, Hans Oersted, became its greatest natural philosopher, and the discoverer of electro-magnetism; the third, Anders Oersted, who married Oehlenschläger’s sister, became its greatest lawyer, and for a time the prime-minister of the kingdom. Oehlenschläger infected the future lawyer with a love of poetry, and the lawyer infected him with a taste for jurisprudence. With the help of his lodgers he relinquished the stage, entered himself at the University of Copenhagen as a student of law, his friend promising his assistance to help him on a little more rapidly than usual. Literature however soon won the victory over law. The university offered in 1809 a prize for a moral or political sonnet. It is a good advantage for Northern literature if the Scandinavian mythology were made use of in it, instead of the Grecian! It was the very idea which was taking possession of Oehlenschläger, and was destined to occupy him for life; but when he drew up an essay he had the mortification to see the prize carried off by another —receiving himself however the honour of being declared the second best.
some time in Italy, beginning to feel home sickness, returned to
Denmark after an absence of nearly five years, and read
this production in manuscript to many of the most select
circles, which was followed by his ability in print at the University
in Denmark, in presence of the leading members of the court,
in the queen's apartments. The play, when produced in
Germany, became one of the most popular on the stage, and
had frequently acted for thirty years; and it also became a
favourite in Denmark. A translation of it into English, by
Theodore Martin, published in 1854, has, we believe,
with a general welcome, and all English critics regard
'the Erindringer,' as one of Oehlenschlager's principal titles to
fame.

Oehlenschlager had left Denmark in 1805, an eminent
rising poet. His reputation had risen higher and higher
during every year of his absence, and on his return in 1810 he
was welcomed as a hero. He had at the age of fifteen
engaged the hand of Christiana Heger, the sister of Camma
Rahbek, the wife of Rahbek the theatrical writer, whose
house on the hill (Bakkehus), a short distance outside the
city walls, had been since 1804, and continued till 1830, the
resort of the choicest literary society of Copenhagen. Rahbek
himself had in a fit of vexation just thrown up the post of
professor of esthetics at the university, and Oehlenschlager
obtained it, with the privilege of the king of being absent it
from the university. He has said, however, that he did not neglect to make use of.

Be this as it may, he celebrated his wedding in an unusual
way, but precisely in the style that Rogers, the English poet,
had promised to say would have been, if he had ever
ceded to be a bachelor. 'On the 17th of May, 1810,' says
the Dane's 'Erindringer,' 'I dined with Christiana at her
father's at Copenhagen, afterwards she and I drove our
together to Giffottie, where Pastor Hög, after I had shown
him the necessary papers, went with us to the church and
married us. We got into the vehicle again, man and wife,
and drove off to the beautiful Christianaholm, to Söllya,
which Count Schimmelmann had the kindness to offer us
for the night.' The account of his wedding and of the
notion that his husband had lost much by his dealings with
the booksellers, and under her advice he began to issue his
new plays and poems at his own risk, but soon convinced
himself that he understood nothing of the publishing busi-
ness, and his wife no more; a conviction which he says,
however, that his wife could never be persuaded to share.

During the next five years he wrote a number of plays of
various merit, but none that were equal to those he had
composed at home. He became a member of the literary
feud. Bægge, already mentioned as formerly the head of
the Danish Parnassus, had left Denmark a little before
Oehlenschlager, with the deliberate intention, although
in receipt of a pension from the government, of
never returning to the country, and of never crossing the
line of Danish. He now changed his mind, came back, and,
unable to see with patience the throne of poetry occupied by
another, though one whom he had himself applauded, com-
manded a series of critical onslaughts on Oehlenschlager, in
which the animosities was painfully apparent. The
public became disgusted, Bægge found himself in general
disavour, again expatriated himself, and finally died abroad.
It must however be owned, that Oehlenschlager stood in
need of a little criticism not too intolerant, and that he wrote
better after these attacks than he did at the time they com-
mented. In 1816 he made a second foreign tour to Ger-
many and to France, still using his pen when he halted, but
also driving home by every advantage after a twentyears
A long series of plays and poems followed, among which,
the most conspicuous was 'Nordens Guder,' the 'Gods of the North' (published in 1819), an attempt to combine into one
convenient whole all the scattered legends of the Edda.
This attempt has been pronounced insufficient to fill the
translation of the work into English verse of considerable merit by
W. E. Frye was published at Paris in 1845, and the poet
supplies much of the material for Pigo's 'Manual of North-
ern Mythology.' 'Deutsche Geschichten,' published in 1823,
were written in German, was, on the contrary, of a
unmistakably inferior character. Oehlenschlager, who at the
age of seven-and-thirty took lessons in English from Andersen
Felddborg, a Dane long settled in Edinburgh, and well known
to Willy Scott, entered into correspondence with Sir Walter
Scott to express his warm admiration of his novels; and, on being
encouraged, sent the manuscript of his own novel to England
to be translated by Mr. Gillies, but in spite of the zealous
exortions of Sir Walter, the affair fell through from his
inability to find a publisher. The author disclaimed the
work, and translated it himself. The failure was a
fortunate one for the fame of Oehlenschlager, which would
have suffered much in England from a work so unworthy of
him.

In 1829, when at the age of fifty, he lost his father. "He
was vain of his son," says the poet in the 'Erindringer'
"but, like a sensible father, he never allowed me to see it;
only sometimes I detected the feeling when he had been
indulgent, and reflecting my past conduct, he would talk
with strangers, and particularly with students on the bench
at the hill at Frederiksborg, and lead the conversation
to bear on me; when, if they said anything in my praise, it
shocked them, as he used to think he could not judge incorrulg.
Many good-natured people were of this, and often
afforded this innocent pleasure to the old man.

The death of his father, and the death of Camma Rahbek
and her husband about the same time, threw a gloom over
Oehlenschlager's spirits, and they were soon afterwards
relieved by a singularly pleasant incident. He took for
the first time in his life, in 1829, a trip across the Sound to
the coast of Scania, thinking, as the steamer approached
the Swedish shore, the strangest it was that, though it had always
treated his sign over the other terraces of the hill at Frederiksborg, he had lived half a century, and been to
Rome, without ever passing the straits. A brilliant reception
awaited him from all ranks in Sweden: addresses were pre-
pared for him: the University of Lund sent him a
bachelor. The ceremony of the inauguration of a
rector of the university at the cathedral of Lund in company
with Tegner, the Bishop of Wejxio, who was acknowledged
by all as the first poet of Sweden, and was by many con-
dered to have surpassed in his 'Frithiof' any single work of
Oehlenschlager's. Tegner, in the course of the delivery of a
poetical address in hemistichs, suddenly pronounced the
lines-

'Skilskerna Adam är här, den Norderländske segervolken,
Thernfragen I Diktningens veiri by Thorens & Goebels;'

(The Adam of poets is here, the northern monarch of minstrels,
Host of the poems is here as the poet of the people.)

and in the presence of the crowd that filled the
cathedral, among whom were Oehlenschlager's wife and children,
he was acclaimed a laurel crown on his head, amidst a burst of music and
the roar of cannon. The event, from all its circumstances,
assumed almost a national significance. Tegner and some
other eminent literary men were made honorary citizens of
Copenhagen. A few days after the King of Sweden sent the Order of the
North Star to Oehlenschlager.

Honours continued to shower on him after this; one of
them, the gift of free lodging by the king, seems however to
have been regretted, as he did not like to live in a
house. His own dwelling in Christian VII,' he tells us,"granted me permission to live
for one summer in the house of the castle steward at FREDERIKSBORG, (the house which had been the official residence
of his father). I wished very much to get the permission
extended to more summers than one. When I asked
the king for his kindness, he asked me if there was not a garden
belonging to the house, and if I was not fond of gardening.
This gave me an excellent opportunity of bringing in
my petition. I answered that I should like very much to
garden, and if I could hope to gather some of the fruit afterwards.
The king said that if it was practicable I should have permission
to live there; and I then told him, in the lively tone in
which I like to hear him speak, 'For your Majesty a good
deal is practicable.' He then gave me permission to
keep the house.' Soon after, the poet tells us, he changed it
for a better.

In 1844, on another visit to Paris, Oehlenschlager
was repeatedly invited to court by Louis-Philippe, who
one day, on one occasion to a gentleman, whom he afterwards found
ought to be King Leopold, who told him he had read all his
works in German, and invited him to Brussels. A visit which
he paid to Norway, and another in 1847 to Sweden, were like
the triumphs of the last days of his sixty-seven birth day his play of 'Amleth,' on the same
story as Shakspere's 'Hamlet,' was produced at Copenhagen.
It was completely successful, and the King of Denmark
wrote him a letter to congratulate him on his triumph.
On his seventieth birthday, the 14th of November, 1849, a grand

3 P
festival was given in his honour in the great saloon of the Royal Shooting-Gallery. All the leading poets of Denmark were present, and many of them wrote a song for the occasion. Within a week of the funeral of Oehlenschlager the thanks, in which he alluded to his being near the termination of his career, but said—

'Quod a nobis amicitia
Spinoza,'

and into Orphan, which Shakspere's like closed well, felicity, drama, Walter whom masters a of the representatives were the boy great Flamand's of the of the Great'); Foersan of the of the Scandalous, or

In little more than two months he was destined to be borne along the avenue to which he had thus symbolically alluded. An illness which did not at first seem serious soon became; and about eight o'clock in the evening on Sunday the 20th of January 1850 he felt the approach of death. At half past nine he called to his eldest son and told him, 'At the moment I am going to die I wish them to exalt my own tragedy of 'Socrates.' Read to me now that part of the scene in the fifth act between Socrates and Cebes, in which Socrates speaks of death, is so unapathetically beautiful.'

The son read the passage—

'How then can Death afflict thee?
It can do nothing thee, Cebes,
It must be something or it must be nothing.'

ending with

'Think what a joy then that must be
When the gods themselves to live,—to speak
To Shakspere, with Orpheus and with Homer.
And all the great men who have been before us.'

He heard this passage read with the greatest emotion, looking round him with a smile of pleasure. When it was concluded he put an end to the reading and took leave of his family who were standing around the bed. As the clock struck eleven he expired.

The funeral of Oehlenschlager was a national solemnity, like that of Thorvaldsen a few years before. The funeral procession consisted of about 3000 persons, including repre- sentatives of the queen, the grand hierarchies of the land, the foreign ambassadors, the professors of the university, the clergy of the capital, and all that was most distin-
guished. As it emerged from the western gate of Copenhagen it passed the house in which the deceased was born, and halted while the musical societies executed a solemn 'Prela-
well,' composed for music by Andersen. The procession closed at the church of Frederikskirke, where lies the poet. Grundtvig and Bishop Mynster spoke over the poet's grave. It is the custom in Denmark, his father was organist, and where the body first attended divine service.

The estimation in which Oehlenschlager is held by his countrymen is best shown by the commencement of him in Flamm's 'Galleri af berømmte Danke Mænd og Kvinder.' It is divided into seven parts. The first part is devoted to the great powers in the world of art and poetry, since it has a sculptor to show like Thorvaldsen, whom only the great masters of antiquity can be considered to rival, and a poet like Oehlenschlager, who can worthy take the fourth seat by the side of the three heroes of poetry, Shakspere, Byron, and Götche.

Forsem the translator of Shakspere into Danish sent a copy to Oehlenschlager inscribed 'To William Shakspere's Twin-brother.' The English writer however to whom Oehlenschlager bears by far the most resemblance is Walter Scott. Though the great Shakspere was unfortunate in pure fiction and the great Scottish writer in the drama, the series of the Scotch novels of the one may be most aptly paralleled by the series of Danish tragedies of the other. In both there is an excellence of life, a rare felicity, an apparent ease of production, a wonderful breadth of effect.

Oehlenschlager's tragedies are twenty-four in number, and nineteen are on Scandiavian subjects. They are arranged in the last edition in chronological order, and touch upon almost everything of any great interest or importance in Scandinavian history or tradition. Besides those that have been already mentioned there are—'Krud den Store' ('Our King'), 'The Three Famous Men of Gustavus Adolphus' ('The Varinger in Constantinople'), the hero of which is one of the northern body-guard of the Hungarian monarch, who were taken as a subject after Oehlenschlager by Sir Walter Scott. 'The Wise Man of Mecklenburg,' 'In the Land of the Lost,' 'Landsknecht og Forstvæv,' ('Land Found and Lost'), in which are dramatised the incidents of the early discovery of America by the North-
time the identity of the forces of magnetism and electricity had only been suspected. He now demonstrated that "there is always a magnetic circulation round the electric conductor, and that the electric current, in accordance with a certain law, always exerts a determined and similar impression on the direction of the magnetic needle, even when it does not pass through the needle, but near it." For this discovery he received the Copley medal of the Royal Society of London, and the French Institute presented him with one of its mathematical class prises worth 3000 francs. In 1809 he wrote a "Manual of Mechanical Physics," a second edition of which was published in 1844. The rewriting this work led him to make many original researches in the field of physics, many of which have not been enriched by his experiments. He made many important experiments on the compression of water, and invented an instrument by which liquids might be compressed with more certainty. He was the first to demonstrate the existence of the metallic aluminum in alumina, and made other chemical discoveries. In 1828-29 he again visited Germany and France, and also visited England. On his return to Denmark he founded the Society for the Distribution of the Works of the Learned, through which he set up a body of popular lecturers to deliver courses of instruction in the most important towns of the country. He took an active part in the Scandinavian Society of Naturalists, which, like the Asgrowdian Mathematical Society, assembled annually in different parts of the country. He again visited England in 1846, during the meeting of the British Association at Southampton.

As he increased in years honours increased upon him. He was elected a corresponding member of the Academy of Sciences in the French Institute; and Director of the Polytechnic School at Copenhagen, which he had himself founded. In 1857 he was made Knight of the Legion of Honour; and in 1849 Knight of the Frisian Order of the Golden Fleece. In 1855, the Reward of Merit in the Arts and Sciences. In early life Oersted was associated with the poet Oehlenschläger, whose sister was married to his younger brother, and although devoted to experimental science, he yet took a deep interest in the proposition and development of Danish literature. He was a constant writer for the newspapers and magazines. Acting upon the deep conviction that science should be the handmaid of religion, he did all that lay in his power to make the popular mind of his country acquainted with the facts of natural science. He wrote a lyrical and didactic poem called "The Balloon," which was translated into German. He was also one of the most popular lecturers of his day. He not only lectured in the university to young students, but also delivered courses of lectures on the subjects of public and national interest. A variety of Oersted's papers and lectures of a popular kind have been translated into the English language by the Misses Horner, under the title of "The Soul in Nature, with Supplementary Chapters on Christian Ethics." On the 9th of November 1850 a jubilee was held in honour of the fiftieth anniversary of his services at the University of Copenhagen. On this occasion people of all ranks and opinions assembled round the noble old philosopher. The king of Denmark presented him on the occasion with a country residence at Frederiksborg, near Copenhagen. He lectured through the winter, but the following March he took a severe cold, which terminated in inflammation of the lungs, and on the 27th March 1851 he died. An extraordinary national sketch of Oersted, to which we are indebted for some of the materials of this notice, was published by P. L. Möller, a translation of which is published with the English translation mentioned above.

OERSTEDT. [MINSTERVÆR, S.]

GESTRUS. [Bovs, [Gestrak.]

OFFENCES AND PUNISHMENTS. The punishments under the criminal law had been greatly mitigated previous to 1846. In consequence of this, and perhaps still more, the number of convictions and commitments increased. The metropolis by Sir R. Peel's Act, the 10 Geo. 4, cap. 44, which has been gradually extended to the whole of Great Britain and Ireland, though the number of executions has decreased, has greatly increased the certainty and the definiteness of convictions. In 1831 the number of commitments had been 19,647, of whom 3047 were females. Of these, 13,830 were convicted, and 1,801 sentenced to capital punishments. Of these only 23 were executed, 12 being for murder. Up to 1834 there had been no classification of offences. From that year and subsequently they have been classed under the following heads, from which it will be seen that the increase of offences has been, in England and Scotland, chiefly in offences against property without violence; Class 1, offences against the person; Class 2, offences against property, committed with violence; 3, offences against property, committed without violence; 4, malicious offences against property; 5, forgery and offences against the currency; 6, forgeries against the Revenue; 7, forgeries against the public revenue; 8, forgeries against the post office; 9, forgeries against the Bank of England; 10, forgeries against the Bank of Ireland; 11, forgeries against the established church; 12, forgeries against the librarians. The following is the account of the different classes of offences:

In 1834 there were 20,731 commitments of which 2016 was under class 1, 13,354 under class 2, 15,478 under class 3, 158 under class 4, 308 under class 5, and 1359 under class 6. Of the total 14,729 were convicted, of whom 923 were sentenced to death. Of the total 13,243 were convicted, of whom 21 were for murder. In 1840 there were 27,187 commitments, of which 21,484 were under class 3, and 19,987 convictions; of these 77 were sentenced to capital punishments, 8 of whom were executed, all for murder. In 1845 there were 24,303 commitments, of which 19,006 were under class 3, and 17,409 convictions; of these 49 were sentenced to capital punishments, and 12 executed, all for murder. In 1850, in England there were 26,815 commitments, of which 16,849 were under class 3, 21,353 under class 3, 238 under class 4, 650 under class 5, and 744 under class 6. Of the total there were 20,539 convicted, of whom 49 were sentenced to capital punishment, and 9 executed. There were 31,326 commitments, of which 4903 were under class 3, 2828 under class 4, 763 under class 5, 463 under class 6, 250 under class 5, and 7431 under class 6. Of the total only 17,106 were convicted, of whom 17 were sentenced to capital punishment, and 8 executed. In England and Ireland in 1856, there were 21,437 persons committed for trial, of whom 15,425 were males and 4012 females; of these, 4873 were acquitted or discharged and 31 were found insane; of the number convicted, 1394 were for offences against the persons 1757 for offences against property with violence, 10,468 for offences against property without violence, 94 for malicious offences against property, 767 for forgery and offences against the currency, and 345 for offences not included in the preceding classes and including misdemeanours; 69 were sentenced to death, of whom 16 were executed; 57 were transported for life, and 216 for terms exceeding ten years; 2158 were sentenced to penal imprisonment for terms varying from four years to life, 1,154 were committed to various imprisonment establishments from one month and under to one year, and in this class, in the terms between six months and one month or less, the numbers show a remarkable decrease from previous years; in 1856 the numbers were 7800, against 1854 8400; and 1849 19,647, and the same year was the first in which the lowest was the smallest amount in any year from 1847; 222 were ordered to be detained in reformatory schools, and 127 were whipped, fined, or discharged on sureties. The great decrease in the number of commitments is probably to be attributed in a considerable degree to the extended provisions of the Summary Convictions Acts. On summary proceedings, the number of cases under the Criminal Justice Act, was 11,272, and under the Juvenile Offenders' Act, 2631. Altogether there were 22,428, and 13,923 convicts, of whom 11,408 were for debtors on civil process, and 7537 under the Mutiny Act. The total shows an increase of convictions in 1854 over 1853, and there is a decrease of 7000 in the number of summary convictions. Of the commitments, omitting debtors and military prisoners, which reduce the number to 21,019, there were 1372 in commitments under 21 years of age; 11,901 of persons between 12 and 16; 24,688 for的各种 between 16 and 21; 33,400 between 21 and 30; 20,973 between 30 and 40; 11,343 between 40 and 50; 5519 between 50 and 60; 2732 above 60; and 920 of whom the age was not known. The average number of persons committed, of whom 61,253 could read or write and write imperfectly, 6108 could read and write well, 318 had received superior instruction, and of 8371 the instruction was not ascertained. The county and borough prisons are stated to be constructed to
contain 26,447 prisoners; the daily average of prisoners is 17,764, and the greatest number at one time was 24,055: but, though the number may be room enough, some prisoners are terribly overcrowded.

In Ireland in 1856 the total number of persons committed or held to bail for trial was 7009, of whom 3075 were either acquitted or discharged. Of the number committed, 173 were sent to prison for forgery and against the currency, 556 for offences against property with violence, 2854 for offences against property without violence, 78 for malicious offences against property, 75 for forgery and offences against the currency, and 1143 for other minor offences. Of those committed, 65 were sentenced to death, and 3 only executed; 14 sentenced to transportation for life, and 372 to other periods of transportation or penal servitude; 2798 to various terms of imprisonment; and 982 were whipped or fined, or discharged on parole. Of those not convicted, 55 were outlawed, 7 were found insane, 55 were found guilty, and 179 not proven; the remainder were discharged without trial.

Of the genera of Plants belonging to the order of Fungi, some of the species of which are found upon the human body and others attack plants. It is known by possessing a simple or branched mycelium, which is very minute and pellicular, aggregated into floculent masses softly interwoven and not divided. In the genus Oidea, the mycelium is simple and pellicular, and arises from the joint of the mycelium. O. albicans, the Thrush-Fungus, is found in the mucous membrane of the mouth, fauces, and orophagus of sucking children, and also occasionally in grown-up persons in a state of extreme exhaustion. The nectarium, amidst the discharge of which this fungus is found, are usually called thrush. Although constantly present in this disease the fungus does not appear to produce the disease, but to be the result of an excited condition in the patient. It has been observed that the mucous membrane in this state constantly affords an acid reaction, and this acidity seems necessary to the growth of the fungus. The best account of the disease was founded in the work 'Déploration des Végétaux Parasites.' Several other species of Oidium have been described. The fungus found in connection with the recent grape-vine disease is an Oidium. [Entophyta, &c.]

OIL-PALM. [ELMA.]

OIL-TREE. [BAMBA.]

OILS. The Fixed Oils are mostly products of animal organization, in the fat and adipose tissue; but are found also in plants, generally in the seeds, but in some cases in the fruit, as in the olive. They are composed of carbon, hydrogen, and oxygen, and are liquid or solid according to the manner in which these elements are disposed, most of them consisting of two compounds, a liquid called Olein, and a solid called Stearin, though another solid called Stearin. The Volatile Oils are mostly products of vegetable organization, and are so called on account of the ready manner in which they are volatilized by heat. Plants owe their peculiar odours to these volatile oils. They are divided by chemists into three groups; those which consist of only carbon and hydrogen, as oil of turpentine; those which contain also oxygen, as oil of cloves; and those which contain sulphur, as oil of garlic. [Ova.]

In 1805, a celebrated Swiss naturalist, was born on Offenberg the 2nd of August 1779. He studied medicine and natural history at Göttingen, and held the position of privat-docents in that university. In 1807 he became extraordinary professor of medicine in the university of Jena; then transferred to Göttingen, and was in 1819 professeur ordinaire de philosophie; in 1822, professor of natural history till his death. At the time he began to study natural science, the writings of Kant, Fichte, and Schelling were producing a deep impression on the minds of the students of natural history. Schelling, who had some familiarity with the principles of the transcendental philosophy to the facts of the natural world, and had by a process of thought endeavored to give an explanation to the phenomena of nature. It was in this school that Oken stated his views in the forms and the development of animals. In his classification he took for his basis the presence of the sense, which is the organ of observation of the animal to the environment in which it lives. In his work 'On Generation' he first suggested that all animals are built up of vessels or cells. In 1806 he published his 'Contributions to Comparative Anatomy and Physiology,' and pointed out the origin of the intestines in the nimbilial vessel. In this year he made an excursion to the Harz Mountains, which resulted in an important thought. This may be described in his own language: 'In August 1806,' he says, 'I made a journey over the Harz. I said to myself: Let us perceive in the animal kingdom a likeness to the way of man, and since that time the skull has been regarded as a vertebral column.' This discovery was published in an essay on the 'Signification of the Bones of the Skull.' This essay, although it attracted little attention at first, laid the foundation of those inquiries which, in the hands of Christoph Geyffroy St-Hilaire, and Owen, have led to the establishment of those laws of homology in the vertebrate skeleton that are now a universally received branch of anatomical science. It was by the persevering use of the idea that flashed across his mind, which he had acquired from these writers, that Oken laid the widest possible view of natural science, and classified the mineral, vegetable, and animal kingdoms according to his philosophical views. The transcendental philosophy has never been popular in England, and the transcendentalist views of Oken have been little read in England. The generality of writers on natural history in this country, so that this work has been frequently regarded as the offspring of a diseased imagination rather than the cool decisions of a philosopher. Nevertheless, the author was pleased at its translation, and wrote a preface to the English edition. However little value this work may be as an introduction to modern science, it is interesting as a document in the history of a great mental movement, and contains the germs of those principles which are now regarded as the secure generalisation of well-observed facts.

From the date of the publication of this work to the day of his death, Oken incessantly contributed to the literature of natural history. In the year 1817, he started a natural history journal called 'Annalen der Naturforschung,' which has been continued in this form for thirty years, and which contains a large series of his papers on every department of natural history. Though a transcendentalist in philosophy, he was an energetic and acute observer, and has contributed largely to the individual history of the animal kingdom.

He was greatly respected throughout Germany, and it was at his suggestion that the first meeting of natural philosophers took place in 1822. The German Association which thus was instituted lasted for thirty years, and has assembled in large towns of Germany, whilst every country in Europe has imitated this example with great and increasing success. Oken died full of years and honour, at Zurich, in August 1847. OKENF. [MINERALOGY, &c.]

OILS. The following table and account of the Old Red-Sandstone Formation is given by Professor Ansted in his 'Elementary Geology':—
by this formation; and its vast thickness is well displayed in the cliffs crossed by the new road from Leominster to Hereford. In the northern portion of the range, and near the mouth of the Towy Valley, the limestones are most fully developed, becoming much thicker and almost more crystalline than in other parts.

In Scotland the uppermost beds are highly arenaceous, and often consist of sandstone conglomerates. The intermediate calcareous beds are composed of fossils which have a more regular composition, yielding unequally to the weather, and exhibiting a brocaded aspect. It contains masses of chert exceedingly hard, and these, from the manner in which they are incorporated with the rock, appear to have been of contemporaneous formation. The lower beds consist of firm, calcareous sandstone, with a few grits and flints, and are very persistent, being found both in Moray and in Fifes, localities 120 miles apart.

The middle group of the Old Red-Sandstone of Scotland, corresponding to the Cornstone of England, is developed in Forfarshire, in Morayshire, and in the Grey-Sandstones of Berwickshire, where the lower beds are absent. It is represented as consisting, for the most part, of rocks of a bluish-gray colour, sometimes, as at Dalraddy, resembling the silurian sandstones, at others forming a hard fissile flagstone exported as a paving-stone, and occasionally appearing in beds of friable stratiifed clay, easily washed away by the sea. The colour however throughout is gray, and in this respect differs essentially from the English contemporaneous beds, which are chiefly reddish brown or marly.

The base of the whole system is represented by Mr. Miller as consisting of an extensive and thick conglomerate rising into a loamy mountain-chain in the county of Caithness, and consisting of 2000 feet of conglomerates, and from Huvord's bay, near the island of Lewis, there is a considerable thickness of conglomerates, and from these the Devonian System is derived.

The Devonian Beds appear to be composed of the whole series of the Old Red-Sandstone, the upper beds of which are so much compressed and modified, as to form the rocks of the Carboniferous Series.

The most striking peculiarity of the Devonian System is the great thickness of the rocks, which are composed of sandstone, limestone, and conglomerates, and in many places they reach a thickness of 5000 feet. The most striking peculiarity of the Devonian System is the great thickness of the rocks, which are composed of sandstone, limestone, and conglomerates, and in many places they reach a thickness of 5000 feet. The most striking peculiarity of the Devonian System is the great thickness of the rocks, which are composed of sandstone, limestone, and conglomerates, and in many places they reach a thickness of 5000 feet.

OLDBURG, Worcestershire, a town in the parish of Hales Owen, is situated near the junction of Staffordshire, Shropshire, and Worcestershire, in 52° 30' N. lat., 2° W. long., distant 49 miles N.N.E. from Worcester, and 180 miles N.N.W. from London. The population of the town of Oldbury is given in the Returns of the Census of 1851 as 5114, but this does not include the whole of the town. The entire population in 1851 was 11,691.

The town of Oldbury has had very much increased of late years, owing to the extension of the iron trade. The parochial chapel of Christchurch is a commodious brick edifice with a square tower. There are chapels for Wesleyans, Primitive, and New Connexion Methodists, Baptists, Independents, Christians, and Roman Catholics, and Unitarians; and National, Free, and other schools. Besides numerous iron and coal mines in the vicinity, there are manufactures of iron and steel, locomotive engines, malt-mills, edge-tools, hollow iron ware, bricks, earthen draining tubes, and of alkali. Boat-building is carried on, and there are corn-mills and breweries. Oldbury is nearly surrounded by the Birmingham Canal; the river Tame runs through the town, turning several mills in its course; and the Stour Valley Railway passes close to it. A customary market is held weekly on Saturday. A county court is held in the town.

OMMASPIRITES. A genus of Cuttle-Fishes belonging to the family Teuthida. Body fleshy, firm, cylindrical, elongated, flanked near its posterior extremity by two triangular fins. Locomotive apparatus formed of "conical per-

pendicular pita, each communicating by a narrow groove with a small horizontal pit, surrounded by a prominent margin, the whole of this being more or less raised on the surface of the body, and forming a rather prominent elevation at the base of the locomotive tube; and, besides, of a tubercle prolonged into its upper part into a decreasing nose-shaped crest; and lastly, of little horizontal inferior crests placed on the inner margin of the body." Eyes very large, opening widely exterioy, and provided with a lachrymal sinus; arms 10, like those of Loligo; pen conoress, flexible, elongated, as long as the body, terminating at its lower extremity in a hollow ample cup.

This Cuttle-Fish of this genus closely resembles those belonging to Loligo. Besides the character just given, they may generally be distinguished by the short rhomboidal termination of the body, formed by the fins, combined with the kindred similarity. These species are the most pelagic, and some of them are gregarious. They seem to be distributed all over the world. They are called Flying Squids by Fishermen. (Forbes and Hanley.)

The following species have been taken on the British coasts:

O. sagittata (Sepia Loligo, Linnaeus), with an elongated body; peduncles of tentacular arms without suckers; extremities of their clubs covered with closely set rows of numerous small teeth. This species is frequently found on the British coast, but Moors. Forbes and Hanley record two instances of its recent capture. M. d'Orbigny regards the Loligo Pleioneum, L. Harpago, L. illecebrosa, and L. Coincidenti as found in British seas.

O. todarum (Loligo sagittata, Lam.), Delle Chiaie. It has an elongated body, and the peduncles of the tentacula provided with suckers throughout their length. This squid is often called in British catalogues Loligo sagittata. It is frequently found on the coasts of Great Britain. It has been made the subject of an elaborate memoir on the anatomy of its nervous system by Mr. Albany Hancock.

O. olkana (Ball), has a short body; suckers confined to the club of the tentacles, minute, and 4-ranked at their extremities. It has been found in Dublin Bay, and was first described by Dr. R. Ball of Dublin. (Forbes and Hanley, History of British Mollusca.)

OPHAREA, a genus of Plants belonging to the natural order Euphorbiaceae. The seeds of one of the species are said to be eatable when the embryo is extracted, but if this is not done, they are too caustic for food. On the authority of Mr. W. McLeay, Dr. Lindley says this nut is most delicious and wholesome, and that it is known by the name of Opharee Nut in some parts of America. Other euphorbiaceous seeds have the same properties.

O. triandra is a Guiana plant with a white juice, which turns black on drying, and is then used as ink.

OL. [Geology; Oolite.]

OOLITE. [Geology; Oolite.] At one time it was supposed that the little round masses which are so characteristic of the Oolitic Formation were portions of limestone which had gathered round various forms of minute fossil animals. It was suggested that these organisms were probably Foraminifera. Recent microscopic investigations have however shown that these little round bodies are purely inorganic, and that they are formed in the same manner as the larger nodules of the magnesian limestone.

The oolitic deposits are divided naturally in England into three parts, the Upper Oolite resting on the Kimmeridge Clay, the Middle Oolite representing the Oxford Clay covered by the Coral Rag, while the Lower Oolite is more variously composed of numerous bands of clay, sand, and limestone.

The Upper Oolites, called on the Continent the Portlandian Group, are, so far as the British Islands are concerned, almost entirely confined in their development to the south of England, only that stratum of clay which usually forms the base of the group being exhibited in Yorkshire, in the vale of Pickering.

The group of strata containing the Portland stone, and exhibiting the Portland Island, includes several layers of coarse earthy limestone, which rest on a bed of siliceous sand, mixed with green particles. This is called the Portland Sand, and sometimes attains a thickness of as much as 60 feet in the west of the island, and forms a complete passage into the underlions.

Above the coarse limestones of the lower part, which usually consist of alternate hard and soft layers to a thickness of...
of 50 or 60 feet, there are three beds of serviceable stone, interstratified with clayey or silicious bands. Fossils occur in all these strata; but they are rare in those beds of the stone which are worked to advantage for economical purposes.

In the upper part of the Portland series there occurs a very interesting bed, about a foot in thickness, of a dark-brown sub stance, containing much earthly lignite. This bed, called the Dirt-Bed, seems to be made up of decaying roots, which at some remote period may have been the surface of a ree. A portion of whose stems are now fossilised around it. Wherever the dirt-bed is laid open to extract the subjacent building-stone these remains of trees occur, and they are placed at such distances from one another as trees growing in a modern forest.

It results from the circumstances of this deposit, that the surface of the Portland stone, at the termination of the Oolitic period, must have been for some time dry land, and covered with a forest; and we have a kind of measure even of the duration of this period in the thickness of the dirt-bed, which has accumulated more than a foot of black earth, loaded with the wreck of its former vegetation. "The regular and uniform preservation also of this thin bed, described above, shows that the Ranges from dry land to the state of a fresh-water lake or estuary (which the nature of the overlying rock proves to have success ed the period of dry land) was not accompanied by any violent denudation or rush of water, since in the loose earth, together with the trees which lay prostrate on its surface, must inevitably have been swept away had any such violent cata strophe then taken place."

The Kimmeridge Clay is of a blue, slaty, or greyish-yellow colour, which is a consequence of the quantity of siliceous or crystallised salt of lime. Its usual effervescence with acids, and exhibits in tolerable abundance both vegetable and animal impressions, although its fossils are of a general kind, and less numerous than in the collection. It is a bed of great thickness; horizontal, or nearly so, in its stratification; extremely persistent in its peculiar mineral and fossil characters, but not very extensively developed either in England or on the Continent. The name Kimmeridge Clay, has been applied to its because it is well exhibited at Kimmeridge Bay, and near the village bearing the same name in the Isle of Purbeck.

At this spot there are also found, alternating with the clay, certain beds of highly bituminous shale, occasionally used for fuel, and locally known as the Kimmeridge Coal. There are many beds of lignite found in the Oolites, but these are perhaps the most remarkable, next to those of the lowest Oolitic deposits of Yorkshire and North Antrim.

Among the foreign rocks of this part of the oolitic period are—1st, the Calcaire de Blangy, on the coast of Normandy; 2nd, the upper beds of the Jura, in Switzerland; and 3rd, the Solenhofen beds. The three ranges of the Donets, in Southern Russia, there are beds of Oolitic Limestone of light-yellow colour, which appear to belong to this division of the secondary series. The Middle Oolites consist for the most part of a thick bed of clay, called the Oxford Clay, widely expanded throughout England, and not unlike in the same form on the Continent, and a series of overlying limestones, chiefly remarkable for the abundant remains of coral found in them.

The upper beds of the middle Oolitic Series are partly calcareous and partly sandy, the former consisting chiefly of a very interesting group of corals known under the name of Coral-Rag, and the latter, the sandy beds, or calcarious grits, often more or less intermixed with calcareous matter, and containing thin laminae of clay sometimes passing into irregular Fossils of hard and tough marly rock. This calcarious matter seems entirely due to the presence of crushed and decomposed organic remains.

The Oolitic system embraces also the formation called Lias. In England it consists of a series of strata in which an argillaceous character predominates throughout; it also contains limestone mixed with clay. It seems to form four principal members, which are thus described by Professor Ansted.

"The Upper Lias, or Alum-Shale, is best seen at Whitley, and on the low ground near the Walls of Lincoln, where it is more remarkable in the different parts of England where it is most developed. The dark blackish-grey, united with the singular ribbed-like structure, is more particularly remarkable in the upper beds of the formation, and is well seen by a fine-grained ferrigenous sandstone, slightly oolitic in structure, and containing a few fossils, marking the close of the Middle Oolitic period.

In the north of England the contemporaneous bed is a coarse sandstone, containing corals, but (as at Alum, in Yorkshire), including a considerable portion of fossil remains of shells, both bivalves and invertebrals. The bed never loses its coralline character, and may perhaps represent an imperfect coral reef, once extending from the north-west of England to what is now the right bank of the Humber.

The Oxford Clay is a very important member of the oolitic series, attaining a thickness of not less than 500 feet, and spreading over a great part of England—more especially occupying the fen-districts in the counties of Lincoln, and North-este, which appear to be partly caused by the action of this bed with the Kimmeridge Clay, producing a wide expanse of flat and undrained country. The same deposits are well seen at Weymouth; and they cover an important part of the East Riding of Yorkshire. The stratification throughout is nearly horizontal and undisturbed, being conformable with that of the formations immediately above and below it.

The appearance of the Oxford Clay is that of a stiff pale-brown argillaceous bed, containing a large proportion of calcareous matter, and a more or less abundant mixture of iron pyrites. Numerous organic remains are found in it, which are sometimes developed in the clay itself, but more frequently form a calcareous nodule, about which iron pyrites have aggregated. Those preserved in the clay have been generally found in a very rotten condition.

The Lower Oolites afford considerable ambiguity in the British Islands, but the details seem to be rather local than general interest; and though partially extending to Normandy, are by no means universal in other parts of Europe.

1. The Cornbrash (the uppermost bed) consists of a variable thickness of clays and sandstones, which ultimately pass into a thin rubbly stone, tough and occasionally crystalline.
2. The Forest Marble, which consists of carbonate of lime.
3. The Great Oolite, consisting of a variable series of coarse shelly limestones.
4. The Bradford Clay, consisting of a pale-greenish clay, containing a small proportion of calcareous matter, and including thin slabs of tough brownish limestones.
5. The Great Oolite is separated from the next bed, containing amongst them the clay used in the manu facture of cloth under the name of Fullers' Earth, and also a thin calcarious fragment, known as the Horsefield Slate. The latter is remarkable for containing the remains of Marsupial Animals. [MARSUPIALIA.]
6. The Inferior Oolite is the last of the series of oolitic limestones. It is employed to a great extent as a building material. Its representative in France is the Caen-Limestone.

The oolitic system embraces also the formation called Lias. In England it consists of a series of strata in which an argillaceous character predominates throughout; it also contains limestone mixed with clay. It seems to form four principal members, which are thus described by Professor Ansted.

"The Upper Lias, or Alum-Shale, is best seen at Whitley, and on the low ground near the Walls of Lincoln, where it is more remarkable in the different parts of England where it is most developed. The dark blackish-grey, united with the singular ribbed-like structure, is more particularly remarkable in the upper beds of the formation, and is well seen
at Lyme Regis, Whitley, and Barrow-upon-Soar, in Leicester-shire."

"The principal locality of the middle beds of the Lias is the neighbourhood of Chelltenham, where the marine line of Dumbleton Hill is crowded with interesting organic remains. It is made up of alternating layers of coloured clays and sands, which are occasionally calcareous, and of beds of impure limestone."

"This part of the series is also represented in the north of England, where it has an average thickness of about 130 feet, and consists of sandy shales, of which the upper portions are distinguished by the presence of several bands of agglutinaceous iron nodules.

"Lower Lias Shale.—The great mass of the lower division of the Lias is found in the middle of England, and consists of thick beds of dark-coloured and finely laminated shale, in which are interbedded beds of sandstone and limestone. These form the base of the series, and graduate downwards into a whitish sandstone, belonging to the uppermost beds of the New Red-Sandstone system. The transition is different again in the south of England; and at Lyme Regis marks of a light-blue colour represent the upper beds of the New Red-Sandstone and pass into the Lias Limestone by a succession of dark slaty marls, which are overlaid by a number of gray calcareous beds, these again by other slaty marls of the upper series. The same beds of the Lower Lias Shale are not present in this part of the deposit in their ordinary form.

"The lowest portion of the Liasic System occasionally consists of a very thin bed, in some places entirely made up of fragments of fossil bodies (chiefly the remains of fish), but sometimes it passes into a white micaceous sandstone, still recognisable as the same bed. This bed was first observed under a small patch of Lias, near the town of Ayst (situated on the left bank of the Severn, nearly opposite the mouth of the Wye); but it has since been recognised at Axmouth, in Devonshire, and in other parts of England farther north, having a total range of upwards of 100 miles. It is barely more than 3 or 3 inches in thickness, but invariably occupies the same geological position, and is for the most part as high as a man's head, and remains, that a long period must have been required for its formation. In some parts of the country, and especially in Gloucestershire and Worcestershire, the passage of the Lias into the underlyin beds of New Red-Sandstone is marked by the presence of calcareous flagstones, called Lower Lias Limestones; and these usually alternate with laminated shales, the whole in that case forming together the lowest deposits of Lias.

"On the Continent the Lias is frequently found, and the appendages of plants and animals developed in those middle beds, if not all the calcareous, however are usually more calcareous, and the lower more sandy, and these latter sometimes, as in Belgium, pass insensibly into the upper New Red-Sandstone. The town of Luxemburg is built on a hard sandstone of this kind, and these beds pass into the rock called Arcy, a peculiar and often metallic ferriferous metamorphosed deposit, occurring where the Lias sandstone in contact with crystalline rocks. Fossil have been found in South America, and also in Northern India, attributed to the period we are now considering.

"The Lias is a formation exceedingly rich in fossils; and amongst them are representatives of all the principal natural groups. Corals however are exceedingly rare, and of small size. Encrustations are numerous and abundant, especially the Pentacrinites, which attached itself to floating wood. Radiated animals of other kinds characterise parts of the deposits, and of these the Diadema is an example. Insects and Crustacea have been frequently found. Star-Fishes are common in the latter part of the series.

"Both oval and bivalve shells of various kinds are characteristic either of the whole deposit or of different beds. The Spire is one of the latter species of a genus represented far more abundantly in ancient deposits, while the Pecten and Cardium are among the most abundant representatives of more recent forms. The Pecten is an example of a similar kind; and the Ammonite and Belemnite are eminently characteristic cephalopodous shells, infrequent in the Lias, and which, indeed, always occur in large masses of so specially for a great part of the oolite period. About 70 species of Mollusca have been described from the British localities only, of which as many as 70 are Ammonites.

"The remains are common in some parts of the Lias, and as minute collections in all the others. In the Lias as described, these many resemble the shark, but none seem to have attained very gigantic proportions. This however was not the case with the Reptiles, which during the period in question were equally remarkable for their large size, voracious habits, and incredible abundance. Many species belonging to natural orders of these animals long since lost, were then widely dispersed; and many other species of genera now common in distant parts of the world. The Flying Reptiles is a striking instance of this phenomenon. The British Country and indeed strictly speaking the monsters named Ichthyosaurus and Plesiosaurus, are other examples."
O. punctata (Forbes), Dotted Brittle-Star. This species, first described by Edward Forbes, was found by Henry Goodaur in the stomach of a cod.
O. philomitra, Thread-Rayed Brittle-Star. The rays are very long and siliform. It is a rare species in Great Britain.
O. brachiatia, The Long-Armed Brittle-Star. This also is a rare species.
O. granulata, Granulated Brittle-Star. The rays are covered over with pointed spines.
O. Bellii, Daisy Brittle-Star. It is not uncommon on many parts of our coast, and is to be found under stones at low tide.

O. Goodauri, named after Dr. Gooadaur, who took it from a cod's stomach taken off Anstruther in Fifeshire.
O. roulea, Common Brittle-Star. Disc rounded, convex, covered with spines of various lengths; two large triangular parallel plates opposite the origin of each ray; upper ray-scales triangular, minutely imbricated; lateral plates bearing five spines each, which are much longer than the breadth of the ray. This is the most common of our British-Stars.
O. minuta, Sand Brittle-Star. This is smaller than the last, and is found buried in the sand.

(E. Forbes, A History of British Fishes.)

OphioGLOSSACEAE, Adders Tongues, a natural order of Acrogenous Plants, belonging to the alliance Filicales. They have an erect or pendulous stem, with a cavity in the middle instead of a pith, and two or more leaves, placed round it in a ring; the stalks of the leaves and the stem become blended together below; the leaves have netted veins; the spore-cases are collected into a spike formed out of the sides of the upper leaf, S-shaped, without any trace of an elastic ring; spores resembling fine powder.

These plants are a transition from Ferns to Lycopodiales. The species are most abundant in the islands of tropical Asia. They occur however in the West Indies and in the tropical parts of Africa, at the Cape, and in Tasmania. They are of little or no known use. The following genera with about 25 species belong to this order: Ophiozostis, Ophioloma, Heimioniostachys, Botryodium.

OPHIOPODIUM, [Bot. Syn. 25, 1865.]—OPIANIC ACID. [Chem. 2, 1873.]

OPIANINE. [Chem. 2, 1873.]

OPIANYLE. [Chem. 2, 1873.]

OPIE, AMELIA, the wife of John Opie, was the daughter and only child of Dr. James, an English physician of Norwich, where she was born on November 12, 1769. Her mother, a woman of considerable talent, attended to the care of her daughter's education, but she died in 1774, and the daughter assumed the position of mistress in her father's house, and became his constant companion. Handsome and lively, possessing musical talents, her company was much sought, and she enjoyed society thoroughly, but it did not tend to solidify her mind. Very early in life also she took a fancy to attend the public amusements, which she continued to frequent even at an advanced age. Her father was an admirer of the principles advocated in the early stages of the French revolution. These principles her daughter adopted, and she was present at the trial of Hornelock and his associates for high treason, of which she wrote home an account. In this whirl of social life, law, and politics, she had the judgment to form her friendships among persons distinguished for their virtues and talents, and she gave some of her leisure to literary pursuits, forming letters to D'Orbigny in this class, are now no longer regarded even as Molluscs. [Foraminifera, 2, 1873.]

PIATES. [Fishes, Fossil, p. 1.]

(Armed, Elementary Geology; Tenant, Stratigraphical

Last of British Fossil.)

OphioCEPHALUS (from 40, a snake, and kephal, head, a genus of Fishes belonging to the division of Acanthocephalia, characterized by having labyrinthiform pharyngeals, and capable of living for a long time out of the water. The species inhabit India and China. [Aramas, 1.1.]

OphioCOMA, a genus of Animals belonging to the order Echinodermata, to the family Ophiuridae, and to the tribe Ophuridae. The species are described. Brittle-Stars on account of their fragility. They are very difficult to preserve. Professor E. Forbes recommends their being placed in fresh-water, and then caught, which quickly destroys them; and after they have been in it an hour or so, to dip them rapidly in boiling water. They are then to be dried in the sun, or in a current of air. The following account is a correct one, even in parts of this essay, which was written by Mr. Forbes in his History of British Fishes:—

O. neglectus, Gray Brittle-Star. Disc round, flat, imbricated with small smooth scales; two oblong parallel touching plates opposite the origin of each ray; upper-ray scales square; lateral-ray plates bearing four or five spines each, which are equal in length to the breadth of the ray. This species is not uncommon on all parts of the British coast.

O. Ballii, Ball's Brittle-Star, was first discovered in Ireland by Dr. Ball.
"Tait’s Magazine" in 1831. In 1804 she published the novel of "Adeline de Lorraine; or, Mother and Daughter," in 9 vol., which added considerably to her reputation, and some passages of which are highly pathetic; but still she wanted art in grouping and developing her characters, and in combining her incidents. In 1805 Simple Tales, in 4 vol., were issued, in which she professed the purest and most unequivocal religion. Her feelings and ardence that steals into the heart, and language easy and simple though not always strictly accurate, there is still the same want of logical coherence; the tales want reality. The characters are ill-drawn and often extravagant, yet the "Rutland Coach," in 1806, with one or two productive interest. In 1807 after the death of her husband, she returned to the home of her father. In 1808 she published "The Warrior’s Return and other Poems," and in the following years her productions increased. A memoir prefixed in 1812 appeared "Temper," a tale in which she introduced many of her impressions of France; and in 1813 "Tales of Real Life," which however are not more real than her former tales. In 1816 Valentine’s Eve, a novel in 3 vol., was published, developing some of her religious views, now becoming more decided. In 1818 "Tales of the Heart," and in 1822 "Madeline," neither of them rising above the average of the preceding. Her next work, "Lying," appeared in 1825, and was dedicated to her father; the coast of art tales, made for her avowed purpose, with dissertations, and more decidedly than any the great defect in her reasoning powers, though all evince the most praiseworthy intentions.

Early in life Mrs. Opie had been intimate with the Quaker family of the Frys, particularly with Mrs. Fry, and through them with the Garnets. In 1814 a letter from J. J. Gurney appears to have made much impression on her mind, she committed it to the Quakers and in 1816, with her father’s consent, she formally joined their society. In 1825 her father died, but she continued to make Norwich her abiding place, varied by frequent visits to her friends, to Scotland, and the South of England. She adopted the style and dress of the society she had joined, but did not give up her literary pursuits. She still wrote occasional poems, and in 1828 "Detraction Displayed" was published. In 1829 she visited Paris, and her old political feelings seem to have revived. She wrote some verses on the tricolor, addressed to Lafayette, in which she says that at the sight of it, "I seem to feel youth’s hours return." In 1830, on the expulsion of Charles X, she again went to Paris, and has given a lively account of what she saw. In 1833, "Lays for the Dead," a volume of poems, was published. In 1835 she made a tour to Belgium and Switzerland, of which she gave an account in "Tait’s Magazine," in 1840. She continued active and beneficent for some years, contributing occasionally to periodicals, through personal, or literary, or political, or religious, or other, periods, and after an illness of some duration, she died at Norwich, Dec. 2, 1853. Her Life has been written with much care by an attached friend, Miss L. C. Brightwell, and published in the "Orchid and Broom." The Orange, the Principality of, included the town and neighbourhood of Orange in the south of France. René de Nassau, nephew and successor of Philip de Challon, prince of Orange, was killed at the siege of St. Dizier in 1544, and left his hereditary to his cousin William of Nassau, the founder of the republic of the Dutch United Provinces. After the death of William III, king of England, the principality passed to Frederick, king of Prussia, William’s eldest son, and on his succession, to Frederick-William, ceded it to Louis XIV, at the close of the War of the Hague (1710). The principality then merged in the province of Dauphiné, and is now included in the Department of Vaucluse.

** BANCHE TRIBE. [AUSTRAICIANS; CYTRUS.]

** ORCHIS, a genus of Plants the type of the natural order Orchidaceae, and belonging to the tribe Ophrydinae. The old Linnaean genus Orchis is now divided into many genera [Gynaecorchis, Orchis, etc.]; the large number of species are still retained under this division. An Orchis is distinguished by the pollen masses being divisible into lobes, which are wavy and definite in number. The anthers are wholly adnate. The genus Orchis belongs to a section of the tribe, in which all the petals are of the same size and form a rosette process between their bases. In Orchis the perianth is ringed and banded; the lip 3-lobed, spurred; the glands of the stalks of the pollen-masses are in a common pouch. The following is an arrangement of the British species according to Babington:—

* Glands of the pollen-masses separate; lip erect in sertation.
  + Bracts mostly 1-nerved; root-knobs undivided.
  + Lip, 3-lobed; lobes broad and short.

** Orchis Morio, Green-Winged Meadow-Orchis. O. maculata, Early Purple Orchis.

** Lip, 3-lobed; middle lobe dilated, bifid, and often with an intermediate tooth.

** O. ficulnea. O. Simia. O. ustulata.

** Bracts with three or more nerves; root-knobs undivided.

** Orchis flaviflora. O. maculata, Spotted Pale-flower-Orchis. O. latifolia, Marsh-Orchis.

** Glands of the pollen-masses united; root-knobs undivided.

** Lip erect in sertation.

** O. pyramidalis, Pyramidal-Orchis.

** Lip spiral in sertation.

** Orchis hieros, Lizard-Orchis.

** Babington, Manual of British Botany. ORDERS—contains objects in natural history classifications, subordinate to a Class, or sub-Class. It is, however, like many other general terms, used very loosely, especially by zoologists. In botany it is more definitely applied, and is used synonymously with Family and Tribe. In zoology Family and Tribe are frequently employed to denote groups subordinate to Orders. [FAMILIES OF PLANTS, S. 1.]

** Oregon, a Territory of the United States of North America, lies between 42° and 46° N. lat., 110° and 125° W. long. It is bounded E. by the Rocky Mountains, which separate it from the Territory of Nebraska; N. by the Territory of Washington; W. by the Pacific Ocean; and S. by the State of California and the Territory of Utah. At the census of 1850 the Territory of Oregon included the country since separated from it and formed into the Territory of Washington, and comprised altogether an area of 341,463 square miles. The area of Oregon Territory is 185,030 square miles. The estimated population, in 1857, was 42,000.

** Surface and Hydrography. The Territory of Oregon is traversed from south to north by the ranges of the Cascade and Blue Mountains, while a third range, that of the Rocky Mountains, forms its eastern boundary. The Cascade, or Coast, or Northern, range of the Sierra Nevada, is a continuous and very lofty range rising at a distance of 100 to 100 miles from the coast; and almost entirely cutting off direct communication between those portions of the Territory which lie east and west of it. Except where the Columbia, which forms here the northern boundary of the state, crosses through the range, the few passes which exist are so difficult as to be of little use to the traveller. The high peaks are from 12,000 to 14,000 feet above the level of the sea. The country west of this range is a good deal broken by spurs from the main chain. The greater part of this broken country is thickly timbered, in many parts there being dense forests of fir, pine, spruce, oak, ash, and other valuable trees, with close undergrowth of hazel, &c. The valleys and plains afford excellent sites for farming, the river courses being in some places a black vegetable loam, in others of clay and gravel. The uplands form good pastures. The harbours along the coast are, with the exception of that formed by the mouth of the Columbia, of little value; most of the other rivers have bars at their mouths, over which only vessels of little draught can pass. The coast itself is formed by steep sandy cliffs and beaches and is broken by projecting headlands which rise precipitously from the sea; the principal of these are Cape Blanco, Cape Perpetua, and Cape Look-Out, but they afford little shelter, and have mostly numerous rocks scattered about them, while everywhere a heavy surf sets in upon the beach. The Blue Mountains, which intersect the middle of the Territory, are as smoked and irregular as the Cascade and Rocky ranges. On the south-west the Blue Mountains are united with the Cascade Mountains by offsets, which form
the valleys of the Clamet and Umqua rivers, while the main chain forms the valley of the Willamette. Other offsets, diverging eastward, complete the range to the Cascade Mountain. This middle section of the state differs considerably from that of the Cascade range. The hills are barren, but in the valleys of the Columbia, Willamette, and Saptin rivers the soil is generally fertile, and in some places extremely so. The assaying of the vicinity of the Columbia and Saptin rivers consists of rolling prairie land, and affords good pasturage. The southern portion of this middle section is for the most part broken and desert, with scarcely a tree or vegetable. The general elevation of the latter is 1000 feet above sea level.

The Rocky Mountains have been noticed elsewhere. [Rocky Mountains.] They are of great altitude, and only one practicable pass has been discovered over them along the principal channel of the river; and though in some places partially timbered, it is by far the greatest part rocky, barren, extremely variable in climate, and incapable of permanent settlement.

The principal river of Oregon is the Columbia, which forms for a considerable distance the boundary between the Territory of Washington and Oregon, and joins the Columbia at the south-eastern extremity of Oregon, and is that crossed by the great stream of overland emigration to Utah and California. The country immediately west of the Rocky Mountains is everywhere broken by great spurs from the main chain, and though in some places partially timbered, is for the most part mountainous, barren, extremely variable in climate, and incapable of permanent settlement.

The Saptin, Snake, or Lewis River, sometimes called the Southern Fork of the Columbia, also rises in the Rocky Mountains and drains along the south-eastern border of the Territory, but receives from the principal channel of the river, and in some places near it, a length of nearly 1500 miles. The Saptin, in its course through Oregon receives numerous affluents, all or nearly all of which belong entirely to this Territory. Of these the principal are the Wasatucco, Fayette, and Sickly, on the right, and the Malheur on the left. Most of these rivers are of small size, and have little or no value for navigation. The Willamette, which rises on the west side of the Blue Mountains near 43° 30' N. lat., is one of the most important tributaries of the Columbia; it has a generally northern course and enters that river near opposite to sunny会长 at Oregon, considerably below where it becomes navigable; is itself navigable by small vessels for a considerable distance; and drains one of the most fertile valleys in the Territory. The rivers which rise west of the Cascade Mountains have mostly a short course and are of little service for navigation. Among these are the Columbia, the Clamet, and the Umqua.

The Umqua, which after the union of its two head branches, flows nearly west to the Pacific, into which it falls by Cape Gregory, about 45° 34' N. lat., is in its lower course a wide, shallow river, affording excellent water for navigation. The rivers of Oregon which fall into the Pacific, has its mouth obstructed by a sand bar. The Clamet, the most southern river of Oregon, is also the longest south of the Columbia; but there are few settlements along its banks, and its navigable capabilities are very limited.

Geology.—Of the geological features of Oregon only very partial examinations have been made. The mountain ranges belong generally to the igneous and paleozoic formations. Granite, trap, basalt, hornblende, and other eruptive and metamorphic rocks occur very widely, with slates, limestone, sandstone, &c. Gold is found in the sands of several of the rivers which flow from the Cascade Mountains to the Pacific; and it is said to have been also found in various places east of that range. Other minerals, especially iron, lead, and tin are also said to occur, but none of them have, we believe, been worked. We have not heard that coal has been found, though it is known to exist in Washington. Saline springs occur in the middle section of the Territory, and near its southern line in the vicinity of the Rocky Mountains.

Climate, Productions, &c.—The climate is very varied in the different sections of the Territory. Along the Pacific, and generally west of the Cascade range, it is mild and genial during the winter months. The region, on the east side of the range, is very severe; and snow seldom lies long on the ground. In the middle section the changes of temperature are much greater, and the winter much colder; but the air is more bracing, and the climate appears to be generally healthy. It is said that no dew falls in this section. In the vicinity of the Rocky Mountains the changes of temperature are extremely great and rapid. In the south-eastern part of the territory along the line of the great emigration route, the climate is very variable, but rain seldom falls, and there is little snow.

What is the principal grain crop? But a considerable quantity of oats is also grown. Maize is cultivated, but not to any great extent. The other grains are scarcely cultivated at all. Pasture is very abundant, and few other crops are raised. Small quantities of tobacco, flax, &c., are grown. Most of the European fruits flourish in the valleys of the Columbia, Willamette, &c. At present however the chief dependence of the settlers is perhaps upon the rearing of swine, which are kept for the purpose of producing the excellent pasture. Horses, horned cattle, sheep, and swine are already very numerous; and butter, cheese, and wool receive much attention from the agriculturists. Oregon has no game of the four-horned animals, but their numbers are rapidly diminishing; beavers, musk-rats, and martins are the chief which are left. Their collection is still carried on almost exclusively by the officers of the Hudson’s Bay company. In the forests bears, wolves, foxes, deer, elk, antelopes, and other game are still very abundant. Vast quantities of aquatic birds frequent the rivers in the spring and autumn. Along the coast whales are found; and edible fish are extremely abundant both along the coast and in the rivers; the salmon, especially on those which form the fine fishery of the food of the Indians. The principal fish taken are salmon, sturgeon, cod, ray, carp, smelt, and innumerable other small fish, with crabs, oysters, mussels, and other shell-fish.

At present the chief industry is chiefly confined to the production of the articles required in a very thinly peopled agricultural country, and those connected with the shipping trade. The commerce of Oregon is not minute, a considerable coasting trade being carried on with California; the export consists of large quantities of lumber, boards, flour, and provisions generally. There is also a good deal of trade carried on with New York, Boston, &c. The direct foreign trade is of little consequence.

Districts.—The state of Oregon is divided into ten counties. Salem is the political capital. All the towns are as yet but small; we notice some of the principal places; the population is that of 1850—

* * *

Sales, the capital, stands on the right bank of the Willamette; it has a small population, and little trade, but contains the state buildings, &c.

Astoria, on the Columbia, 8 miles from its mouth, population 323, is one of the oldest American trading places in Oregon, having been founded by Mr. J. Astor in 1811, but abandoned for a present time in 1826. The adjoining county, population 692, is one of the rising towns of Oregon. Oregon City, on the right bank of the Williamette River, 36 miles N.E. from Salem, population 695, is the chief town of the county of that name. The Columbia Valley is a flourishing district in Oregon. The city possesses a great amount of water power, and appears likely to become a place of considerable importance. Portland, on the left bank of the Willamette, above its confluence with the Columbia, 47 miles by E. from Salem, population 628, is also a busy and flourishing place, being the port of entry of an extensive and rich country.

The constitution was enacted by Congress in 1848; by it the right of voting is vested in every white male inhabitant of Oregon, 21 years of age, and a citizen of the United States, or who shall in the usual manner declare his desire to become one. The legislature consists of a council of 9 members, elected for three years; and a house of representatives of not less than 15 nor more than 30 members, elected for one year. All laws passed by this legislature must be submitted to Congress for approval. The governor is appointed for four years.

The coast of Oregon was visited both by the English and Spanish in the 16th century, and it has been much disputed to the mariners of which country the honor of the discovery is to be ascribed. Spanish writers claim its discovery for Ferrelo, the pilot of Cabrillo, who they assert reached 43° 30' N. lat. in 1542. All who claim the honor of the discovery, show that Drake in 1579 attained to 46° N. lat. The mouth of the Columbia, although Heceta in 1770 and Vancouver early in 1793, suspected the existence of an important river from the general appearance of the bay into which it empties itself, was not actually discovered until later in 1792, when a Captain Baker of the English
and formed but Nicolay, situated Tobacco, the fetid Vegetable tail American OUD Falconer work Twiss volatile nicious country Madrid, soverignity river Termes the published work of many Congress, 1819 to 1821 of 1814, was taken possession of by the English, but given up at the close of the war. After the treaty with Spain in 1819 the United States government first set up a claim, founded on the right of discovery, and also on their having by the treaty succeeded to the Spanish right of occupancy, to the exclusive possession of Oregon; and the claim involved the English and American governments on more than one occasion in very serious disputes. The question was not finally settled till 1866, when a treaty was concluded between the two powers, giving to the United States the entire country up to the parallel of 49° N., lat., including therefore the whole tract since formed into the territories of Oregon and Wash- ington. It was in the discretion of the United States to take the Columbia River as a line of communication with the Hudson’s Bay Territory. Oregon was constituted a Territory by Act of Congress, August 14th, 1848. (Statistical Gazetteer of the United States American Al- benz the United States; William Narrative of the United States Exploring Expedition; Green- how; Falconer; Wallace; Twiss; Nicolay, &c.) ORFILA, P., an eminent French, physician and toxicolo- gist, was born at Mahon, in the island of Minorca, on the 34th of April, 1787. He was sent to Paris to study medicine, and was naturalised in France in the year 1815. He early displayed a love for the science of chemistry, and in the application of this science to the investigation of poisons and their treatment became the most distinguished man in Europe. He was professor of medical chemistry in the Faculty of Medicine at Paris, and was subsequently for many years dean of that faculty. He was a correspondent of the Institute and a member of the Council of Hospitals. He wrote many works on the subject of toxicology, as well as on medical jurisprudence generally. His first published work was produced in 1817, and was entitled "Elements of Chemistry applied to Medicine and the Arts." This work was translated into English, and a second and third edition was published lectures on various departments of legal medicine. In 1821 he commenced the publication of a course of "Lec- tures on Legal Medicine," which was completed in 1823. Another series of lectures on the treatment of persons poisoned by opium and hydrocyanic acid was published in 1825. In conjunction with M. Lesueur, he published a work on "The Appearances presented by Dead Bodies after Exhumation, Drowning, Suffocation in Cesspools, or by Gases." He was also one of the editors of the "Nouveau Dictionnaire des Termes de Medicine, Chirurgie, Pharmacie, Physique, Chimie, Histoire Naturelle," &c. His greatest work on medical jurisprudence was his "Traité de Médecine Légale," in 4 vol., and published from 1826 to 1830. His original papers were numerous, and those on the absorption of lead, corrosive sublimate, silver, arsenic, and other metals, are most valuable contributions to toxicology. He devoted much attention to the subject of public health, and wrote a little work en- titled "Hygienie Precepts for the Use of Children in Primary Schools" (1845). One of his last works was "On the Pernicious Effects of Tobacco, and the Danger of Smoking Heavy Cigars." He died in the month of March 1853. ORIO CIEN (Canada) ORINOCO E., a natural order of Endogenous Plants, under which Lindley, in his "Vegetable Kingdom," includes the Acornia of Link and other authors. This order embraces the genera Prosopis, and Ambrosia, which are the types of three separate tribes. The genera are Ac- caxes, Liliaceae, Papaveraceae, and Araceae. It contains 13 genera and 70 species. Some of the species are used by man. Sclerococcus fusculus, the Skunk Cabbage, yields a foetid volatile oil. The Rootstocks of Calla palustris are edible. ORTHAGORISCUUS, a genus of Plectognathous Fishes, belonging to the family Gymnodontidae. On account of their round form the species are called Sun-Fishes. The genus has the following characters:—Jaws undivided, forming a cutting edge like a chisel, without spines; tail short and very high vertically; rays of the dorsal and anal fins long and pointed, both united at the caudal fin at the base. Two species of this curious genus have been taken on the British coast. O. cedrosa, the Short Sun-Fish, the Molobut, although only occasionally seen, has been taken around all the shores of Great Britain. When observed in our seas they have ge- neral!y appeared as though they were dead or dying, and hading along with the prows of ships. They are of different sizes, and of the other to view. This seems to be a natural position. O. oblongus, the Oblong Sun-Fish, Oblong Tetradon, Tana- cated Sun-Fish. This fish is larger, longer, and rarer than the last. (Yarrow, British Fishes) OSCILLATORIA. [Aloes.] OSMERUS. [Salmonidae.] OSSOIS TISSUE. [Tisuse, Organic, S. 1.] OSSOLI, MARCHIONESS. [Fulles, S. M., & 2.] OTTAWA, the capital of the Province of Ontario. [Home, N. S.] OTLEY. [Yorkshire.] OTTAWA, a city of Canada, previously called Bytown. [Browns, S. & S. to which the present notices, founded on new and original researches, are prefixed.] Bytown was derived from Colonel By, an officer of the Royal Engineers, whom the British government in 1827 commissioned to superintend the construction of the Rideau Canal. Bytown in 1854 was constituted a city, and the name was changed to Ottawa. The city is the seat of the Provincial Government, the matter was referred to the decision of Queen Victoria, who is stated to have chosen Ottawa as the future capital of the United Provinces of Canada. The situation is central for the whole of Canada, and has communication by river, canal, or railway, eastwards with Montreal and Quebec, and westwards with the Detroit River, through Kingston, Toronto, Hamilton, and Chatham. [Canada, S. 2.] Ottawa is situated at the entrance of the Rideau River, and was 87 miles W. from the confluence of the Ottawa with the St. Lawrence. At the western extremity of the city are the celebrated Chaudiere Falls, unsurpassed in America except the Falls of Niagara. The city is in Canada West, but a suspension bridge erected by the Pro- vincial Government just below the Chaudiere Falls spans the foaming mass of water, and unites Canada West with Canada East. A continuation of the Rideau Canal divides the city into Upper Town and Lower Town, entering the Ottawa by eight magnificent stone locks; and a massive bridge of cut stone, erected by the Royal Seap and Miners, crosses the Rideau Canal. At the northern extremity of the city and 3 miles above, the Rideau River pours itself into the Ottawa. The water-power for driving mills or machinery is immense on both sides of the Ottawa, and manufactures of various kinds have already been established. The city is well laid out, the streets wide and regular, the houses mostly of stone, and the principal quarters are lighted with gas. There are already several good hotels. The population now exceeds 10,000. The principal commercial outlet of the district is the port of the Ottawa, which from 18 to 18 millions of cubic feet are annually brought down the Ottawa and its tributary rivers. The Hull iron- mines, about seven miles from the city, are worked success- fully. The value of assessed property in 1856 was $2,300,000 dollars. Ottawa returns one member to the legislative Assembly. It has communication daily by steamer with Montreal and Kingston, and by railway twice a day with Prescott, on the left bank of St. Lawrence (24 miles), which connects with the Lake Champlain steamers. Ottawa is distant 296 miles W.S.W. from Quebec, 129 miles W. from Montreal, 95 miles N.N.E. from Kingston, and 23 miles N.E. from Toronto. OTTRELITE. [Michaellor, S. 1.] OTHELLO. In Shakespeare’s play, it is bound S. by Allab- bad, N. by Napani, E. by Bahar, and W. by Delhi. Its greatest length south-south-east to north-north-west is about 200 miles; its greatest breadth east by north to west by south is about 150 miles. The area is estimated.
A two-on and was the plaintiff but the defendant, he with many of the other nations that the revolution compelled the resignation of the king from the throne, and the annexation of the kingdom of Oud to the British possessions in India. The King of Oud was granted an annual pension of twelve lack of rupees (120,000). Oude forms a portion of the plain of the Ganges. The general character of the country, the capital city, Lucknow, are noticed under INDIA.

ODINOT, CHARLES NICOLAS, DUKE OF REGGIO, Marshal of France, and Grand Officer of the Legion of Honour, was born on the 2nd (some biographers state the 25th) of April, 1767, at Bar-sur-Oise. Having chosen the career of a soldier, in opposition to his father's wishes, he joined the regiment of Medec in 1785; but parental influence induced him to withdraw from the army four years afterwards. After a long interval revived his martial spirit, and, offering himself as a volunteer in 1791, his former service at once procured him a battalion. In September 1792 Oudinot defended the fort of Bisch against the Prussians, whom he repulsed with great success, and was promoted to the post of a colonel. In July, 1793, he was sent to the command of the regiment of Picardy, left vacant by its former colonel, whom the Jacobins excesses of the day had induced to emigrate. At daybreak on the 3rd of June, 1794, being stationed at a distant outpost, the Austrians fell in great numbers upon his regiment; but he, with his gun, for ten hours against a corps estimated at 10,000 strong, surrounded by the enemy's entire cavalry, he formed his men into a square, repulsed every charge of their cuirassiers, the last of which having opened a passage through them with fixed bayonets, he effected his junction with the main army, his lines never once having been broken. Instantly raised to a brigade for this intrepid conduct, he was sent to besiege Treves, and on the 7th of August 1794 captured the town by a skilful manœuvre. He next received orders to join the army of the Rhin-et-Moselle, which he did on the 14th of September. During a desperate night-attack, October 14, 1795, he was disabled by five sabre-cuts; and having fainted from the loss of blood, was taken prisoner by the Austrians. After some months in prison, he joined Moren's army in 1796, distinguished himself at the battles of Nordlingen and Donauwasser, captured several fortresses on the Danube, and was again most severely wounded at Ingolstadt. On the 26th of June 1797, having served in the campaign of Courbé before Constance, and penetrated into the town in spite of a second corps of Austrians by which it was defended. Oudinot was created a general of division, April 19, 1799, and on the 4th of June contributed effectually to the great victory of Zurich. Being subsequently appointed head of the staff in Massena's army, he shared with that commander the dangers and sufferings of the siege of Genoa. Twice during the siege he succeeded in passing through the English blockading fleet, bearing with him Massena's despatches to Schnetz. In 1800, as head of the staff under Brune, he obtained fresh honours at the battle of Pozzo and the passage of the Minio. The First Consul was so highly satisfied with Oudinot's conduct that he rewarded him with a sword of honour, to which he added one of the pieces of cannon captured from the enemy by Oudinot himself. At the opening of the campaign of 1805 Napoleon formed a picked corps of grenadiers, the command of which he intrusted to Oudinot, presenting him with the same time with the grand cordon of the Legion of Honour. At the head of his grenadiers he was the first to enter Vienna; he crossed the bridge over the Danube, though undaunted and despite the attacks of the enemy. General Oudinot was likewise present at Austerlitz. The following year he took possession of the counties of Neufchâtel and Valençay, relinquished by Prussia; and during his government conciliated the inhabitants by his liberality. After having afforded many facilities to theburghers of Neufchâtel evinced their esteem by a public address and the present of a sword. After the battle of Jena, October 14, 1806, he marched into Poland, and gained the victory of Ostrolenka, February 6, 1807. The defeat Napoleon now made him a count, to which he annexed a donation of a million of francs. But the 14th of June 1807, the morning of Friedland, was the most signal of his life. On that famous ground, with his single corps, he checked for four hours of the advance of the entire Russian army, after the sacrifice of half his men, enabled Napoleon to come up in time to win one of his greatest battles. Meeting the general after the action, Napoleon said to him, with unusual energy: "GENERAL, you are the wonder of the world wherever you are my only fear is for yourself." This incident has since afforded a subject for one of Horace Vernet's best pictures.

In the memorable campaign of 1809 the reputation of Oudinot was fully established; for after the death of Marshal Lannes, at Essling, the second corps, formerly commanded by him, was conferred upon Oudinot in these flattering terms:—"Given to you, as a general, tried in a hundred fights, in which equal skill and intrepidity have been displayed." After the battle of Wagram, Oudinot received the marshal's baton, with the title of Duke of Reggio, and a pension of 100,000 francs. In 1810, Louis Bonaparte, tired of submitting to the dictation of his imperial brother, threw him out of the empire, and appointed him Governor of Holland. Upon this defection Marshal Oudinot was ordered to take military possession of the country; he fixed his headquarters accordingly at Amsterdam. In this government he continued nearly two years, exhibiting great capacity and justice, and playing a notable part among the Dutch people by his integrity and conciliatory behaviour.

Throughout the whole of the subsequent campaigns of 1812, 1813, and 1814, the name of Marshal Oudinot reappears in every page of the honour, as one of the best-trained and most efficient of the imperial body of generals. After the first abdication he submitted to the restored Bourbons, steadfastly adhered to their cause during the Hundred Days, and was loaded with favours by Louis XVIII. and Charles X., and created a Marshal of France, the second in the hands of Angoulême in his expedition for the re-establishment of the King of Spain. He was appointed governor of the Invalides in 1842, and died at Paris, September 27, 1847, in his eighty-first year, having been upwards of sixty-four years in the French army.

The marshal's eldest son, Nicholas-Charles-Victor, the present Duke of Reggio, commanded the French army sent in 1849 to support the authority of the present pope in the Roman states. His younger son, an officer of great promise, fell into an ambush in the late wars in Africa, and was killed by the Arabs, June 26, 1853.

OUTLAWRY. Outlawry, in civil suits, was of two kinds, that on common process, and that on final process. The latter is a suit to recover a debt from a person supposed to be a defaulter, who cannot be tracked down by any legal means. The latter procedure was against a defaulter, rather than enabling a plaintiff to obtain judgment by default when the defendant does not appear, having been provided by the Common Law Procedure Act, 1852, outlawry on mesne process is by that statute abolished. Outlawry on final process may still be obtained by a judgment debtor, but there are so many other means of stripping him of all his property, that this mode of proceeding is rarely resorted to in practice.

OVE.E (Gray), a sub-tribe of the tribe Boswia and family Baculi. It includes the common Sheep and allied species. The following is Dr. J. E. Gray's definition of this family:—Forehead flat or concave. The horns are more or less spiral, wider than deep at the base, and slightly annulated in front. Two females are often heard together; the male has a more or less deep rounded subcortical pit, without any interspace; the masseteric ridge ascending high before the orbit; the auditory bulla small; the basioccipital flat, more or less expanded anteriorly by the extension of the anterior pair of tubercles, and the posterior pair of tubercles, being nearly equalized and sizable; and there are no supplemental lobes to the grinders. The hoofs are triangular, and being shallow behind, they have distinct interdigital fossae. Males emitting no stench. The genera included in this family are—

1. Ovs. Crumen distinct. Tail elongated. Skin covered with wool or adpressed hair.
2. Capra aries. Crumen distinct. Tail very short. Skin covered with thick hair, covering the wool.

Ovis aries, the Common Sheep, is subject to great variety, and many of its forms have been raised to the rank of species. Dr. Gray, in the 'British Museum Catalogue' enumerates no less than 233 varieties of this species.

In the article Snax the subject is treated chiefly with reference to farming and grazing. We here present a few of the varieties which are more interesting to the zoologist. The sheep is one of those animals which man has domesticated, and, judging by the horse, dog, cat, pig, and ox, is subject to the greatest possible variety. These varieties have been often described as species; but the most distinguished zoologists of the present day regard all the forms of Ovis as belonging to the species Ovis aries.

The following is a list of the varieties from the 'British Museum Catalogue':—

1. The Spanish Sheep. It is the Ovis Hispanicus of Linn.; called also the Merino Sheep and the British Middle-Wooleed Sheep.
2. The Common Sheep (Ovis aries rustica, Linn.; O. gallus, Dean.; O. brachyurus, Pall.; O. leptura, Schreb.) the Hornless Sheep (O. Anglicana, Linn.). Of this variety there are numerous forms, such as the Muggles Sheep and Shetland Sheep, the Southdown Sheep, the Old Lincoln Sheep, the Romney Marsh Sheep, the Cobweb Sheep, the New Leicester Sheep, the Cheviot Sheep, the Old Teeswater Sheep, the Improved Teeswater Sheep, the Dinky Sheep, the Zeland and Orkney Sheep, the Welsh Mountain Sheep, the Soft-Wooleed Sheep of Wales, the Wicklow Mountain Sheep, the Kerry Sheep, the Exmoor Sheep, the Black-Faced Sheep, the Black-Faced Heath-Sheep, and the Rams and Rosacs (Ovis Folia, Blyth).
4. The Hindi Sheep (Ovis Huma, Hodg.) the Hornless Black-Faced Sheep of Tibet. Also a native of Nepal.
5. The Cego (Ovis Cagia, Hodg.) the Kago, or Tame Sheep of Cabul region; the Cego Sheep of Grey. A native of Nepal.
7. The Curumbah Sheep of Mysore.
8. The Sheep called Gfdr in India.
9. The Dukham (Deccan) Sheep.
11. The Brazilian Sheep.
12. The Demerara Sheep.
15. The Guinea Sheep (Beller et Brevis des Indies, Buffon; O. A. Guineensis, Schreb.).
17. The Shyamb mixture of Myr isole.
18. The Sheep of Syria, of Buckingham.
19. The Pezhan Sheep, of Bennet, from Tripoli.
20. The Sheep of Ceylon; the Sheep of the Hair of the Shibboras, Capra Cretensis, Brison; Strepsicerus Cretica, Beach; Beller et Brevis des Vallesch, Buffon; Zoczk of the Austrians; Wachall Sheep of Beawi.
21. The Long-Tailed Sheep of Russia (O. longicaudatus, Brison; O. Dehlericus et Tedericans, Pallus).
22. The Broad-Tailed Sheep (O. longicaudatus, Erlz, Geoff., Mem. Egypt); Lesson, Comp. Buffon, x. 12; O. lactuca playthera s. Arabica, Linn.; O. Turica, Charlet; Bucharian Sheep (O. Bucharica, Pallus); the Tibetan Sheep (O. Tibetana, Fisher); the Cape Sheep (O. Capensis, Erzleb); the Sheep of Belkak.
23. The Many-Horned Sheep (O. polycrurus, Linn.). It is also called the Four-Horned Ram, and the Dumba Sheep. It is a native of Nepal.
24. The Puchia, or Hindustan Dumba (O. puchia, Hodgson).
25. The Short-Tailed Sheep (O. brachyura borealis, Pallus). It is a native of Northern Russia.
26. The Sheep of Tartary. They are said to eat bones like a dog.

The genus Capriose embraces the following species:—

C. F. Horn, the Sha, or Koeh. It is the Mountain Sheep of the north of India, and is found in Tibet.
C. orientalis, the Armenian Sheep. It is the Agrocerous Musimon of Pallus; the Ovis Musimon of Brandt. It is a native of Armenia.
C. musimon, the Mouffon. This animal has a multitude of synonyms. It is the Capra Ammon of Linneus, and the Ovis Musimon of other authors. It is the Wild Sheep and Siberian Goat of Pennant. It is found in Cypris, Candia, and Corsica. For figure of Mouffon, see Sizar, p. 359.
C. Ammotragus, A. Fragilis, the Aondad of the Moores of Babar and the Kabesh of the Arabians, is a native of North Africa. For figure, see Coarri, 'O. Cretensis, the Taye or Big Horn. It is the Osa monimus of Geoffroy, and a variety, the O. Calaminus of Douglass. Dr. Gray says it is probably the same as the Amon of Northern Siberia.

There is only one species of Pavo, the P. Nahoor, the Nahoor Nervar or Se. It is a native of Nepal.
C. Argali, the Argali. It is the Agrocerous Argali of Pallus, and often confounded with the former. It is a native of Siberia. Dr. Gray says of this species:—

"The Sheep of the Ubbars, or Wild Sheep, seldom or never cross the Hemachai, the Indian side of which range is the special habitat of the Nahoors, while to the north and west beyond the Thibet our animal is replaced by other species, so that Thibet may be considered as the special habitat of one species (Ovis Ammonoides), and the plateau north of Thibet as far as the Altai of another (Ovis Ammon), cited as types of the true ovin form; and it may be added, that the six sorts of tame sheep of Thibet and the Sub-Himalayas
all without exception exhibit the essential characters of that form.

"There are several species that may be confounded under this head: the Siberian Argali is found in the most northern part of that country, and it is probably different from the Himalayan animal; but I have not been able to discover any difference between the specimen received from Mr. Hodgson and 3, which were sent from Siberia by the Russian naturalist."

OVER. [Cimbris.] OVERSEER. The duties of overseers have by recent statutes been extended and modified in various matters of detail; but an outline of their duties given under Overseers, vol. xviii, p. 70, is still sufficiently accurate, no alterations being of sufficient moment to call for comment.

OVERTON. [Flintshire.] OVERTON, DR. A.DOLF, was born July 24, 1782, in the city of Hamburg. He was educated at the University of Bonn, and afterwards at the University of Berlin, where he took his degree. His favourite study was geology, which he pursued for some years. In 1840, when Mr. Richardson, at the expense of the British government, was preparing to undertake a journey to Lake Tchad, in Central Africa, Dr. Overweg and Dr. Heinrich Barth were selected to accompany him, in order to make scientific observations. An account of this expedition is given under the year 1852.

Overture died of an attack of fever, Sept. 20, 1852, at Madarari, about ten miles east from Kuka, and near the western shore of Lake Tchad.

Oxalis. [Oxalid.] OX-LOH. [Powdler.] OX-TONGE. [Helmithia, S. 8.]

Oxycoccus, a genus of Plants belonging to the natural order Ericaceae.

O. pauciflorus, the English Cranberry, is found wild abundantly in swamps of Norfolk, Lincolnshire, and many other parts of England, always by the side of little rills, and not among stagnant water; it has slender trailing thread-like shrubry shoots, clothed with tiny linear leaves, and has a 4-petalled pink corolla with the segments sharp-pointed and turned back. The fruit is a round an'tere red berry, which makes excellent tarts and one of the many kinds of maralade. The Russian cranberries of the shops are borne by this species. They are not gathered till after the disappearance of snow.

Near St. Petersburg the cranberry plant is so common, that the snow is stained crimson by the berries crushed to pieces by the passage of sledges over them.

Oxyrhynchus, the American Cranberry, is very like the other, but its leaves, flowers, and fruit are larger; and the latter has a more medicinal taste. It is imported from the United States in boxtops, in considerable quantity, and used for the same purposes as the other; but it is considered of inferior quality.

Oxygen. [Chemistry, S. 1.] Ozokerite. [Mineralogy, S. 1.]

Pacinian corpuscles. [Tissues, Organ, S. 1.] PAGNAS. [Pachyderm.] PAINSHAW. [Devonshire.] PAIXHANS, HENRI-JOSEPH, General of Artillery in the French army, was born January 22, 1783, at Metz, in the French department of Moselle. He received instruction in the Ecole Polytechnique, and having entered the artillery, rose by successive gradations to the rank of Colonel, and ultimately of General. He was also elected a member of the French Chamber of Deputies, and spoke occasionally on subjects connected with the army and navy. Several of his speeches were afterwards connected with his valuable works quoted hereafter. General Paixhans died August 19, 1854, on his domain of Jouy-sur-Arches, near Metz.

General Paixhans made important improvements in the construction of heavy ordnance, and also in the projectiles, in the carriages, and in the mode of working the guns. The Paixhans-guns are especially adapted for the projection of shells and hollow shot, and were first adopted in France about the year 1824. Similar pieces of ordnance have since been introduced into the British service. They are suitable either for ships of war, or for fortresses which defend coasts.

The original Paixhans-gun was 9 feet 4 inches long, and weighed nearly 74 cwts. The bore was 29 centimetres (9 inches nearly). By judicious distribution of the metal it was so much strengthened about the chamber, or place of charge, that it could bear firing with solid shot weighing from 86 to 88 lbs., or with hollow shot weighing about 60 lbs. The charge varied from 10 lbs. 12 oz. to 18 lbs. of powder. General Paixhans was one of the first to recommend cylindro-conical projectiles, as having the advantage of encountering less resistance from the air than round balls, having a more direct flight, and striking the object aimed at with greater force, when discharged from a piece of equal calibre, whether musket or great gun. As large ships of war, particularly three-decked ships, offer a mark which cannot be missed, even at considerable distances, and as their weight and size make the long and strong 12-pounder shell project horizontally could not pass through them, an explosion taking place would produce the destructive effects of springing a mine, and far exceeding those of a shell projected vertically, and acting by concussion or percussion. In accordance with these views, General Paixhans recommended the use of smaller ships carrying heavier guns suitable for projecting shells and hollow shot; and advised his government to avoid the construction of large ships, and the equipment of any ship for shell-firing to such an extent as to expose her the greater part of her crew by the explosion of her guns in action.
PALARUS. [Laridnre.]
PALEA. [Cataphidum.]
PAINON, PALEMONIANs. [Sriimt.]
PALM-TREE WINE. [Bolus.]

Palmblad, Wilhelm Fredrik, a Swedish writer of considerable note, was born on the 5th of December, 1788, at Ljusned, near Soderkoping, the 11th child of a military commissary, who had procured the situation of Kronofogde, or collector of taxes. The property of the family must have been considerable, as young Palmblad, when a student at Upsal, and before attaining his majority, bought, in conjunction with another student, the university printing-office, and forthwith commenced a series of publications, which had for their object to effect a revolution in Swedish literature. Many of the works published during this new periodical by Atterbom and Palmblad, appeared in July 1810, within a month of his taking possession of the printing-office; at Christmas of the next year appeared the first number of the 'Poesiakalender,' the earliest Swedish annual, and in the beginning of 1813 the first of the 'Svenske Litteratur Tidning,' or 'Swedish Literary Gazette.'

The 'Tidning,' which lasted for eleven years—up to 1824—was the most long-lived Swedish literary periodical on record; while the Danses could, in 1824, boast of one that had outlived a century. Its circulation, we are told by Palmblad, was never upwards of 200, and averaged about 100; yet it had a great influence on the cultivation of Swedish literature. It excited the astonishment of the public, and was attacked by all schools and sects of literature, which at that time was entirely French in its models and its opinions; and on one occasion the Rector of the University of Upsal summoned Palmblad, as the universal printer, to inform him, that if his periodical contained any more unfavourable criticisms upon the Swedish Academy, his privilege would be withdrawn. The Swedish Academy had been founded in imitation of the French Academy by Gustavus III., who was accustomed to declare that there were but two things held in higher admiration—namely, the German language and tobacco. One of the chief objects of the new school—which from the title of its first periodical, the 'Phosphores,' became known by the name of the 'Phosphores'—was to introduce the Swedish public to some knowledge of the masterpieces of Goethe and Schiller; and in spite of the efforts of the Academy, which in the first instance looked upon the Phosphorists as a body of continuations rebels, the result was general though not local success. Afterborn, the chief leader of the party, was indeed too fantastic in the character of his own writings to become unconditionally popular; but before the close of his career he was elected a member of the Academy of which he had been the assaliant. Tegner and Gjeller, who had censured some of the proceedings of the new party, were violent and interlaced, were themselves much more averse to the principles of the old; and, finally, an almost complete revolution took place in the aspect of Swedish literature.

Palmblad was born in both the student life and the press, continued to contribute to the periodicals that successively arose on the ruins of each other, the 'Journal of the Swedish Literary Union,' 'Svea,' 'Skandia,' 'Mimer Frey,' &c., and also pursued an academic career. In 1823 he became 'Docent' or tutor of Swedish history at the university, in 1827 assistant professor of geography and history, and in 1830 professor of Greek. Many of his numerous works are on the subjects which occupied him as professor: his 'Handbook of Physical and Political Geography' (5 vols., Upsal 1826-27) is of high reputation, and has been translated from Swedish into German. His poetical translations of Sophocles (1841) and of Aeschylus (1849) are of some note. The poetical works of Greek however he often felt an inclination to return to an easement of writing novels, and his 'Falkenvard Family,' (2 vols., Orebro, 1844-45), and 'Aurora Konigmark' (6 vols., Orebro, 1846-61), met with much success, and were translated into German. The work known as 'Remains,' which, according to the great 'Biographical Dictionary of Celebrated Swedes,' which he left incomplete at his death, on the 2nd of September, 1855.

This dictionary, 'Biographiskt Lexicon over namnligna Svenska Män,' commenced in 1833, was interrupted at Professor Palmblad's death, but is now again in progress. The last volume which we have seen is the twenty-sixth, which brings it as far in the alphabet as the end of the letter W. It embraces the names of the living as well as the dead, and a considerable portion of the information it contains is derived from private communications or from personal observation, and embodied for the first time in its pages. It aspires to give an account of every Swedish name of note, and a list of the works of every Swedish author. The only other biographical dictionary of the same kind that the Swedish possesses, is that of Gzelius in three volumes, and a supplement commenced in 1778. But the new work is on a much larger scale in every way than the somewhat meagre complication of Gzelius. Many of the lives are given in considerable length, several are autobiographies, the account of Palmblad himself. On the other hand, some of the lives of living persons are little more than a string of dates, with a record of promotions; but such inequalities are of course unavoidable in a work of the kind. The body of the work is generally known as 'Palmblad's Biographical Dictionary,' but does not bear his name in the title, and in his life he speaks of himself as only one of the editors, and the author of a considerable number of the lives. It is one of the most indispensable books in a Swedish library, and will, as it comes to be more generally known, do much to spread abroad the knowledge of the illustrious names of Sweden.

Palmipes, a genus of Star-Fishes belonging to the tribe Gosinidiae and family Astroidea. The body is thin, flat, and pentagonal, and covered above and beneath with fasciculated spines; avenues bordered by longitudinal fasciculi of spines; suckers visceral. The species of this genus are not numerous.

P. Branchipes, the Bird's-Feet-Star-Sea, is a British species. It has broad ample sub-acute lobes. Colour white, with red rays and border. It is the thinnest and flattest of all its class. It ranges from the Arctic seas to the Mediterranean.

(Forbes, History of British Star-Fishes.)

Panarla. [Lapri Islands.]

Pangiacce, a natural order of Dichotomous Exogenous Plants. This order embraces three genera, the species of which are trees with alternate stalked entire leaves, polyetalous axillary monocious flowers, with scales in the throat of those bearing pistils. The stamens are five, the seeds large and oily. Dr. Lindsley says, 'What the distinction is between these plants and Papyses, except that the last are monopetals, and have no folial scale sides in the g flowers, it is hard to say.

The species are found in the hotter parts of India. They are all poisonous. The natives of India employ extensively in medicine the seeds of these plants, which are known by the names of Chaulmouga and Patalmouga. The genus Hydnocarpus, formerly referred to Phocourosaroe, belongs to this order.

Panias. [Panias.]

Panorne. [Planina.]

Panorbes. [Crassidiom.]

Papanastes. The area and population of the Papal States are distributed as follows over 20 provinces, 6 of which, called Legations, are governed by a Cardinal legate, and 14, called Delegations, are administered by dignitaries of lower degrees:

adapted to the requirements of the profession in the present century. He retained his position as president till his death, on the 24th of December, 1856, and was succeeded by Dr. Thomas Mayo.

Dr. Par's devoted much attention to the study of the physical sciences generally and astronomy. When in Cornwall he conferred a great benefit on the mining population by suggesting that the bar used for moving portions of rock, should be covered with copper, which prevented the iron of which it was composed from striking fire against the rock, and which by igniting charcoal used in blasting, often produced the most serious ill consequences. In London he became an early member of the Royal Institution, and was the friend and biographer of Sir Humphry Davy. His 'Life' of Davy was published posthumously by his widow. He wrote anonymously a little work of great merit, and which has gone through many editions, entitled 'Philosophy in Sport made Science in Earnest.' He was a Fellow of the Royal Society, and a Doctor of Civil Law of the University of Oxford.

PARLIAMENT, IMPERIAL. The alterations which have been made in the law relating to the election of members of Parliament, and the constitution and powers of election committees, have been mentioned under Elections.

PAPANE, E. Meiser's name for the family of Plants called by Linneæus, N. Scand. Brown named this tribe, after Nicæum, Nicæa, which is now most commonly adopted. [NL: Nicæa]

PARRY, SIR EDWARD, Knight, Rear-Admiral of the White, was born December 19, 1790, at Bath, in Somersetshire. His father was Caleb Hillier Parry, M.D., a physician of some celebrity. His mother was the daughter of John Rigby, Esq, of Lancaster.

Edward Parry was the second of five sons called when a boy (and generally known afterwards as Sir Edward Parry), was educated in the grammar-school of the city of Bath, where he attained a knowledge by no means contemptible of the Latin and Greek languages. His first object was medicine, and he intended him for the medical profession, but in 1803 Miss Cornwalls, a near relative of Admiral the Hon. William Cornwalls, then in command of the Channel fleet off Brest, induced them to change their purpose. She thought he had the qualities suitable for a naval officer, and that her influence would suffice to float him off comfortably. As he had no objection to make trial of a sailor's life, in June 1803, through the kindness of Admiral Cornwalls, he was appointed a first-class volunteer on board the Vindictive. After the ship was captured, and he was taken prisoner, he was made a midshipman. The Vindictive was then sent on to the Mediterranean, and the six days' passage was occupied in teaching Parry the rudiments of navigation.

Parry, once a volunteer, was now a midshipman. He was the first pupil of Mr. John Franklin, then a midshipman in the same ship. His progress excited the notice of the officers, particularly of Mr. John Barraclough, who had charge of midshipmen. Parry showed a great force of mind and activity, and was induced to read and study. He had a great capacity for language, and was well suited to the life of a sailor. In 1808, when he was 17, Parry was made a midshipman on board the Tribune frigate, as a midshipman. The Tribune was employed about two years in cruises off the French coast; but in the spring of 1808 Captain Baker was promoted to the Tribune to the Vanguard, 74, which belonged to the Baltic Station. Parry, who had been assigned to the Vanguard, was then transferred to the Twins, and parried off the Downs in December 1809, and Parry obtained his commission as lieutenant, January 6, 1810. Early in February the same year he proceeded to Sheerness to join the Alexandria frigate, which was about to sail on service in the Baltic, and was afterwards employed in the northern seas in protecting the Epiphanes whale-fishery. During that period Lieutenant Parry was a good deal employed in making astronomical observations, and in improving the Admiralty charts of the Baltic. In January 1811, Parry was appointed to the Lady Nelson, and proceeded to Halifax in Nova Scotia, to join the La Hogue, 74. Great Britain was then at war with the United States, and Lieutenant Parry having joined the La Hogue in the summer of 1813, in the spring of 1814 was engaged in a successful post-exposition, which ascended the St. Lawrence to Connecticut as far as Petitpaine Point, and destroyed several privateers and other vessels, in all 87, valued at 50,000L, with the loss of only two men killed.

After the Peace of Ghent he returned to England, but Lieutenant Parry, in hopes of preferment, remained on the North American station in the Maidstone frigate, and afterwards in the Ardent, 64, the Carron, 20, and the Niger, 36. He continued on the North American station without interruption, until the 1st of July 1817, when he was appointed to the schooner Lynx, and proceeded to the Cape of Good Hope. The voyage was in consequence of his father having suffered a severe attack of paralysis. While on the North American station in the La Hogue he drew up a little work for the use of the junior
officers of the fleet on that station, and distributed it in manuscript. It was afterwards printed, under the title of "Nautical Astronomy by Night, comprehending Practical Directions for knowing and observing the Principal Fixed Stars of the Northern Hemispheres; to which is prefixed a Short Account of the most interesting Phaenomena in the Southern Hemisphere; the whole illustrated by several Engravings," 4to.

Lieutenant Parry was desirous of joining the expedition to the river Congo in Africa, but owing to his having been detailed for some time, he did not proceed until the end of 1817, when it was too late. Meantime, in consequence of a report that the Arctic seas were then much less encumbered with ice than usual, the Admiralty had fitted out two expeditions for those seas, one under Captain Bouch and Lieutenant More, and the other under Commander John Ross for the purpose of exploring Baffin's Bay, and ascertaining the probabilities of a North-West Passage from the Atlantic to the Pacific. Parry having heard of these expeditions, wrote to request employment, observing that he was "ready for hot or cold, Africa or the Arctic regions." When he arrived in London, he was introduced to Mr. Barrow, secretary to the Admiralty, who soon afterwards appointed him to the command of the Hecla, under Commander John Ross in the Isabella. The Isabella, followed by the Alexander, left the Thames at the end of April 1818. On the 19th of August the two ships were off Smith's Sound at the northern extremity of Baffin's Bay. They then turned southward, and the Hecla was ordered to proceed towards Jones's Sound, and on the 30th reached the wide opening of Lancaster Sound. The water was deep and free from ice, and on the following day both ships under a press of sail were steering westward up Lancaster Sound. Parry was full of expectation, as well as all the crew on board the Alexander, when suddenly the Isabella tacked, turned her head eastwards, and rejoined the Alexander. Both vessels then traced their course, and Lancaster Sound was left behind. Consequently, the Hecla, which had been ordered to proceed to the Croker Mountains, passing the passage to the westward. The two vessels entered the Thames on their return in November of the same year.

Lieutenant Parry's opinion is that there was an open passage up Lancaster Sound, and that the Croker Mountains were a mistake, though privately expressed, was soon known at the Admiralty. He had interviews with Mr. Barrow, and was introduced to Lord Melville; and a second expedition for the discovery of a North-West Passage having been resolved upon, the Hecla and Gipsy were taken into dock at Deptford to be repaired and strengthened for service in the Arctic seas. Parry was appointed to the command of the Hecla and of the expedition. Lieutenant Liddon being placed in command of the Gipsy, the Hecla proceeded for the Thames on the 11th of May 1819, and having sailed up the eastern side of Davis's Strait and Baffin's Bay, on the 21st of July they were in 73° N. lat., nearly opposite to the entrance of Lancaster Sound, being bound to the westward, in the direction of the ice to the west intercepting their passage to it. Through these masses however, with excessive labour and frequently exposed to great danger of being crushed, the ships forced their way; and on the 28th of July reached open water on the western side of the ice, having passed through eight or nine miles of it. They entered Lancaster Sound, and sailing westward through the imaginary Croker Mountains, on the 4th of September crossed the meridian of 110° W. long., in 58° 42' N. lat., which they were entitled to a reward of 5000l., offered in an order in council to be bestowed on his Majesty's subjects as might succeed in penetrating thus far to the westward, within the Arctic Circle. Parry gave the name of Barrow's Strait to the continuation of Lancaster Sound; discovered Mel's island, having on its northern side, and from its vicinity described the high coast on the southern side, which he named Banks' land, which but Sir Robert McClure has since ascertained to be the northern side of Banks Island. Parry also discovered Prince Regent's Inlet and the Wellington Channel, and accompanied as far as the 54° 43' W. long. On the 26th of September, after three days of arduous labour in cutting a channel, with the thermometer nearly at zero, both ships were got safely into their stations, lying on the north-west coast of Melville Island. There the ships remained frozen up, with the sun entirely below the horizon from the 11th of November to the 7th of December, and were not released from the ice till the beginning of August 1820. After making several attempts to advance farther westward, they were compelled to return to England, and entered the Thames on November 1820. On the 4th of the same month Lieutenant Parry was promoted to the rank of commander; and several other rewards and honours, F.R.S., &c., were bestowed upon him.

An expedition was soon afterwards made for another expedition. Captain Parry received a commission, dated December 30, 1820, for the Fury, with Captain G. F. Lyon under his orders in command of the Hecla. This expedition was much less fortunate than the former. It sailed from Plymouth on the 1st of June 1821, and having embarked his Majesty's ships on the 8th of October the ships were frozen in at Winter Island, where they remained till the 2nd of July 1822. They were then released, and sailed northward up Fox Channel. Having discovered the Fury and Hecla Strait, the ships were again frozen in on the 31st of October at the island of Igloolik, at the eastern end of Fury and Hecla Strait. There they remained till the middle of August 1822, when they commenced their voyage homewards, and entered the Thames on November 10, 1822. Captain Parry's "Narrative of a Second Voyage for the Discovery of a North-West Passage," published in 1825, was rewarded by his Majesty's commending him for his desert. In December 1823 Captain Parry was appointed Acting Hydrographer to the Admiralty.

The Hecla and Fury were soon afterwards refitted for another Arctic voyage, the Hecla commanded by Captain Parry and the Fury by Captain H. P. Hoppner. They sailed from the Thames on the 8th of May 1824, passed the following winter at Port Bowen in Prince Regent's Inlet, and remained there frozen up from the 28th of September till the 10th of February 1825. At about that time the Fury was wrecked, and the Hecla reached England, with a double ship's company, in the following October. Parry's "Journal of a Third Voyage for the Discovery of a North-West Passage" was similarly published, in 4to., in 1828.

After his return Captain Parry was appointed Hydrographer to the Admiralty, and continued to perform the duties of the office till the 10th of November 1828. Having then proposed a plan for reaching the North Pole, and obtained sanction for it, he was again appointed to the command of the Hecla for that purpose, and sailed from the Thames on the 3rd of April 1827. The Hecla was secured in Trenen Berg Bay, on the north coast of Spitsbergen, on the 21st of June; and on the 22nd two flat-bottomed boats, each with a crew of ten men, were sent to the north-west coast, and proceeded northward. One boat, with twelve men, was commanded by Captain Parry; the other, with the same number of men, by Lieutenant James C. Ross. The remainder of the crew, under the charge of Mr. Gore, were left on board the Hecla. With excessive labour the boats were paddled through the water and dragged over the ice till they attained the latitude of 83° 45', which is the nearest point to the North Pole ever yet reached. Finding them that a correct was taking them southward as fast or faster than they could advance northward, they commenced their return, and reached the Hecla on the 21st of August, after an absence of sixty-one days. The Hecla began her return voyage on the 28th of August, and Captain Parry reached Baffin's Bay on the 17th of September. Captain Parry had ascertained Parry's arctic labours in the Arctic regions. His "Narrative of an Attempt to reach the North Pole in Boats fitted for the Purpose," and attached to his Majesty's Ship Hecla, in the Year 1826, was rewarded by the authority of the Duke of Clarence, then Lord High Admiral.

Captain Parry resumed his situation as hydrographer; but, as his health was considerably from close attention to the duties of his sedentary occupation, he occupied the offices of Secretary of the Royal Geographical Society, and Governor of the New South Wales. Previously however to his departure from England, he received the honour of knighthood from George IV., together with Sir John Franklin, April 25, 1829; and Sir John Franklin was also invested with degrees of the C.L.C. on the 30th of December by the Universities of Oxford and Cambridge; Sir Edward sailed from the Thames for Australia on the 20th of July, and reached Sydney on the 13th of December. His
residence as commissioner was at Port Stephens, about 90 miles north from Sydney. He entered the Thames on his return, with his wife and family, in November 1834.

In March 1835 Sir Edward Parry was appointed an Associate Justice of the Supreme Court of New South Wales, but his health giving way under the pressure of work, he resigned the office within a year. In 1837 he was appointed to organise the packet-service between Liverpool and Ireland. From the 19th of April 1837 to the 31st of December 1846 he was at a distance from his family, and resided at Rosario, Paraguay. He then retired from active service, receiving the appointment of Captain-Superintendent of the Royal Clarence Yard and of the Naval Hospital at Haslar, near Portsmouth. On the 2nd of August 1847, he was made a Companion of the Order of the White. At the end of 1853 he received the appointment of Lieutenant-Governor of Greenwich Hospital, a situation which he retained till his death, which took place on the 7th of July 1866, at Bens in Germany, where he had been residing for the benefit of his health. His body was brought to England, and interred in the cemetery at Greenwich.

Sir Edward Parry married, October 83, 1826, Isabella Louisa, fourth daughter of the Lord Stanley of Alderley. She died March 18, 1851. On the 19th of April 1841 he married the daughter of the Rev. Robert Hankinson of Walpole in Norfolk, and widow of Samuel Hearne, jnr., Esq. By his first wife he had two sons and two daughters, and by his second wife, who survives him, two daughters.

He was a member of the House of Commons, and recently Memoirs of Rear-Admiral Sir W. Edward Parry, Knt., F.R.S., &c., Late Lieutenant-Governor of Greenwich Hospital, by his Son, the Rev. Edward Parry, M.A., of Balliol College, Oxford, and late Tutor in the University of Durham, &c. 6vo. Longman, Hurst, Rees, Orme, and Brown.

PARSONSTOWN. [Bran.]

PARTNERSHIP. [Joint-Stock Companies, S. 2.]

PASENG, GOAT.

PASKIEVICH, IVAN FEDOROVICH, a Russian field-marshal, Prince of Warsaw, and Viceroy of Poland, was descended from a family of the Greek religion, bearing the name of Paskiewicz, which was driven from Poland in the 17th century by the persecution of the Jesuits. He was born on the 19th of May (new style) 1781, at Pulwara or Polwia, famous for the battle which decided the ascendency of Russia over Sweden. After receiving his education at St. Petersburg, he held the appointment first of page and afterwards of aide-de-camp to the Emperor Paul, and subsequently to the Emperor Alexander. He first saw service at the great battle of Austerlitz in 1805. In 1806 he was sent with the Russian ultimatum to the Porte, and in those days of Turkish harrieries owed to his own determination and firmness, the Sultan's public conduct to the country. Not long afterwards he was taken up for dead from the ditch of Brailov, where he had mounted to the assaut: he was promoted as a reward to the rank of colonel, and from that time his advancement was rapid. In the great campaign against Napoleon the Russians adopted the system of outward-looking batteries being put in command of a division, which at first amounted to only 4000 men, but subsequently rose to 80,000, took an active share in the triumphant campaign in Germany, and was one of the captors of the Palais. After the peace he accompanied the Grand Duke Michael on a three years' tour through Europe. On the accession of the Emperor Nicholas in 1826 he was named successor to Yermolov, in command on the Persian frontier, at the time of the outbreak of the war. The account of his conduct during the war, and the result of it, that it was doubted by the Russians, probably for the first time in Russian history, if a subject would yield obedience to the emperor's orders, and it even occasioned some surprise that "the King of the Caucasus" allowed himself to be dethroned so easily. Paskievich, on the 26th of September 1826, defeated the Persians under Abbas-Mirza at Elisabethopol; later in the same year he crossed the Araxes; early in the next year he conquered all Persian Armenia, and on the 23rd of December 1828, he was made Continental Grand Commander by the emperor's order bore the name of Paskievich-Krivansky to commemorate the exploit. The peace with Persia, established by the treaty of Turkmanchay (32nd of February 1828), was almost immediately followed by war with Afghanistan, and the following year Eremov, receiving in reward the title of field-marshal. A year of desultory warfare against the Circassians in 1830 was followed in 1831 by the campaign against the Poles, to whom the name of Paskievich sounded as that of a countryman. He took the command of the Russian army after the death of Diebitsch, and, more fortunately than his predecessor, was soon able to announce the fall of Warsaw. Raised to the rank of Prince of Warsaw, and made Governor-general of Poland, he was the subject of the organic statute of the 26th of February, 1834, which unites Poland to Russia, and for the next sixteen years carried out his plan of subjecting the country, one of the main points of which was the conversion of Warsaw into a strong fortress against any enemy. By his success against an invading Austrian army. He succeeded so well, that 1848 passed over Russian Poland without a revolt, and in 1849 the Emperor Nicolas could spare him to crush the Hungarians. As on former occasions, he now did not make use of the objects of military critics, but with his usual good fortune he was enabled to commence a deep draft in the emperor in August with the words, "Hungary is at your feet." In 1850 the jubilee of his fiftieth anniversary in the service was celebrated with great rejoicings at Warsaw, and on this occasion the Emperor of Austria and the King of Prussia nominated him a field-marshal in their respective armies. This was the culminating point of Paskievich's long career. When the recent war broke out between Russia and Turkey, the veteran general summoned to the field, though, as is said, against his will. He planned the campaign against the Turks, which terminated disastrously for the Russians in the repulse of their attack on Siliistra, and in that repulse Paskievich himself was wounded. After a long and tedious illness he expired at Warsaw on the 29th of January 1866.

Marshal Paskievich was married to a lady who was a relative of Emperor Alexander, his companion in some of his Persian campaigns, and had by her four children, one of whom, a son, Fedor, is a colonel of the Russian guards, and has also made his appearance as an author. A separate life of the Marshal in French was published by Teosey at Paris in 1835.

PASSEY. [SPARROW.]

PASSIFLORACEE, Passion-Flowers, a natural order of Hypogynous Exogenous Plants. This order is included by Lindley in his alliance Pedaloide. It is characterised by possessing peltate or spatulate corollina flowers; ovary hypogynous, flower petals; stamens on the stalk of the ovary; simple terminal style; spiralled seeds; and stipitate leaves. The species are herbaceous plants or shrub, usually climbing, very seldom annual. Considerable difference of opinion exists among botanists as to the real nature of the floral envelopes of this remarkable order. Jussieu and De Candolle, regarding the petal called petals as a second row of sepals, have made the order a sub-order of concerning, some of the species of the second row of floral envelopes as petals, and made it poly-petalone. Lindley makes the affinity of this order with Samyleaceae, Capparidaceae, Malacertibecrane, and Papaveraceae. Most of the useful properties of this order are included in the common genera of Passiflora, the tropical species of which the West Indian climber, is said to be anthelmintic and diaphoretic. Besides the fruit of several species of Passiflora, the fruit of Tanaclor mollissima, T. trifascia, T. speciosa, and Passiflora adusta are all of them edible. The species are principally found in South America. There are 10 genera and about 86 species.

PASSION-FLOWERS. [PASSIFLORACEE, S. 2.]

PATELEY-BRIDGE. [Yorkshire.]

PATTERSON, C. S. [Paten.]

PAULUS, HEINRICH EBEBARD GOTTLOB, was born on September 1, 1761, at Leonberg, near Stuttgart. He first proposed devoting himself to the study of medicine; but becoming attached to the sect of Pietists, he soon turned his attention to the study of mathematics, and afterwards he pursued his studies. By the liberality of the Baron von Palm he was shortly enabled to travel in France and Saxony, in order to examine the state of education. He afterwards studied the Oriental languages at Leyden, and
then again assisted by Palm, proceeded to London and Oxford to prosecute his studies. On his return to Germany he contributed in 1790 professor of the Oriental languages in the University of Jena. Here he occupied himself in illustrating and explaining the Old and New Testaments in a philological-historical manner, which first developed to the German public in 1788–90, in several books, and in 1793, with others. To these succeeded his "Philologisch-kritischer und historischer Commentar über das Neue Testament," which was given to the world in 4 volumes in 12mo, which he corrected and added much to his reputation. In 1793, on Döderlein's death, he was created professor of theology, but on account of his health, he removed in 1803 to Würzburg in a similar capacity, where he became also a chancellor of the consistory and president of the synod. To obtain that latter theological professorship at Würzburg, he was sent to inspect the state of the schools and churches, in 1806 to Bamberg, in 1809 to Nürnberg, and in 1811 to Ansbach. In this year a call to the chair of exegesis and church history in the University of Heidelberg restored him to his academical life, and to his literary activity. In 1814 the endeavours then being made to give a constitution to his native state of Würtemberg excited his attention, and in 1819 he commenced writing in a popular way, and on a considerable scale, his essays upon important subjects, such as proselytizing, under the influence of the Papist government on the national Roman Catholic Church of Germany, and others, gained great applause. In this he continued to write till 1829. As a theologian, he is distinguished by the intercourse of his mind with other literati of the age, and by his attempts against a one-sided nationality and a speculative deviation from the original doctrines of Christianity, as from mysticism and Jesuitism. With these ideas he began in 1825 a theological year-book, called "Drucke aus dem Empire," published from 1825 to 1829, and another journal called "Kirchenbekenntnungen," published in 1827. Among his other numerous writings we may mention "Memorabillen," published in 1791 to 1794; "Sammlung der Merkwürdigsten Reisen in Deutschland und Persien," published in 1782; "Leben Jesu, als Grundlage einer reinen Geschichte des Urchristenthums," 3 vols. 1788; "Aufklär. Beiträge zur Pogemen-Kirchen- und Religions-Geschichte," 1800; "Exegetisches Handbuch über die dreie ersten Evangelien," 3 vols., 1830 to 1833; ("Keizerichs" Geburts- und Lebens-Geschichte, zum Andenken an sein fünfzigjähriges Jubilrium, 1839; and the "Vorlesungen Schelling's über die Odenbarung," accompanied with critical remarks. Few men have had a wider influence upon religious opinions in Germany than Paulus; though many of his views have been contested as too rationalistic. In 1844 on account of his great age he was allowed to retire from his situation on a pension, and he died on August 9, 1850, aged ninety.

PAULUS, N. F.

PECULIAR. The jurisdiction of all Royal and other Peculars in the probate of Wills and the grant of Administrations has been transferred to the new Court of Probate. [Cit.]

PECIDELARIA, the name given by Müller to little pincher-rounded bodies found on the surface of many species of star-fishes and sea-urchins. When seen on the surface of the dried specimen they appear like little cleft spines. In Usaster rubens, according to Mr. Sharpey, they cover the surface generally, and are more numerous round the spines. Each one of these little bodies consists of a soft stem, which bears on its summit a little forceps of calcareous matter. If anything is introduced between the blades of these forceps which will act as an irritant, it is instantly converted into a powerful dextrorse forceps. Those on the body and upper spines differ in shape from those on the spines immediately bordering the auries. When the star-fish is living the blades of the forceps are in continual activity, but when cut off they seem to lose that power. These bodies have been observed by Sars in Echinus spharca, and he describes three species—P. tridens, P. trophylla, and P. globifera.

The question of the nature of these bodies has been often agitated. While some have considered them to be parasitic animals, Okon, Sharpey, and Sars regard them as organs of the animal. Sars assigns the following reasons for his belief:—

1. The calcaraceous forceps and stems to which they are attached, bear structurally a greater resemblance to the spines of Echinochordata than to other structures.

2. The Pedicellariae have a vital connection with the skin and shell of the Echinus. The stem of the Pedicellaria is attached to a knob of the shell of the Echinus, on which it moves.

3. The Pedicellariae have a vital connection with the skin and shell of the Echinus. The stem of the Pedicellaria is attached to a knob of the shell of the Echinus, on which it moves.

4. Sars states that when a single Pedicellaria is irritated, the rest are induced towards it.

Although Professor E. Forbes states that he was not able to confirm the Sars view, and that he used to imagine that the pedicellariae was not peculiar organs of Echinodermata, rather than parasitic animals.

(Forbes, British Our-Fish.)

PEDIANTHUS, a genus of Plants belonging to the natural order Euphorbiaceae. It has a common slipper-shaped involvulus. The male flowers several in the circumference. Pedicell bracteolate, each articulated with a naked stem. Female flowers one in the centre. Calyx wanting; style 1; stigma 3; capsules 3.

P. titylumeloides, Jew-Bush, is found in various parts of the West Indies in stony bushy places, near the coast. It is a shrub throwing out runners, erect, about six feet high, bearing, when young, a large white bloom, and numerous many-seeded, weak, soft, as thick as the finger; when old cinereous, when young green. The leaves are ovate, oblate, or acute; corollae, entire, alternate, stalked, dishaceous, when young downy on each side, and wavy at the edges, becoming at last cleft, entire, and discaceous; the ovary covered with papillates, scented with the extremities of the branches. Involucr slitem-shaped, bright red with a green back. The practitioners of Carapa give a decoction of the whole plant, especially of the stem, as the ordinary beverage, and in large doses in some diseases.

PEEL, SIR ROBERT, the second baronet of the name, was born on the 6th of February, 1778, near Bury in Lancashire, the eldest son and third child of the first Sir Robert Peel. He succeeded his father at the age of twenty-one to the House of Commons as member for Caen. His father had destined him for a political career, and from the time of his first entrance into Parliament he was placed in a position of absolute independency, and his father's position out of his income equal in amount to the fortune of many a nobleman.

On entering Parliament Mr. Peel attached himself to the Tory party, to which his father already belonged. Peel never had any great political ambition, and was content with the situation of his father, and with the most powerful coadjutors; while on the Whig benches sat Sheridan, Tierney, Whitbread, Horner, Brougham, Romilly, and Sir Frances Burdett. The elder Peel had made no secret of the great expectations he entertained of his son's success in Parliament; and in his young man's first steps in the walk of life for which he had been carefully trained, were looked at with much interest and with some jealousy. But Mr. Peel was prudent, and was in no haste to measure himself against the established orators of the House. His father having stepped down, Mr. Peel was seconded the address at the opening of the session. His subsequent votes and speeches gained him the reputation of a steady and able young man, from whom much might be expected; and, on quitting the university he took what was then (the modern examination system having been but recently introduced) the unprecedented honour of a double first-class—i.e. of paramount excellence both in classics and in mathematics. He had scarcely left college when, in 1800, at the age of twenty-one he was returned to the House of Commons as member for Caen. His father had destined him for a political career, and from the time of his first entrance into Parliament he was placed in a position of absolute independency, and his father's position out of his income equal in amount to the fortune of many a nobleman.

On entering Parliament Mr. Peel attached himself to the Tory party, to which his father already belonged. Peel never had any great political ambition, and was content with the situation of his father, and with the most powerful coadjutors; while on the Whig benches sat Sheridan, Tierney, Whitbread, Horner, Brougham, Romilly, and Sir Frances Burdett. The elder Peel had made no secret of the great expectations he entertained of his son's success in Parliament; and in his young man's first steps in the walk of life for which he had been carefully trained, were looked at with much interest and with some jealousy. But Mr. Peel was prudent, and was in no haste to measure himself against the established orators of the House. His father having stepped down, Mr. Peel was seconded the address at the opening of the session. His subsequent votes and speeches gained him the reputation of a steady and able young man, from whom much might be expected; and, on quitting the university he took what was then (the modern examination system having been but recently introduced) the unprecedented honour of a double first-class—i.e. of paramount excellence both in classics and in mathematics. He had scarcely left college when, in 1800, at the age of twenty-one he was returned to the House of Commons as member for Caen. His father had destined him for a political career, and from the time of his first entrance into Parliament he was placed in a position of absolute independency, and his father's position out of his income equal in amount to the fortune of many a nobleman.
The Earl of Liverpool became premier with Lord Castlemere as foreign secretary, Lord Sidmouth as home secretary, Lord Eldon as chancellor, and others of the seniors of the same party in other places of the cabinet; while among the ministers out of cabinet, Mr. GRATTAN, as speaker, the Duke of Richmond as lord-lieutenant of Ireland, and Mr. Peel as chief secretary for Ireland. The post accepted by Mr. Peel in this ministry, stationing him as it did in the midst of the tempestuous sea of Irish politics, was not new to him; among his predecessors in 1806, 1811, and with the union of 1800 had not yet subsided; the agitation for Catholic emancipation was fiercer than ever; and Mr. O'Connell had just become the leader of the Irish people, and was singling out objects against which to direct the full force of his oratory. The new ministry was identified with the anti-Catholic policy of the existing ministry; he was nick-named 'Orange-Peel;' and Mr. O'Connell seemed from the first to conceive an implacable hate to him personally. Various manifestations of this animosity, Mr. O'Connell in May, 1815, attacked him in one of his public speeches in terms so directly insulting that a challenge was the consequence. Some delay however having occurred in settling the preliminaries, the duel was prevented. Mr. Peel turned out to be a man of the blackest blackguardism by one party and to infidelity by the other; and by the diligence alone with which he sought to remedy the multifarious aches and total want of order which existed in the details of his own office, did he gain credit in Ireland with either party. In all else, for his party as well as for the empire, he was too much of a nonentity. He was too timid, and by the influence alone, to object to the reform of the church and the resignation of the secretaries having sufficed; and the people, the faction answered, their king, and the Catholic party, parce l'amour.

Meanwhile however he acted consistently with his position as Irish secretary under the Liverpool administration. Not only did he oppose Mr. Grattan's motion for a committee to consider the Roman Catholic claims in February, 1813, and again Sir Henry Parnell's motion on the same subject in 1815, but his speeches on both these occasions were the shrillest that he had yet delivered, and among the most telling on that side of the debate. The common charges against the decision of the practice of the House of Commons, having retired into the Upper House as Lord Colchester, and a vacancy having in consequence occurred in the representation of the University of Oxford, Mr. Peel was elected his successor (1818). Mr. Canning was inspired to the honour; but the influence of Lord Eldon, and the conviction entertained by the university of the orthodoxy of Mr. Peel's views on the Roman Catholic question, determined the choice. Mr. Peel then, greatly to the regret and astonishment of the more far-sighted of his party, strongly opposed the bill, and resigned his seat. It was during this period, too, that the leading part he took in the pressing currency questions of the day, he laid the foundation of his subsequent fame as a financier. He had already shown his sympathy with the views of what was then called the Catholic party, of which Mr. Horner during his life had been the head, and to which the House about this time received a powerful accession in Mr. David Ricardo; and on the appointment of a select committee in February 1819, to consider the question of the remuneration of the public officers, a payment was rendered necessary by the commercial distresses attending the transition from a state of war to one of peace, Mr. Peel, then only thirty-one years of age, was appointed chairman, having been a member of the committee of 1807, and of Sir John Robinson, Sir James Mackintosh.

In the proceedings of this committee and the debates which arose out of them, Mr. Peel displayed his ability both as a speaker and as a man of business; and it was in May 1819 that, with a future salary of £5,000 a year, and by cash-payments, he constituted himself the champion, to see his own words, of "the old, the vulgar doctrine, as some called it, that the true standard of value consisted in a definite quantity of gold bullion;" Every sound writer on the subject," he said, came to the same conclusion, that a certain weight of gold bullion, with an impression on it denoting it to be of that certain weight, and of a certain fineness, constituted the only true, intelligible, and adequate standard of value; and when, in the further effect by parliament, there were not wanting members who despaired of them; and among these was Mr. Peel's father, Sir Robert. Besides this currency question, the further history of which we need not trace, Mr. Peel in the same year took part in the Liverpool government in their opposition to the then revived agitation for Parliamentary Reform. He approved of the famous 'Six Acts;' and—what was long afterwards remembered by the other party to his discredit—was defended, with a vigour all the more remarkable, that he was not called upon to exhibit it by any official connexion with government, the conduct of the magistracy in the so-called 'Manchester massacre' of August 1819. He kept aloof however, with studious caution, from the ministerial proceedings of Queen Caroline, which followed the demise of George III. and the accession of George IV. to the throne (January 29, 1809), and which were terminated by the queen's death in August, 1811. It was in the midst of this storm of matrimonial politics that Mr. Peel himself married. His bride was Julia, the youngest daughter of General Sir John Floyd, Bart. The marriage took place on the 8th of June, 1830.

George IV. having retained the Liverpool ministry in office, Mr. Peel was induced again to become a member of it. In January, 1822, he took office as secretary of state for the home department. A further modification of the ministry was caused by the suicide, in August, of Lord Castlemere, whom Mr. Canning succeeded in the foreign secretariatship. The new foreign secretary was the first to turn the head of the government. It was he who took up this ministry, Mr. Canning and Mr. Peel continued to be the most prominent and active members of it—agreeing sufficiently to co-operate, but having at the same time the most certain different views. The position of the foreign policy of the country, Mr. Peel was busy with new forms of the currency-question peculiar to a time of unusual commercial distress and panic. While Mr. Canning was favourable to a consideration of the Roman Catholic claims, Mr. Peel, as before, opposed them, though with a growing conviction that the opposition could not be long continued. Both remained opposed to parliamentary reform. Prior to the time of Lord Liverpool's resignation his ministry was broken into two parties. Mr. TORY or EVEN-PEEL, was that which opposed the Roman Catholic claims, and of whom Mr. Peel was the active leader; and the liberal party, who, with Canning as their leader, were approximating to the Whigs. The question, on Lord Liverpool's retirement, was the state of the finance. The appointment of a nobleman of high rank and influence, such as the Duke of Wellington, to succeed him, the two parties could be held together, or whether a new ministry should be formed of which Canning should be the head. The second government was the answer. A new ministry was formed, though personally hostile to the Roman Catholic claims, empowered Mr. Canning to form a ministry in which the Roman Catholic question should be an open one, but which should pledge to the observance of the resolutions of the Tees and Corporation Act. In this ministry, the formation of which was regarded as a new epoch in the political history of the country, and was accordingly welcomed by many of the leading Whigs, Mr. Canning held the Chancel-
lorship of the Exchequer together with the premier's usual offices of Lord High Treasury and Lord Privy Seal, on the administration caused by the secession of Lord Eldon, Mr. Peel, the Duke of Wellington, Lord Melville, and others, were filled up by the selection of men willing to act along with Mr. Canning—among whom was Mr. Robinson (now called Sir Alexander); but on his resignation, in January 1828, a new ministry was formed of the old Tory construction, with the important and significant exception, that Lord Eldon was not re-instated in the position he had filled in it. The following was the composition of the cabinet of this memorable administration, which, from the names of its two chiefs, is now usually called the Wellington- Peel Administration:—First Lord of the Treasury, the Duke of Wellington; Chancellor of the Exchequer, Mr. Goulburn; Lord Chancellor, Lord Lyndhurst; President of the Council, Earl Bathurst; Lord Privy Seal, Lord Ellenborough; Foreign Secretary, Lord Dudley and Ward; Colonial Secretary, Mr. Huskisson; Home Secretary, Mr. Canning, then in the Mint, Mr. Herries; President of the India Board, Lord Minto; Board of Trade, Mr. Grant; Secretary at War, Lord Palmerston. The ministry was afterwards modified by the secession of Mr. Huskisson. Its great act was the passing of the Catholic Relief Bill—a great event, the necessity of which Mr. Peel had been prepared for; which was now pressed to an issue by the overwhelming influence of the Catholic Association in Ireland, as shown in the election of Mr. O'Connell to the House of Commons for the county of Clare, the result of which, it was announced on as soon as his election was known, had given his reluctant consent. On the 6th of March 1828, Mr. Peel—who had in the meantime been rejected by the University of Oxford in favour of Sir Harry Inglis, whose appointment to the same principle he sought forward the Relief Bill in the Commons, as member for the close borough of Westminster. His speech on this occasion was not only powerful at the time, but is interesting now as revealing what may be called the cardinal principle of Mr. Peel's career as a statesman. "We are placed," he said, "in a position in which we cannot remain. We cannot continue stationary. There is an evil in divided cabinets and distracted councils which cannot be longer tolerated. Supposing this to be established, and supposing it to be conceded that a united government must be formed in the nation, I say that government must choose one of two courses. They must advance or they must recede. They must grant further political privileges to the Roman Catholics, or they must make their demands by force. I have been, and now is, a new light has broken in upon me? Why do I see a necessity for concession now which was not evident before? The same events, I am told, have happened before, and therefore the same consequences ought to follow! Is this the fact? Are events in politics like equal quantities in numbers or mathematics, always the same? Are they, like the great abstract truths of morality, eternal and inviolable in their application? May not the recurrence—the continued recurrence of the very same event—nearly alter its character, at least its practical results?" Mr. Peel on this occasion spoke out, as a statesman, the general sense of the nation; and the Emancipation Act, after running the gauntlet of the Upper House, became law. Besides this great measure, Mr. Peel, as Home Secretary, introduced the New Metropolitan Police Act, which provided London with its efficient body of 'Peelers,' subject to the Home Office, in lieu of the old 'Charlies.' Questions of currency also occupied him during this administration. Though the Wellington-Peel government had yielded on the Roman Catholic Relief question, they were not prepared to yield on the great constitutional question of Parliamentary Reform. When, in February 1830, Lord John Russell moved the question of disfranchising the corrupt boroughs, and transferring the representation to some of the large commercial towns then unrepresented, Mr. Peel opposed the motion, "because it introduced a principle into the system of government that of numerical majority—which he said was the ultra-democratic principle, and at war with the aristocratic and monarchical principle could not long coexist." The death of George IV. however (June 26, 1830), and the accession of William IV., followed as it was by an immediate dissolution of Parliament and a general election (not to speak of the concurrent influence of the French Revolution of July), rendered the continued refusal of Parliamentary Reform impossible. After the re-assembling of Parliament on the 2nd of November 1830, the Duke again repe- }

...
and irreproachable settlement of a great constitutional question—a settlement which no friend to the peace and welfare of the country, or to the force of popular opinion, could view insidiously.

Proceeding on this as a fixed principle, the new ministry was to govern the country in a Conservative spirit, but with a readiness to carry into effect certain minor domestic reforms which were indicated. This point was met in the Reform Bill. The remnant of the old Tories, who were not satisfactorily to the country at large. The Reform Bill had not, indeed, produced all the results that the more eager had anticipated; the Whigs had not, as was generally expected, popular support, and the disappointment had begun to show itself among the Radical party, who criticised the Whigs severely and were bent on carrying further constitutional changes. Still, the re-action against Whig rule was not yet gained. Sir Robert Peel and his followers could stand its ground. This was shown by the result of the elections which followed the dissolution of Parliament—a dissolution thought necessary by Sir Robert himself. As soon as the new Parliament met, government was defeated by a majority of 618 to 306 on the election of a speaker—Mr. Abercorn, the nominee of the Whigs (now Lord Darnifold), being chosen instead of the former speaker, Sir Charles Sutton. This was on the 19th of February 1835; and on the 29th the Whigs were defeated in the Commons by a majority of seven, on a motion by Lord Morpeth for an amendment on the address. Sir Robert's speech on this occasion was extremely able. Singing out the fact that the strength of the opposition to him and his followers was not only increased by Irish members with the Whigs, he animadverted in cutting terms on this conjunction, seeing that in point of fact the Irish party and the Radicals had been far more unfriendly to the downfall of Whig ministry than he and his followers; and, seeing also that even now the Whigs did not pledge themselves, any more than he did, to the ballot, the exclusion of bishops from the House of Lords, the repeal of the Corn Laws, or any other of those measures upon which the Radicals had been so constant in their denunciations, the result was, that a Whig ministry could not really be a whit more innovative than his own would be. The answer to this given at the time, says Mr. Doubleday, was "that the Whigs would be more 'squeamish' than the Conservatives;" and, accordingly, though Sir Robert remained in office, showing wonderful patience and wonderful practical talent, till April, he was then defeated by so considerable a majority, in a skillfully framed series of motions of Lord John Russell's, relative to the temporariness of the Conjectural Bill, which he had not introduced till April 6th, 1835. Lord Russell was again placed at the head of a Whig administration, consisting of nearly the same men who had been in office four months before, the chief exception being that in the intermediate period Sir Robert Peel had resigned the Whigs and Lord Brougham, so that the chancellory was given not to him but to Lord Cottenham. Lord John Russell became home secretary.

The second Melbourne administration lasted throughout the rest of the reign of William IV. (who died June 20, 1837) and during nearly four years of the reign of Queen Victoria. During those six years (1835-1841) though many questions were agitated, their chief success was in the Municipal Reform Bill, passed during the first year. From 1836 to 1839 they were able to do little, and, robbed of their strength as they were by the growth of the more extreme party and of the party who desired a repeal of the Corn Laws, they were becoming more and more unpopular. At last Sir Robert Peel, whose popularity had been in proportion increasing, and who had in the meantime been acting as a critic of their measures, and husbanding his own strength, opposed their bill for suspending the constitution of the Colony of Jamaica; and the majority of the opposition was at once against it. Sir Robert was called upon to form a new ministry. In this he failed, owing to the refusal of the queen to consent to the removal of the office of Lord Chancellor from the hands of the Whigs. Sir Robert Peel was inconsistent with their holding official place under a Conservative government. The Whigs accordingly resumed office, and kept it for more than two years longer—weakened, as before, by the pressure upon them of Mr. O'Connell's party, and the Anti-Corn Law League on the one hand, and of Sir Robert Peel and his well-drilled Conservatives on the other. A general election in 1841, instead of giving them fresh strength, so increased the Unionists who were their bitterest foes that Sir Robert Peel had a majority of 360 against 269 in the Commons on a motion for an amendment to the address so framed as to involve a vote of want of confidence in the policy of ministers, more especially their policy on the Corn Laws. This minute reference to the Corn Laws (Aug. 27, 1841). Three days afterwards Lord Melbourne and his colleagues resigned, and Sir Robert Peel was once more premier. The new Conservative cabinet consisted of the following ministers:—First Lord of the Treasury, Sir Robert Peel; Lord Chancellor, Lord Lyndhurst; President of the Council, Lord Wharncliffe; First Lord of the Admiralty, Lord Haddington; Lord Privy Seal, the Duke of Buckingham; Home Secretary, Sir James Graham; Secretary of State for War, Sir John Russell; Secretary for the Colonies, Sir George Pakington; Colonial Secretary, Lord Stanley; President of the India Board, Lord Ellenborough; Secretary at War, Sir Henry Harden; President of the Board of Trade, Sir Thomas Gascoyne; Chancellor of the Exchequer, Mr. Goulburn; Paymaster-General, Sir Edward Anstis. Among the ministers not in the cabinet, was Mr. W. E. Gladstone, as Vice-President of the Board of Trade. At the head of this ministry, and with the command of a working majority of 265 out of a house of 652, Sir Robert Peel entered on the greatest period of his political career. The history of his ministry from August 1841 to July 1846 is full of interest. Having committed himself to no definite line of policy, except in his preference for a sliding-scale tariff, he was accepted by the country, on his accession to office, was left to form its own auguries and anticipations. Nor during the remainder of the session of 1841 would he bring forward any explicit statement of intended measures—resolved, he was to mature them during the prorogation. On the re-assembling of parliament in February 1842, he was prepared with his measures. They were of a bold and comprehensive character. First, in the matter of the Corn Laws, he proposed to repeal the duties, according to which the duty on foreign corn, commencing in the case of wheat at 20s. per quarter when wheat was at 50s., should gradually diminish, as the price rose,—becoming, for example, 17s., when wheat was at 55s., 11s., when wheat was at 60s., 8s., when wheat was at 70s., and only 1s. when wheat should be at 72s. or upwards. There was a corresponding scale for oats and another for barley. The measure, displacing as it did the old duties, was on various grounds attacked; and, because they had declared for a fixed duty, to the Anti-Corn Law League, because they desired a total repeal, and to many of the landed proprietors, because they disliked any relaxation of protection—croused much discussion; but after a severe moral, it was defeated, and, as the measure was rejected, it became law. Next came the important question of the means of repairing the deficit which had been going on in the revenue, at such a rate that the total for the five years ending April 5, 1842, was 7,529,635l., while in the year 1842-43, it was calculated by anticipation at 2,670,000. On this head, says Mr. Doubleday, Sir Robert argued "that the maximum of indirect taxation was then reached, and that to accumulate the already unbearable load of duties upon the necessary or even the luxuries of life would be ruinous as well as futile. The conclusion, therefore, was that nothing but a direct tax upon income could be relied upon to fill up the hiatus in the exchequer." Accordingly it was proposed to levy for three years an income-tax of sevenpence in the pound payable by men over 25. This also, in spite of opposition, was carried. Then came the reversion of the tariff, by which the premier abandoned the duties on a great variety of minor foreign commodities, such as drugs and dyes and dyewoods; and diminished the prohibitory duties on cattle, sheep, pigs, salted meat, butter, eggs, cheese, and lard. Though the new tariff was also carried, it caused dissension between Sir Robert and many of his Protectionist supporters; the more so, in the course of the debates a new principle was put forward, that the rule of the cheapest market and sell in the dearest." This statement drew rapturous cheers from the economists and
opposition generally; and though Sir Robert went on to say, that he deemed corn and sugar exceptional cases, the anterior tendency was evident. With the exception of some debates on the poor-law, and some on foreign policy in reference to France, Spain, America, and China, the foregoing measures of legislation and finance engrossed the parliament of 1842. The most important events of 1843 were extra-parliamentary. The permission of the disruption of the Scotch established Church in May 1843 has been accounted by some a moderate step towards greater religious conformity with the principles of conservatism, and has been attributed to false or insufficient information on the part of government. The contest with Mr. O'Connell, who was then agitating Ireland to the verge of revolution by monster-meetings and the organisation of the United Irishmen, was peculiarly of a kind to occupy a greater share of the energies of the government. For a time Sir Robert, confident, as it afterwards appeared, that Mr. O'Connell himself did not mean to be a candidate for a certain length, allowed him to proceed without check; but at length (October 1844) the government took their measures, the Clontarf meeting was forbidden, and Mr. O'Connell, his son John, and seven of their associates, were arrested on charges of conspiracy and sedition, and, being tried, were sentenced to fine and imprisonment. From that moment, although the sentence was reversed on appeal to the House of Lords, Mr. O'Connell was virtually crushed; he was never able again to be what he had been.

The year 1844, with its Bank Holiday, the Chartist riots, and the Marat affair, had passed away; and 1845 opened with every outward show of prosperity. The parliamentary session of that year was comparatively easy; the renewal of the income-tax for three years longer, the assessment of the boroughs, for the purpose of facilitating the presentation of six new Irish colleges, open to all sects, were carried by government; and though the Anti-Corn-Law League, represented in the House by Messrs. Cobden and Bright, were making way, and were gaining over the Whigs, the stability of the existing administration was not materially affected. But the events of the long recess of 1845 were of a kind to disturb all existing arrangements and all ordinary calculations. The potato rot, followed as it was by a dreadful famine in Ireland, rendered it impossible for the government to come to some conclusion on the great question which the Anti-Corn-Law League had been maturing. Lord John Russell announced this in his famous letter of the 22nd of November, written from Edinburgh, to the electors of London.

Sir Robert Peel lost no time in declaring to his colleagues that the Corn Laws must be totally repealed. In this Lord Stanley and others would not go along with him; and on the 6th of December, Sir Robert advised the queen to send for Lord John Russell. As Earl Grey refused to join with Lord Stanley, Lord Stanley resigned, and Sir Robert was recalled after a few days, and re-accepted office at the head of his ministry (Lord Stanley succeeding) with the avowed intention of repealing the Corn Laws. Accordingly, a corn law commission of parliament was appointed, he brought out a new tariff, and with it his proposition to modify the action of the sliding-scale for the next three years, and after that period to abolish all duties on corn, except the nominal one of a shilling per quarter. Vehement debates followed, in which Lord Stanley, Lord George Bentinck, and Mr. Disraeli, as the heads of a new Protectionist party, attacked Sir Robert with every weapon of sarcasm and argument. The Duke of Wellington however, and other Conservatives of great weight, remained firm to their leaders; and the repeal was carried. Defeated on the Irish Coercion Bill, only a few hours after the Tariff Bill had passed the Lords, Sir Robert resigned office (June 30, 1846). Before doing so he made a magnanimous declaration to the effect that the merit of the repeal of the Corn Laws was more to Mr. Cobden than to himself, or to any other man in the House. Never perhaps was a minister followed into his retirement with such general assurances as followed Sir Robert Peel. His popularity continued unabated during the next four years. During two of these he lent a general and cordial support to the Whig government of Lord John Russell—voting with them on the question of the Navigation Laws, and the most important of all, the Reform Bill. The European revolutionary movements of 1848-49 however, brought in a new set of questions, and Sir Robert disagreed seriously with the foreign policy of Lord Palmerston. Anticipations were general of his speedy return to power when, riding up Constitution-bill on the 29th of June 1850 he was thrown from his horse, and injured so severely that he died on the 2nd of July.

This is not the place for any attempt to appreciate Sir Robert's character as a man and a statesman. Many reviews of his career, some in the form of elaborate biographies, have been published since his death—among which may be mentioned 'The Political Life of Sir Robert Peel, by Thomas Doubleday, 2 vols., 1856; and M. Guizot's more recent work 'Life of Sir Robert Peel, a biographie historique,' published 1861, 2 vols., which contains many valuable and interesting letters and papers, referring particularly to his conduct in the Roman Catholic Emancipation movement, and in the Corn Law Repeal movement, have also been published by his literary executor. Almost all who have written about him have been disposed to view him as a moderate statesman, of sounder. conscience, and of a species of ability peculiarly English and peculiarly fitting him for the work which fell to him—ability not of the speculative or philosophical, but of the practical, deliberate, and considerate order. His political genius consisted in perceiving when the necessity for carrying a great social change arose, and in devising the parliamentary means for carrying it. As the leader of a party, and as a master of the art of parliamentary management, he was probably unrivalled; the House of Commons was his element; and though there have been greater orators there, there have been few speakers combining such dignity, tact and courtesy, with fine powers of eloquence. Apart from his parliamentary work, he extended his pleasures by certain of a pecuniary nature, partly by himself, who did not himself practise authorship except in connection with practical politics, were high and scholarly, and more wide in their range than might have been supposed.

Sir Robert left five sons—the present baronet, Sir Robert (born May 4, 1825); former Lord Mayor of London (1860); two daughters, one married (1841) Viscount Villiers, eldest son of Earl Jersey; the other married (1855) the Honourable Mr. Stonor.

PEERS OF THE REALM. In the case of Lord Wensleydale, to whom a barony had been granted for the term of seven years and not subject to entail, his successor was appointed a peer of the realm, by a refusal on his part to accept such a grant did not constitute the grantee a lord of Parliament; in other words, that hereditary peerage alone entitled the holders to a seat in the House of Lords.

PELLICULAE [Minoisolae, S. 1.] PELARGONIC ACID. [Chemistry, S. 2.] PELLICO, SILVIO, was born in 1759, at Saluzzo, in Piedmont. His father was Onorato Pellico, of a respectable family, and in good circumstances. His mother was a native of Chambery in Savoy, who, retaining her native name in marriage, married Michael Le Pellico-Tournier, who was the son of Luigi and Gio- sefina, the two eldest; Silvio and Rosina, twins, followed; Francesco and Margherita were next in succession. Two daughters married, one of which was married to her husband's brother, and the other to her husband's brother's son. Onorato Pellico, while his children were yet young, having established a manufacture for winding silk at Pinerolo, resided there some time; but removed to Turin, where he was appointed to a situation under the govern-
ment. There Luigi and Silvio were instructed in Latin and Greek, and other branches of education, by Don Manavella, a clergyman. Onorato Pellico, who had a taste for poetry and the drama, wrote scenes and short plays, which were performed by his children and others of a similar age, on a small stage constructed in his father's house. Luigi afterwards became a dramatist, as well as Silvio.

Silvio Pellico's twin-sister Rosina, who is described as having been extremely beautiful, was married at the age of eighteen to a cousin by the mother's side, who was prosperous, and they had five children. Silvio Pellico-Tournois, with his sister Silvia, accompanied the bride to the residence of her husband. The mother after a short stay returned home, but Silvio continued to reside with his sister's husband during four years. While on tour in 1807 Ugo Foscolo, who was the Meinheimer of Silvio Pellico's contract ("La Ermodice") was published, and was sent to him by his brother Luigi. The reading of it excited him greatly, and stimulated him to the prosecution of his poetical studies. Meantime his father had changed his situation under the minister of Milan, and had removed to that city with his family. His brother Luigi was secretary to the Marquis Caprara, grand equerry of the kingdom of Italy.

Silvio Pellico returned from France in 1810, and went to Milan to enter the Collegio degli Orfani Militari, an institution which required two or three hours of the day. The rest of his time was devoted to his poetical studies and to the acquisition of the German and English languages. He became acquainted with Ugo Foscolo, who resided in the same city, and of whose most important work of Italy and with many distinguished foreigners, among whom he himself mentions Madame de Staël, Schlegel, Davy, Byron, Hobhouse, and Brougham. After the fall of Napoleon I, Onorato Pellico returned to his native land, and with the most lucrative offer of France, and having been converted to the Catholic faith, he became a tutor. In 1818 Silvio Pellico published his first dramatic piece, the tragedy of "Laodamia," which was followed by his tragedy of "Francesco, da Rimini," founded on a well-known passage in the 5th canto of the "Inferno" of Dante. This tragedy was much admired, acted with great applause in the principal cities of Italy, and established his reputation as a dramatic poet. Byron translated it into English verse, but did not publish it, and Pellico translated Byron's "Manfred" into Italian prose. He was desirous of publishing his next tragedy, "Esemio da Messina;" but so many passages were objected to by the censorship that he sent it to Turin, where it was more favourably received, and published at Milan, but was not allowed to be acted. In 1818 Silvio Pellico was the chief agent in establishing a periodical entitled "Il Conciliatore," of which he became the secretary. It was mainly of a literary character, and Silvio Pellico, Manzoni, and similar literary men, were the chief contributors; but it was of too liberal a tendency to be endured by the Austrian government, and was suppressed.

On the 13th of October 1850 Silvio Pellico was arrested, and was confined in the prison of Santa Margherita at Milan. He seems to have become a member of the revolutionist society called Carbonari, but does not say so. He was transferred thence to a prison on the island of San Michele, near Venice; and while there was tried at Venice, found guilty, and condemned to have his ear removed. He was permitted to remain in prison until after the expiration of the first term, and was then allowed to go to Turin, but was not allowed to be acted. In 1822 he was removed to the prison of Spielberg, near the city of Brünn, in Moravia. Some of those sent to this prison are condemned to the "carraro duro" (severe imprisonment), and some to the "carraro dolce." In 1830 and occasionally for Silvio Pellico says—"Those condemned to the "carraro duro" are obliged to labour, to wear chains on their feet, to sleep on bare boards, and to eat the poorest food. Those condemned to the "carraro dolce" are allowed to walk without chains with a hand of iron round the waist, the chain being fastened in the wall, so that they can walk only just by the side of the boards which serve them for a bed. Their food is the same, though the law says only bread and water." In the next few months, he was treated with indulgence by his jailer, and read the Bible, Homer in Greek, Dante, Petrarch, Shakspere, Byron, Scott, Schiller, Gütte, and other writers, and was allowed some paper, and pen and ink. His friendly jails having been removed to another situation, during the whole of the years 1824-25-26-27 his imprisonment was excessively severe, and his health was much injured. His imprisonment towards the less stringent, and on the 1st of August 1830 he received the permission to return home in the capacity of a "carraro dolce." This promise was soon afterwards performed, and he returned to his parents at Turin. In 1831 he published the account of his imprisonments, entitled "Le Mie Frigiones," which has been translated into English, and again into Italian, and translated into the principal languages of Europe. It is written in a style of great simplicity, with much apparent truthfulness, and is very interesting. In 1832 he published at Turin "Tre Novelle Tragedie," which were "Gismonda da Mandriva," "L'oppio & Erodiade," and "Tommaso Moro." His mother died in 1837, his father in 1838, and his brother Luigi in 1841. In 1837 he published the "Opere Inedite," 2 vols. One of his latest works was a treatise in prose, "Dei Doveri degli Uomini," "On the Duties of Men." During his later years Silvio Pellico was secretary to the Marchesa Barola, and he died at her villa of Moncalieri, near Turin, January 1, 1854.

PEN, a small natural order of Perigynous Exogenous Insects. The males are large, with imbricated ex stipulated leaves. The flowers are apetalous, the ovary composed of four carpels, the calyx tubular. Lindley places this order in his Rhamnaceae, and points out its relations with Proteaceae and Dracaceae. The species are mostly natives of the Cape of Good Hope. A violaceous sweetish nauseous gum-resin, called Sarcocoll, is produced by various species. This substance contains a peculiar principle called Sarcoceollin, which is converted into oxalic acid by the action of water. Although Dr. Lindley has named this plant Sarcocolla, it has also been called Endlicheria, if this order really produces Sarcocoll at all; and suggests that it is produced, as Sagapenum and Galanhum, by a species of the order Umbellifere. The genera are Ficus, Sarcocolla, and Genus. There are 21 species.

PENOFIS. [Yorkehill.]

PENNINE, a small natural order of Perigynous Exogenous Insects. The males are large, with imbricated ex stipulated leaves. The flowers are apetalous, the ovary composed of four carpels, the calyx tubular. Lindley places this order in his Rhamnaceae, and points out its relations with Proteaceae and Dracaceae. The species are mostly natives of the Cape of Good Hope. A violaceous sweetish nauseous gum-resin, called Sarcocoll, is produced by various species. This substance contains a peculiar principle called Sarcoceollin, which is converted into oxalic acid by the action of water. Although Dr. Lindley has named this plant Sarcocolla, it has also been called Endlicheria, if this order really produces Sarcocoll at all; and suggests that it is produced, as Sagapenum and Galanhum, by a species of the order Umbellifere. The genera are Ficus, Sarcocolla, and Genus. There are 21 species.

Pellicina (Forbes) has an irregular oval body, arcaned with five rows of distant suckers, those below being always bent; tentacula ten; dental apparatus short, truncate; no gizzard.

P. brevis, of Forbes and Goodrich, is the only species. It was discovered in the Shetland seas, adhering to the stems of Lamarnia, a small water plant. "Tentaculata. It is about half an inch in length, of an oval form, with both its extremities bent upwards. The body is pinkish-white, with minute papillae. The tentacula are long, pedicled, and digitate at the extremity. It is sluggish in its movements, but its tentaculata freely.

Cucumaria has the body regular, more or less pentangular, with five longitudinal rows of approximate suckers; ten tentacula; dental apparatus composed of nearly square plates.

The species are called Sea-Cucumbers. They are the most typical of the Holothuriidae, and their popular name is very expressive of their usual form. They have all of them the power of changing their shape, so that sometimes they are large and oval, at other times they are very long, and sometimes they are round. They usually live, among sea-weeds or in mud, and are supposed to seize their prey by their large tentacula. They are found very generally throughout the seas of the globe. The following are the British species described by Professor E. Forbes in his "History of the Cucumaria." -

C. frondosa (Holothuria frondosa, Gunner), the Great Sea-Cucumber. It has been principally found off the coasts of Scotland.

C. pentactes (Holothuria pentactes, Müller), the Angular Sea-Cucumber. It has been taken on the coasts of Devonshire and Dorsetshire, and is found in the seas of France and Norway.

C. communis, Common Sea-Cucumber. Great numbers of these animals have been observed off the coast of Fife, and being dredged in the north and south of Ireland, by Mr. W. Thompson and Dr. Ball.

3 5
serve its digestive power for ever, unless the fluid became saturated with the dissolved substances, or the conjugated acid underwent decomposition.

(Lehmann, *Physiological Chemistry*, translated for the Cavendish Society.)

PEPYS, WILLIAM HASELDINE, F.R.S., was born in the year 1775, in the city of London, where his father conducted in the Poultry a superior business as a butcher and maker of certain classes of surgical instruments. His early history is a remarkable illustration of the progress of chemistry, and of some other branches of science in this country, as well as with that of the various institutions formed for their advancement. In March 1796 the Askeansea Society (from here, exercise, was established and Mr. Pepys was immediately appointed by the body of managers for the purpose of bringing about any improvement by the discussion of philosophical subjects. Of these Mr. Pepys was one. He became a member of the Committee for Apparatus appointed by the society, and took an active part in the experimental elucidation to the members of facts generally understood, and in the repetition and examination of new discoveries. Mr. Pepys also contributed papers to the same body, which, from the residence or occupation of its members in the city of London, eventually led to the foundation of the London Institution, and, through the British Mineralogical Society, in part also to the establishment of the Geological Society of London, of which Mr. Pepys was an early member and office-bearer. His skill and ingenuity in the construction of apparatus proved most important in the development of chemical and physical sciences in England for a period exceeding thirty years. His researches on respiration, prosecuted in conjunction with Mr. Allen [Allen, William, S. 1], and published in the Transactions of the Royal Society, have established the foundation of our exact knowledge of the chemical changes produced in air by that process; while their preliminary experiments on carbon and carbonic acid, recorded in papers contained in the same collection, confirmed several points in the chemical history of those bodies, which had remained in doubt or been insufficiently examined. In 1808 Mr. Pepys was elected a Fellow of the Royal Society, in the proceedings of which he took an active part for many years.

As just intimated, he was one of the earliest promoters of the London Institution for the Advancement of Literature and the Diffusion of Useful Knowledge, which was founded in 1808 and 1806, with the intention of supplying for the City of London, advantageously combined with those of the metropolis from the establishment of the Royal Institution, a few years before. He is named as one of the managers of the London Institution in the Charter of Incorporation, dated January 21st, 1807, and for many years he continued to be, an officer of the Board, the arrangements for the laboratory, the collection of chemical and philosophical apparatus, and subsequently for the lectures, were mainly carried out by him, and from 1821 to 1834 he was honorary secretary. After an interval of some years he was re-elected a member of the Board, and as president, which office he continued to hold during the remainder of his life. Under his direction a voltaic battery of 2000 double plates of zinc and copper was constructed for the laboratory, with which many of Sir Humphry Davy's experiments on the magnetic phenomena produced by electricity were made, with the personal assistance of Mr. Pepys and other friends. In the 'Philosophical Transactions' for 1825 is described another voltaic battery devised by Mr. Pepys. Mr. Pepys was also a student in electro-magnetic experiments, and constructed for the London Institution, consisting of two plates only, one of copper, the other of zinc, and those each fifty feet in length and two in width, coiled around each other. A remarkable experiment repeated by Sir H. Davy and others in the laboratory, this apparatus was often used to electrify the contemporaries of Davy and Wollaston. He died at his house in Earl's Terrace, Kensington, London, on the 17th of August 1856, at the age of eighty-one.
PERCH. [Perci.] Fish.

PERCUOIDEI. [Percidae].

PERRORAS, an eminent physician and pharmacologist, was born in the parish of Shoreditch, London, on the 22nd of May 1804. He received his early education in his native parish, and was distinguished at school for his knowledge of classics. At the age of fourteen he was apprenticed to Mr. Latham of the City-road, a physician who practised as a surgeon and apothecary. His master having died, he commenced attending on the practice of the Aldersgate-street Dispensary in 1821. At this time his dispensary was recognised by the Apothecaries' Society as one of the institutions to which medical students were admitted to qualify for medical degrees. In 1823 he obtained his licence to fit him for this purpose, and was admitted as a candidate for the Apothecaries' licence. The physicians and surgeons of the dispensary gave lectures, which were also recognised by the Society of Apothecaries. In 1832 he was appointed Surgeon to St. Bartholomew's Hospital, and in March 1832 obtained his licence to practise from the examiners of the Society of Apothecaries. He was not nineteen years old, and the facility with which he obtained his licence, indicates very plainly how small an amount of education was required for the medical man at this time. He was shortly after appointed apothecary to the Aldersgate-street Dispensary, and thenceforward his name was connected with the falling fortunes of this at one time somewhat celebrated school of medicine.

On leaving the dispensary he once established himself as a private tutor or 'grinder' as teachers of this class are technically called. In this capacity he was very efficient, and his early publications all had reference to the wants of medical students. He was at this time still a young man, and his work was at once popular and useful. He published an English translation of the Latin Pharmacopoeia of the London College of Physicians. He also published a collection of Latin precepts, entitled "Selecta et Prescripta," a large number of which have been printed. He devoted much time to chemistry and published "A General Table of Atomic Numbers." In 1825 he became a member of the Royal College of Surgeons. In 1836 he was appointed lecturer in chemistry in the Aldersgate-street school of medicine, and subsequently delivered the course in the college on materia medica. The lectures were the foundation of his great work on Materia Medica and his reputation as a pharmacologist. The lectures were first published in the Medical Gazette, and the matter was subsequently re-arranged and published in two volumes in 1839, under the title "Elements of Materia Medica and Therapeutics." Dr. Pereira's mind was eminently discursive. Even while lecturing on Chemistry and Materia Medica in Aldersgate-street he undertook to lecture on chemistry and botany at the London University, and was successful in this, confiding his lectures largely in writing. He was finally appointed Lecturer on Chemistry and Materia Medica, and his work a produce more scientific and practical than any which had before been devoted to the prolific subject of medicines and their actions.

Up to this time he had practised as a general practitioner; but in 1840 he was appointed Lecturer on Materia Medica, prepared the way for his appointment as physician to that institution. He accordingly in 1840 obtained the degree of doctor of medicine from the University of Erlangen, and was appointed in the same year assistant physician to the London Hospital. He subsequently submitted to the examination of the College of Physicians, and became a London licentiate of that body. He was selected a fellow of the College in 1845. In connection with Materia Medica, Dr. Pereira devoted himself to the Materia Dietetica, and in 1842 he published a treatise on "Food and Diet," which, like his work on Materia Medica, was by far the best that had been published on that subject.

His works brought Dr. Pereira into considerable note as a physician, and the firmness of his practice compelled him to give up his various lectureships. In 1861 he was appointed full physician to the London Hospital. His great knowledge of Materia Medica pointed him out as the most fitting person to fill the next vacant chair at the London University, an office which he held till his death.

Although Dr. Pereira occupied himself more with compiling and arranging the information obtained from others than with original observations, he nevertheless displayed considerable originality, and, as his admirers say, his practice was founded on a sound knowledge of materia medica. He published a series of "Lectures on Polariised Light," and many original papers and observations in the Pharmaceutical and Medical Journals. He took an interest in the formation of the Pharmaceutical Society, and delivered several courses of lectures on Materia Medica in connection with that Society. He was a fellow of the Royal Society and also of the Linnean Society. His death, which occurred in 1853, was sudden, but he had been acquainted with this event to his former teacher, Professor Quennell (of the College of Surgeons, London) on a scientific question, and whilst declining a staircase leading to the Hunterian Museum, made a false step, fell, and ruptured the rectus femoris muscle of both legs. In all probability at the same time some internal injury was sustained by the heart or larger vessels; but as only local inconvenience was experienced, no danger was apprehended; but whilst getting into bed on the 30th of January he felt a violent throb in the region of the heart, and immediately gave notice that a speedy termination of his life was at hand, and this impression was verified within twenty minutes after. A bust was erected to his memory in the London Hospital by his friends.

PERIANS, a n. [Periandria].

PERICLASE, a Mineral, occurring crystallised in regular octahedrons. Primary form a cube. Cleavage in three directions parallel to the face of the cube. Colour obscure green. Hardness equal to felspar. Vitreous translucent. Specific gravity 3.97. It is found in the lava of Vesuvius. Its analysis by Damour gives —

PERISTEATION, a genus of Fishes belonging to the Acoutheretopori. With hard body. The body is covered with bony plates, forming a defensive armature. The nasal bone is the P. Malarost, the Mailed Gurnard, was taken, according to Mr. Yarrell, off Plymouth in 1836. It is also a native of the Mediterranean. It is easily known from the other gurnards by its elongated and bifurcated nasal bones. It frequents deep water over rocky grounds, and is generally allowed only at the period of spawning. It swims with great rapidity, occasionally breaking its nose against the rocks. It is fished in the Mediterranean, and as an article of food is in greatest estimation. (Leach.)

PERIWINKLE, a Plant. [Vinca].

PERJURY. A summary power of committing persons guilty of perjury is vested in all the courts of the county by the statute 14 and 15 Vict., c. 100. One object of the statute is to give the prosecutor his costs, when the prosecution is directed by the court. It was passed to meet an expected increase of crimes of this nature, from the parties being allowed to give evidence in their own causes.

PEROVSKITES. [Minerall].

PERKET, S. L. [Perkins].

PERTHES, CHRISTOPHER FRIEDRICH, one of the most distinguished booksellers of Germany, was born April 21, 1773, at Rudolstadt, the capital of the petty German principality of Schwarzburg, whose father was secretary of state in the exchancellorship of the same principality. In 1777, when a boy of fourteen, he was transferred to his maternal uncle, Friedrich Hebel, also a state official of the Prince of Schwarzburg, who, as far as he was able instructed the young Perthes, instilled good principles into him, but little of literature. At the age of twelve he was sent to the gymnasiurn of Rudolstadt, but his previous deficiencies rendered him unable to profit much by the instruction here afforded, a loss which he continued to lament in later life, and which then made great efforts to overcome. At this period he showed great delight in reading and music, and they appear to have had much influence in developing a feeling of self-dependence on his own exertions; and another relation, Lieutenant-Colonel Hebel, the superintendent of public buildings, by taking young Perthes under his protection, gave him a liking for natural scenery. A brother of his father's was a bookseller at Gotha, and this seems to have led to the idea of dedicating Perthes to that trade. In 1786, therefore, he was taken to the great book-selling mart at Leipzig, as a statute apprentice for him. He was, however, dismissed by one because he could not construe one, and by another as too delicate; but one, Böhme, agreed to accept him as an apprentice at the end of another year. On September 11, 1757, he entered upon his new occupation. His master was not kind, but strict; he was employed in the lower and more...
irkson duties of his trade: particularly as a collector; his feet were frost-bitten in the winter; he was confined to his room for nine weeks, during which his master's daughter, Frederika, then only fourteen years old, said, he read to her a translation of Muratori's "History of Italy." He recovered and became fondly attached to his nurse. While serving his apprenticeship his desire for acquiring knowledge was great, but his means were so restricted that he determined to make some temporary exertions. His mother's pension (about 2½ a year), a few occasional presents from his uncle Henbel, and two dollars yearly from his master, formed the extent of his funds, and with these he had to supply himself with shoes and clothes. After he had completed some of the common apprenticeship, James Nissig, was introduced. This associate became a candidate for the affections of Frederika. The rivalry revealed to Perthes that he was in love, and like a true German, he made a confidant of his rival. They agreed to make each attempt to gain her, and that the unsuccessful suitor was to be uncomplainingly to his fate. In 1792, when the French revolution broke out, both uncle and nephew took a great interest in its progress; but Perthes saw and expressed in his letters to his uncle reasons for apprehending danger. His manners appear to have been all his life peculiarly attractive, modest yet firm; and while with Böhme he became acquainted with Göthe, Herder, and Schiller. At the Easter fair of 1793, Hoffmann, a large publisher in Hamburg, having received a letter from his sister, had written to the master released him from his apprenticeship, which had yet a year to run, and he departed with Hoffmann to Hamburg. While here, though sedulously attended to his business, he led a life of his own attachment, and corresponded with his rival, Nissig, who undertook to be a great patron of Frederika, and the state of her affections. His notions of bookselling appear to have far exceeded those of either of his masters. In 1794 he writes: "Where will you find a body of men more deficient in the requisites of information, and so negligent of the duties of their calling, as the booksellers? Germany is deluged with wretched and abominable publications, and will be delivered from this plague only when the world is made rare for honour than for gold." After a residence of about three years with Hoffmann during which he had won the esteem of many eminent literary men, and made great efforts to repair his defective education by study and by intercourse with the numerous French emigrants then in Hamburg, and having received a promise of the reversion of his uncle's business in Gotha, for which he was not inclined to wait, he determined to begin business for himself. This he effected on borrowed capital, and in partnership with his old fellow-apprentice, Nissig. As they were both young and inexperienced they were governed by Frederika Böhme, who declined to marry either, though she owned that she loved both—a good reason, perhaps, for her resolution. Perthes was in despair. He writes, "my whole life was a failure. But he immersed himself in business, in hopes of thus overcoming the defect in his condition, and he succeeded. The partnership with Nissig did not last long, as it was found that, though not unsuccessful, the profits were not enough for two; and he now proceeded on his own account. His acquaintance with literary men extended. Fred. H. Jacob, the Stolberg's, Voss, and Count Reventlow were among them. By Jacob he was introduced to Claudine, the editor of the 'Wandebcker Bote' (Mes- senschrift). When Caroline he married, after a short courtship, on August 2nd of that year. It was a delicate, a retiring woman, possessed of strong religious feelings, and an ardent love for her husband; but his active bustling habits gave her occasional uneasiness, and she would have preferred his being more calm and less worldly. To her gentle remonstrances he replied, "I am persuaded that I am, and must turn to my own wheel, and that of others, with energy." In 1793, with an addition of capital, also borrowed, he entered into the partnership with J. C. Becker, who, from his integrity, activity, and great literary knowledge, was soon considered the most popular bookseller in the business. This went on happily and successfully till 1803, when the French occupied Hanover, placed Hamburg in a state of blockade, and in 1806 occupied the town itself; and the business was released by the peace of Tilsit; it was incorporated in 1810 with the Frankfurt firm; the latter went on, though embarrassed by the Milan and Berlin decrees, and the censorship to which the press was subjected. Perthes had, in his correspondence, lamented the apathy of Germany under the French yoke, and when the French
During the periodical years, there appeared Pestalozzi's works, which had become famous in Austria, especially in Pestalozzi's native Bern, where he was born. Pestalozzi was a poet, and his works, entitled "The Educational Regimental Duties and Labourious Aspirations," became famous both in Bavaria and in his native country. He was a distinguished poet, and his works were considered a great contribution to the field of education.

Despite his physical and mental struggles, Pestalozzi continued his work, and his legacy lived on even after his death. His work was continued by his son, Janos, who took over the responsibilities of his father and continued the work of education.

In the same time, Petofi's Famous Gang was fought for the return of his native country, and on February 20, 1848, his body was found in the grass. The meaning of Petofi's name had changed, and the memory of the young poet, who was also a great fighter, was preserved.

The Slavonic and Exogenous words were associated with the period, and their meanings were changed. The words "Slavonic" and "Exogenous" were used to describe the relationship of the Slavic countries with the rest of the world. The word "Exogenous" was used to describe the relationship of the Slavic countries with the rest of the world. The word "Slavonic" was used to describe the language and culture of the Slavic countries.

for hostility to the absolutism, as well as by a warm feeling of national independence.

On the 16th of March, it was Petöfi who incited the students of the university to action by reading aloud in the yard of the university his poem of 'Talpja Magyar' ('Hungarians, up!') which was received with shouts of applause; the students of foreign nations, copies, being the first poem printed in Hungary without passing the censorship; and at the theatre that evening, after the great events of the day, it was sung again and again, the whole audience joining in the chorus. His poems, 'Most vagy a fa' (The Tree), and 'Csak a Test' (The Body), had a great influence on the popular mind. He failed however as a candidate for a seat in the National Assembly for Little Kumania, but seized every opportunity of addressing the public to the National Assembly.

When the 1st of August 1848, the two parties of the Moderate and the Extreme Liberals in the National Assembly came to a conflict on the question, if the words of command to the Hungarian army should be given in Hungarian, or as they had always been before, in German. Vörösmarty, who was one of the deputies, gave his vote on the side of the Moderates, who, on that occasion, were first brought into a minority by the party of Kosztbányi. Petöfi, who, only a few months before, had dedicated the collected edition of his poems to Vörösmarty, with a note, 'On this occasion wrote a poetical address to him renouncing his friendship, each stanza concluding with the lines

'I do not hear the Israél from thy brow,
'Tis thy own hand has been it now;'

and in spite of the remonstrances of mutual friends, gave it to the public in the 'c' Elekpekek' ('Pictures of Life'), a periodical he was then publishing in conjunction with Jokai. Soon after he exchanged the pen for the sword, and joined the army of General Miklós and the army of General Dem, who appointed him aide-de-camp. A dispute with General Mészáros, who found fault with the poet's inattention to discipline, induced him to throw up the appointment in May 1849, after being made a captain. The quarrel was between a butcher (the meaning of Mészáros in Hungarian) and a butcher's boy. The approach of the Russians led him to take up arms anew; he again became aide-de-camp to Dem, and shared the last terrible campaign of that spring in Transylvania. After one of the most desperate fights of that period he was seen no more, and it was universally believed that he was one of the slain. His body however was never found, and in 1852 a report was in circulation of his having been found in London and elsewhere, that Petöfi was still alive and in concealment. Six additional years have now elapsed without any tidings being heard of him; his wife has been long re-married, and there seems little probability that he is still among the living. In the first few months of his life, beginning 'Egy gondolat bán engemet,' he expresses a horror of dying in bed, and puts up an ardent prayer for death on the battlefield.

There is a collected edition of the poems of Petöfi up to 1846, in two small volumes, of which a first edition was published at Pesth in 1847, and a second in 1848. Two additional volumes, containing his subsequent works, were seized and suppressed by the Austrian government after the defeat of the revolution of Hungary. Many of them are said to be found in a volume entitled 'Hängök a multbol' ('Sounds from the Past'), published at Leipzig in 1851, of which a German translation by Vaáli and Benkó, with interesting notes, was issued at Brunswick in 1856, under the title of 'Nationallieder der Magyaren.' As the wonderfully didactic elegance of the language is always spoken of as one of the principal charms of the poems of Petöfi, the foreign reader can hardly expect to appreciate them with any approach to the truth of their intention. But there is a lightness and airiness about the songs which make it easy to believe in the effect they are said to produce on the sympathies of an Hungarian reader.

It may be remarked, that though Petöfi has often been spoken of as the blind son of nature, he had, as has been shown, enjoyed ample opportunities of education; and he was in reality well acquainted with the German, French, and English languages and literature. Gyulai, from whose biography of him the most important part of the following is chiefly taken, informs us that in English his favourite authors were Shakespeare, Byron, Moore, and Dickens; and that he was accustomed to call Dickens, from the kindliness which his writings tend to inculcate, a 'benefactor of mankind.' Characteristically enough in a song-writer, he regarded Béranger as 'the world's greatest poet.' His own long poems are very inferior to his short ones; and in prose he can only be considered to have succeeded in reproducing the English of the earlier brothers, and of several rare minerals. In 1823 he discovered that the mineral called uranite was not the hydrated oxide of uranium,
ultimately by brilliant Glasgow, Times whilst Blackwood's his in his "History of Chemistry," forming part of the 'National Library,' published in 1831, when reviewing the progress of analytical chemistry in Great Britain, bore the following honourable testimony to the merits of Dr. R. Phillips—a testimony involving also considerable respect from us as members of the society of science of this country, which thinking men of all ranks perceive to be of daily augmenting importance to the community:—"Of modern British analytical chemists," says Dr. Thomson, "undoubtedly the first is Mr. Richard Phillips, to whom we are indebted for not a few analyses, conducted with great chemical skill, and performed with great accuracy. Unfortunately of late years he has done little, having been withdrawn from science by the necessity of providing for a large family, which has occupied him of this country except by turning one's attention to trade or manufactures."

It was however in the pharmacetical branch of practical chemistry that Mr. R. Phillips's services were most conspicuous, as the confidential function of the editor of this journal of commerce and medicine, in the任职编辑 of the London Philosophical Magazine from 1831, his services were secured as one of its editors, a post he held till his death. The principal articles on subjects of chemistry and mineralogy in the 'Penny Cyclopaedia,' were contributed by him. Mr. Phillips was successively lecturer on chemistry at the London Hospital, at the Government Military College at Sandhurst, at Mr. Grainger's School of Medicine in Southwark, and at St. Thomas's Hospital. In 1839 Mr. (afterwards Sir Henry) De la Beche, who knew that in the first instance chemical investigations of mineral products would be chiefly appreciated by the government and the public, wisely selected him for the appointment of curator and chemist to the Government Museum of Practical Geology in Jermyn-street, an office which he continued to hold till his death, which occurred May 11, 1861, in his seventy-third year, after a very short illness, having been absent from the museum for three or four days only. On the following day, Monday, May 13, the formal opening of the Museum took place, under the auspices of H. R. H. Prince Albert.

On the institution of the Chemical Society of London, in the year 1841, its founder and first president, Mr. R. Phillips bore the honour of being chosen as the first president, his marked likeness to his seniority among English chemists and his distinguished reputation; and although he declined the office they, he became the president in 1849 and 1850. He had been long a subscriber to the 'Philosophical Magazine,' and the 'Chemical News,' and has corresponded with him. He was a kind and helpful friend to many who have become distinguished in science, and who have been enabled to make a comfortable provision. In 1822 the University of Göttingen conferred on him the honourary degree of LL.D.
PHILLYRINE [CHEMISTRY, § 2.]

PHLEGOM, a common name for Moccus. [Moccus]

PHÆLIEA. [CHEMISTRY. § 2.]

PHOSPHATITE, a name proposed for the native Phosphate of Lime derived from organic sources, and usually called Cöppolite. The latter term conveys an impression which is not always wrong, with the part to part of the quantities of the phosphate of lime now obtained for agricultural purposes. In that which is obtained from the Red Crag fragments of bones of large size are constantly present, and it is questionable if any portion of this phosphate has ever been excrementitious and constitutes the component of the detritus of the sea. The more probable origin of these masses seems to be that they are the delir of a huge seapulp of Codæus, sharks, and other animals, which was formed previously to the existence of the beds in which these remains are now found. After which, the animal matter of the bones was gradually washed away, and the large quantities of phosphate of lime found in the water-worn nodules of the Red Crag are thus accounted for. [Cöppolites, § 2.]

PHOTOGRAPHY is both an art and a science. As an art it enables us to draw, depict, or write by means of light. As a science it teaches us how to observe and further to investigate the effects produced by light upon all natural bodies, whether animate or inanimate, mineral, vegetable, or animal. It is comparatively a very new science, having only recently been recognized as a distinct branch of study, and it has already occupied the liveliest attention of nearly all the most eminent investigators in modern science. The names of Davy, Wedgwood, Thomas Young, Wollaston, and others in the last century,而后 of Bunsen, Ritter, Seebeck, Berthold, and Becquerel on the Continent—relate to this effect. Photography is worthy of special attention from the fact that it requires for its rational and thoroughly successful pursuit a knowledge of chemistry, optics, and physics generally, together with an amount of artistic taste and manual dexterity such as must be useful not only for purposes of mental training, but under a variety of circumstances in actual life. The variety of its parts and aims gives it a special charm for those who like to have a pursuit admitting of both activity of mind and muscular activity. It requires no second-external to doors as in close laboratories. Further it has this charm, that while it furnishes problems of the greatest interest and intricacy for the most advanced philosopher in optics or chemistry, it has its practical processes, which may be readily apprehended, and exercised for purposes of utility or recreation by those who are but little skilled in physical manipulations.

The history of photography has been so fully treated of by Mr. Landseer in his Researches into the Art of Photography, and in his Treatise on Photography, and also by the Abbé Moigno, in his Répertoire d'Optique Moderne, that we need not do more here than recapitulate in a brief manner the points of chief interest which they have given at greater length.

In 1799 Peirret noticed that solutions of nitrate of potash and muriate of ammonia crystallized more readily in the light than in the dark. In 1777 the illustrious Scheele writes: "It is well known that solutions of nitrate of silver in acid of nitre, poured on a piece of chalk and exposed to the beams of the sun, grows black. The light of the sun reflected from a white wall has the same effect, but it is much more evident, with white light and white objects. Again, "Fix a glass prism at the window, and let the refracted sunbeams fall on the floor. In this coloured light put a paper strewn with Nano corsa (chloride of silver), and you will observe that this horn silver grows sooner black in the light than in the dark." Senéchel repeated these experiments, and also experimented on the influence of light in the bleaching of wax.

In 1798 Count Remfrod sent to the Philosophical Transactions a memoir entitled "An Inquiry concerning the Chemical Properties that have been attributed to Light."

In this paper the Count attempts to prove that all the effects produced upon metallic solutions by bright sunshine are due to heat. In 1802 Mr. Harrow refused his name, and showed that sodium of mercury were reduced by light alone, and not by heat.

In 1801 Ritter proved the existence of rays in the solar spectrum, which are to be found beyond its visible limits, and which, when they fell on the surface of a body of silver, these researches having excited attention, M. Berard, Seebeck, Berthold, Sir W. Herschel, Sir H. Englefield, Wollaston, Davy, and others, made various experiments which tended still further to confirm the proof that there are additional rays in the solar light which are exercised through its heat; and that the colour of the light was in some way related to this newly observed action of the sunbeam.

Before proceeding to notice the early efforts of those who laid the foundation of the art of photography, with which we are now to be chiefly engaged, we may observe that Priestley, Sénèche, Ingenhousz, De Candolle, Sausure, and Ritter, directed attention to the influence of light upon plants in an interesting and important subject. Others followed in a similar track, still, however, leaving the matter in a comparatively obscure condition. The action of light on the human frame, and on animal life generally, has not yet been fairly investigated. That some special action will be exercised by light on vegetable life and vegetation, is evident, that light will come to be considered as an important element to health as fresh air and wholesome food. It may possibly be that much mental or bodily labour, exercised in the absence of a stimulus of daylight, is directly injurious to animal life. But let us proceed to trace rapidly the art of photography to its source. In the Journals of the Royal Institution of Great Britain for 1803 will be found a paper by "Thomas Wedgwood and Humphry Davy," the first a brother of the famous porcelain manufacturer, the second the Sir H. Davy of a later period. Their joint paper was entitled: "An Account of a Method of Copying Paintings upon Glass and of making Profiles by the Agency of Light upon Nitrate of Silver in solution."

In the following year Davy published a paper which contains the general germs of the photographic art, namely, the application of an optical instrument to impart upon a sensitive chemical surface the images of all natural objects illuminated by the sunbeam, or other source of light. The instruments used by these observers were the camera obscura and the solar microscope; but let us first see how this important invention took shape in the mind of Wedgwood.

According to Davy, Wedgwood first commenced his researches into the art of photography, the camera obscura; and for this purpose, says Davy, "he first used nitrate of silver, which was mentioned to him by a friend as a substance very sensible to the influence of light." This nitrate of silver was applied in solution to surfaces of white paper or leather, and the trace of the light was removed while the plate was slightly moistened with water. Davy quotes the words of the memoir of 1803: "Moistened with solution of nitrate of silver, undergoes no change when kept in a dark place; but on being exposed to the daylight, it speedily changes colour, and, after passing through different shades of grey and brown, becomes at length nearly black. The alterations of colour take place more speedily in proportion as the light is more intense. In the direct beam of the sun two or three minutes are sufficient to produce the full effect; in the shade several hours are required; and light transmitted through different-coloured glasses acts upon it with different degrees of intensity."... "When the shadow of any figure is thrown upon the prepared surface, the part concealed by it remains white, and the other parts being illuminated, may be preserved for ever, or be transferred by the agency of nitrate of silver which has been previously applied, and it is in a high degree permanent. The copy of a painting, or the profile, immediately after being taken must be kept in an obscure place; it may, indeed, be examined in the shade, but in this case the exposure should be only partial. Such a copy, when dry, is in the hands of the common employed, it is not sensibly affected." No means were found to fix permanently the impressions thus produced. And, as regards the primary end of Wedgwood's researches, we are told that "the images formed by means of a camera obscura have been found to be too faint to
produce in any moderate time an effect upon the nitrate of silver." Davy adds, "in following these processes, I have found that the images of small objects produced by means of the camera obscura could be fixed with difficulty on paper.

This will probably be a useful application of the method: that it may be employed successfully, however, it is necessary that the paper be placed at but a small distance from the lens."

The nitrate (chloride) of silver was found to be more sensitive to light than the nitrate. "Even in the twilight, the colour of the moist nitrate of silver spread upon paper slowly changed from white to faint violet; though under circumstances that produced alterations in opaque objects upon the nitrate." Davy concludes with these remarkable words: "Nothing but a method of preventing the unshadowed parts of the delineations from being coloured by exposure to the day, is wanting to render this process as useful as it is elegant.

From this time the art in England slumbered until 1834, when Mr. Fox Talbot, without knowing what had been done, commenced experiments with the same end in view.

But we must now turn to a neighboring country, France. In 1813 M. Niepce, of Chalons on the Seine, was engaged in a task identical in conception with that of Wedgwood. He was endeavouring by means of bituminous varnishes and metal plates to fix permanently the images of the camera, and in May 1816, a portrait of a gentleman and lady were carried out until 1827, in which year he presented a memoir with specimens to the Royal Society of London; but as he kept his processes secret no notice was taken of his labours. Niepce returned to France dispirited. He then had recourse to the method of bitumen on a metal plate, the surface of bitumen laid upon a metal plate, which afterwards engraved by ordinary engraver's acid. The rationale of his process is this: Light is capable of hardening a bituminous surface in such a way that the usual alteration was produced, no longer acted readily upon the altered part of the surface, and therefore only the shaded portions of a partially illuminated plate would yield to such solvents as the mineral naphtith, for example, furnish. But when a metal plate had been exposed to the luminous rays, and the shadows of the shadows, nothing was easier to etch such a plate by aqua fortis, and this was what Niepce did. A plate thus made and prints from it are now in the possession of Mr. Robert Brown, of theBritish Museum. It is to be hoped that it would be placed in the Museum itself.

M. Niepce named his art *Photography.*

In 1829 M. Niepce became acquainted with a M. Daguerre, who was voted for his dioramic paintings, and who was, it is said, a neighbor of Niepce. Daguerre, who was a quack, a charlatan, and a disappointed inventor, exhibited his works to the camera. A deed of partnership was executed between the two experimentalists, and they jointly pursued their labours until the death of Niepce, in July 1833. A new arrangement was then made between his son M. Isidore Niepce, and Mr. Talbot.

At length came the memorable year 1839, when the whole scientific and artistic world was startled at the announcement that objects could be made to draw their own pictures with an accuracy and minuteness quite unattainable by hand.

In January 1839 the first specimens by Daguerre were shown, but the process was withheld until the month of July. This enabled Mr. Fox Talbot to secure to himself the merit of priority of publication of a method by which sun-drawn pictures could be successfully produced. The process of Daguerre was described to the Royal Society in January, 1839, and communicated to the Society a paper, entitled "Some Account of the Art of Photogenic Drawing, or the Process by which Natural Objects may be made to delineate themselves without the Aid of the Artist's Pencil." And on the 1st of February, in the same year, he gave another communication on the method of preparing sensitive paper and of fixing the images obtained. That the two experimentalists, Talbot and Daguerre, were independent discoverers is evident from the dissimilarity of the means by which light and camera obscura being the only means strictly in common.

Mr. Talbot's method consisted in washing letter-paper over repeatedly with alternate solutions of salt and nitrate of silver; at a certain stage a surface was obtained which gave images of objects placed in front of the eye. These images were fixed by immersion in a strong solution of salt and water, in which the unaltered parts of the chloride of silver were soluble. This process was not very sensitive, and was therefore set aside by Mr. Talbot's later discoveries of 1840.

Let us now examine the nature of Daguerre's process called the Vaporotype. A plate of silvered copper is highly polished, and then exposed to the vapour of the chemical element iodine, which imparts to the plate a series of colours, dependent on the quantity of iodine absorbed.

The exposure to the iodine vapor was carried out by placing the plate in a room which was then assumed a rosy tint, or simply a deep orange-yellow, bordering on red. The plate was then sensitive, and had only to be exposed at the focus of the camera obscura in order to obtain a picture of the objects illuminated object. Some minutes were necessary even in full sunlight. The plate was then withdrawn into the darkened room in which it had been prepared, and there it was exposed to the vapour of heated mercury, which has the wonderful property of attaching itself only to the parts of the plate which have been exposed to light; and this deposit takes place in proportion to the original intensity of light of the image. Thus a picture was produced which represented in shades of black and white the original optical image seen on the ground-glass screen of the camera.

A solution of the hypophosphite of soda was used to fix the image by removing the compound of iodine and silver which still veiled in some degree the shadows on the plate. Subsequently Mr. Fizeau improved the appearance of the vaporotypes by imparting to them a warm tinge by this hypophosphite of gold which was thrown down upon the image by a spontaneous electro-chemical action.

The vaporotype process was not sufficiently sensitive to be of any practicability. To Mr. Goddard is due the great improvement of the introduction of a second chemical agent which now enables us to make pictures in a second of time. In 1840 Mr. Goddard combined bromine with iodine and produced an improved process; he published the result in the full weather of November of the same year. Subsequently he took a few seconds; Daguerre's process requiring many minutes, even in a strong light.

One of the best modes of procedure now adopted is the following: Take a plate of silvered copper and polish it by means of tripoli powder and oil of lavender or fine flour applied by cotton velvet; finishing the polish by cloths cotton velvet alone. Then expose the silver to a mixture of iodine and bromine vapor in such a manner that the vapour of the iodine shall act equally upon the surface of the plate, to which it imparts a coating which is seen to be coloured when examined by light reflected from any white surface, a piece of paper for example. As soon as the plate has assumed an orange-yellow colour it is removed, and then exposed to the vapour issuing from a peculiar red compound of bromine with lime, called 'bromide of lime.' Over this it absorbs bromine, and assumes a rose tint, and as this shade of colour has been obtained, the plate must be removed from its exposure to the vapours. The rose colour has deepened into a plum tint. The plate is then ready for exposure in the camera obscura. No time can be spared for these various exposures as temperature influences the process. A few seconds in each case suffice. The plate must be prepared in a room kept at a constant temperature, which is the light of a candle, or that obtained through yellow glass being alone used at the last iodinating, and in some of the subsequent operations. After exposure in the camera the plate is exposed to the vapour of mercuric for a few minutes, the mercury being at a temperature of about 180° F. Here the picture is developed by the action of the mercury upon the bromo-iodised surface, the mercury being, it is believed by some, decomposed upon the plate in proportion to the amount of light which has fallen upon its surface, and which has been reflected by the camera. On its removal from the mercury box the plate is partially fixed by washing its surface with a strong solution of hypophosphite of soda. The final fixation is effected by boiling upon the plate a solution of a double salt, called hypophosphite of soda and gold. This is fixed upon the plate, and may be coloured by brushing over it colours in very fine powder. The image should be kept so as to exclude the vapours of an impure atmosphere such as is usually found in large bell-jars, as these would dissolve and once darken the light part of the image. The film of stannic acid, however, generally, may be removed by a solution of cyanide of potassium.

Having given an account of the daguerreotype, we might proceed to relate the history of Mr. Fox Talbot's researches— which led to the invention of the first successful process in photography on paper; but as these will be found detailed in Mr. Talbot's work "The Pencil of Nature," and in the Specifications of his Patents, we prefer to pass at once to con-
sider a process which has now almost superseded all others, and which certainly sprang out of Mr. Fox Talbot's discovery of the Daguerreotype. It is that of silver nitrate, when used in excess, upon paper, for the purpose of procuring an image which remained latent until developed by a solution of gallic acid. The process now used, and called the Collodion process, was that of Mr. Scott Archer, who consists in depositing a film, on glass, of collodion, containing also iodide of silver with an excess of nitrate, the development being accomplished by pyro-gallic acid in the place of gallic acid. The analogy is complete, but the latter materials improve very much the ultimate results.

Collodion is made by dissolving in ether and alcohol cotton-wool which has been altered in its properties by treatment with strong acids. The following is a good mode of proceeding, and is due mainly to the researches of Mr. Hadow: Take 15 grains of purified starch, 40 grains of gallic acid, 60 grains of tartar, 2 drachms of cochineal, and 1 drachm of oil of vitriol (specifi gravity 1·833 about) 160 drachms, of water 14 drachms; stir together, and when at a temperature of from 150 to 155° Fahr., add, bit by bit, 15 grains of cotton-wool to each ounce of the above mixture. Allow it to stand for four or five minutes, and then wash it many times in water until it is quite free from acid. Then, to make the collodion, take 9 grains of the dry cotton, and add 6 drachms of pure ether (ap. gr. 725 to 730), and 3 drachms of alcohol (sp. gr. 0·8). This mixture should be once dissolved. In another bottle prepare what is called the 'iodinating solution' by taking alcohol (ap. gr. 0·816 to 0·830) one ounce, iodide of potassium 12 grains, iodide of cadmium 4 grains; dissolve the salts in the alcohol, and keep the solution in a closed bottle. Then, while the collodion is being made, wash the glass plate with two drachms of the iodinating solution; this mixture changes by keeping, and should therefore be made only in moderate quantities. Having prepared the iodized collodion, a plate of glass is covered with it by pouring a quantity on the centre of the plate, and then allowing the liquid to flow to the corners in such a way that the glass shall be uniformly covered; the excess is thrown off at one corner into a bottle set apart for the purpose. After a few seconds, the plate is held in the cold hand, and directed firmly to the collodion bath, and left to remain in the bath, or, instead, a weak solution of cyanide of potassium may be poured upon the plate, and left there until the yellow film of iodide of silver disappears. The plate is then washed and dried, and protected by a film of varnish; amber in chloroform being usually preferred for this purpose.

The picture thus obtained is, as in the calotype or Talbotype process of Mr. Fox Talbot, a negative one, that is to say, a picture having its light and shade reversed; though by modifying the collodion process direct positives may be at once obtained; a good negative, however, is a more valuable acquisition. In order to obtain copies correct in light and shade and position, a positive has to be made. There are many processes by which this may be performed; but we will here give only one, which answers perfectly. Take the white of an egg and beat it up, with every fluid ounce of it 15 grains of common salt: remove the froth thus obtained, and continue beating until all has become froth. Leave this froth to itself, and the greater part of the white of egg will become albumin. Pour the liquid into a flat shallow dish, and upon it place carefully, so as to exclude bubbles of air, a sheet of thin paper, French paper is usually chosen; leave the paper for two or three minutes, then dip it carefully in the coated plate, and coat only one side with the 'salted albumen,' as the white of egg is called. Then carefully remove the sheet, and pin it up by a corner to dry. This operation can be carried on in daylight. To make this paper sensitive, it is steeped upon a solution of nitrate of silver, or, if one wishes to work in excess, of starch. Here it is left for two or three minutes, and then renewed and suspended to dry. This last operation must be per-

formed in a room dimly lighted, as in the case of the daguerreotype and collodion final preparation. Upon the dry sheet, the collodion is spread with a watch glass, or any other vessel, so as to cover the whole exposed in a proper 'pressure-frame' to the sun or to daylight. After a few minutes the picture is found printed, and must next be fixed by immersion in a solution of hypo-sulphite of soda, one part of the latter in from 6 to 10 parts of water. Ten or fifteen minutes' immersion would suffice to fix the picture; but in order to produce an agreeable tint of colour, a longer immersion is had recourse to, with the addition to the 'fixing bath' of a few grains of a neutral alkali, such as ammonia. After fixing, excess of silver is removed. After this bath, the picture is removed, and washed repeatedly with plenty of water; hot distilled water being used at last. This fixing bath is made fresh for each day's work. The pictures, when washed and dried, may be mounted on cardboards or protected in glass cases, to injure the picture under some circumstances. Exposure of the finished picture to impure atmospheric vapours, and to damp, is to be avoided. Mr. Maloney has advised that the fixing solution should be heated in solution of caustic potash in order to secure its greater permanency. He also insists on the injurious action of sulphur in certain forms upon the print.

There is another branch of photography which is worthy of the attention of the student, but which has not yet come into practical operation in a perfectly satisfactory manner. It is that of photographic engraving. The labours of Niépce, Grove, Fizeau, Talbot, Pretsch of Polteivin, and others have done much to forward this art, but at present all is too uncertain and too slow to encourage extending this article by a description of the processes.

Stimulated by the experiments of Sir John Herschel, M. Ed. Becqueval and others, M. Niépce de St. Victor commenced a series of beautiful experiments upon coloured flames and the production of photographic images. He laid before the Academy of Sciences, Paris, a detailed memoir upon the subject on the 4th of March, 1861. This was followed by others on June 2, 1861; Feb. 9, 1862; and November 6, 1863. By the method described in these Labours a series of photographs may be obtained on the glass plates which had been rendered sensitive by a chloride of copper, images which faithfully reproduced the colours in coloured engravings, flowers both artificial and natural, lay-figures dressed in stuffs and gold and silver lace, precious stones, etc. These were obtained by, the process of photographic printing in and the camera; the light and brilliant colours being obtained with comparative ease, but the darker and more sombre colours more slowly. The colours he rendered more intense and may be sensitized by the action of ammonium. But beautiful as were the results, and much more nearly as they seemed to approach the solution of the problem of photographing the colours of nature, they proved to be only comparatively permanent. The colours obtained by this method rapidly fade, and the effect is not very durable. This method (mainly due to M. Ed. Becquerel) M. Niépce named Heliochrome. M. Ed. Becqueval, by the use of silver plates, coated with a dark compound of chloride and silver, obtained the decompositions of hydrate of silver, and has succeeded in obtaining coloured images of the solar spectrumbut no method of fixing them permanently has been discovered.

In scientific photography much remains to be done. We know not but the properties of light in its influence on vegetation and animal life. Mr. Robert Hunt and others have, however, established some interesting facts in the former direction, and lately some experiments made upon the eggs of insects seem to show that light of various colours and intensities acts differently according to its colour and other peculiar qualities. There is no branch of science which will better repay the philosophical experimentalist for his investigations than that of photography. The most marvellous and marvellously results have been constantly ob-

tained. As an instance let us take the recent discovery of M. Niépce de St. Victor, which seems to prove that bodies acted upon by the sun absorb its powers in such a manner that they can emit photographically the same kind of influence which they absorb: thus proving that by setting up of light—to speak thus has been arrived at.

Those who would pursue photography further should consult Hunt's 'Researches on Light,' the Abbé Moigno's 'Photographic Alphabet," Ed. Becquerel's 'Travais on Photographic Chemistry,' Thebes! paper also of interest to be found in the 'Comptes Rendus'
of the Paris Academy of Sciences, in our own Royal Society's 'Transactions,' and above all in the journals of the various Provincial Societies. 

PHYGIS, a genus of fishes belonging to the family Gadidae. It has an elongated body; two dorsal fins, the first short, the second long; ventral fins with a single ray only at the base, afterwards divided; chin with one barbule. 

Fishes belonging to this genus are found in the British coasts. It has been taken most frequently in Cornwall. It is about two feet in length, but not very good eating.

PHYLOSTOMA. [CRITZETID.] 

The two commonest diseases of the human system are treated of in the 'Penny Cyclopædia,' either under the head of the particular disease, or the organs or system of organs disordered. In the First Supplement, under the article Disease, a classification of diseases will be found. In the present article, some forms of disease are noticed which have either been recently described or on which new light has been thrown by recent research. The subjects have been arranged for the convenience of reference in the alphabetical form. 

Acclimation is a term applied to that change in the human system produced by residence in a place whose climate is different from that to which it has been accustomed, and which enables it to resist those causes of disease which render such residence injurious to the health of the individual. 

A person is thus rendered similar in constitution to the natives of the country which he has adopted. This subject is one of great importance, and has not yet received the attention it demands. As far as present evidence goes, it appears that in such cases as have been brought under observation, the physical and intellectual development, the greatest amount of health, and reach the greatest age, above 40° in the western and 45° in the eastern hemispheres. Whenever they pass below these latitudes, their health deteriorates, and becomes extinguished. In the northern states of America the mortality of the black population is double that of the white.

The laws of climate show that each race of mankind has its own peculiar and unchangeable limits. All of them seem to possess a certain degree of constitutional pliability by which they are able to bear, to a certain extent, great changes of temperature and latitude; and those races that are indigenous to any country, are better accustomed to shifting sun and colder climates than to the opposite latitudes. The inhabitants of the Arctic regions, as also of the tropics, have a certain pliancy of constitution; and while the inhabitants of the middle latitudes may endanger 30° south or 30° north with comparative impunity, the Eskimians in these latitudes would be regarded as incurably diseased; and on the other hand, do not have to withstand the vicissitudes of climate encountered in traversing the 70° of latitude between Greenland and the equator. The fair races of northern Europe below the arctic zone find Jamaica, Louisiana, and India, to be extreme climates; and they and their descendants are no longer to be recognised after a prolonged residence there. When an Englishman is placed in the most beautiful part of Bengal or Jamaica, where malaria does not exist, and although he may be subjected to no attack of acute diseases, but may live with a tolerable degree of health his threescore years and ten, he nevertheless ceases to be the same healthy individual he once was; and, moreover, his descendants degenerate. He complains bitterly of the heat, and becomes tainted; his plumy plerotic frame becomes attenuated; his blood loses luster and red globules; both mind and body become sluggish; gray hairs and other marks show that age has come on prematurely—the man of forty looks fifty years old; the average duration of life in England is less than in the United States (with insurance tables); and the race in time would be exterminated if cut off from fresh supplies of emigrants from the home country.

Our army medical historians tell us that our troops do not show the same degree of influence and resistance in the distant land affords no immunity from the diseases of its climate, which act with redblooded energy on the stranger from the temperate zones. On the contrary, the mortality among officers and troops is greatest among those who remain longest in those climates.' (Johnson, Martin, Tulloch, Macpherson, Boudin.) Dr. Macpherson also makes the significant remark, that the small mortality among officers compared with soldiers, in India, is due to the greater facilities officers enjoy of retaining their health when they fall sick. Although the constitution of the man may be so modified that comparative health may be retained, yet there is a morbid degradation of the physical and intellectual faculties which eventually takes them back to their native climate, they may yet revert to the healthful standard of their original types. The good effects of limiting the period of service of our troops abroad to three years, has shown this in sustaining for a greater period the strength of the regiments in the more exposed regions of the European regiments in India having been followed by the most disastrous results. "European regiments in India have melted away like the spectres of a dream. A thousand strong man form this year a regiment: a year passes, and one hundred and twenty-five new recruits are required to fill up the broken column; and eight years having come and gone, not a man of the original thousand remains in the dissolving corps."

With regard to the British Fusilier European regiment, for instance, Dr. Arnot has shown that its losses average 104 per 1000 per annum; a loss equivalent to the entire absorption of the regiment in nine years and seven months.

In Bengal also it is an ascertained fact, that a British regiment may be entirely changed by men who have not been in the country for a year, in favourable times, and with all the improved conditions of the service. Dr. Arnot's statistics show that the Bengal army loses annually 9 per cent. of its numbers, giving a total loss in eight years of upwards of 14,000 men out of an army of 165,180 men. (Atikin's 'Handbook of Medicine.')

In the island of Ceylon the rate of mortality has been recorded amongst five different races of which the British troops are composed. The following table gives the result:

<table>

</table>

Although from these facts it would appear there is an insuperable barrier to the prolonged occupation of tropical countries by white races, yet much may be done by attention to the laws of health and disease. One cause of the great amount of mortality amongst Europeans in the tropics is that they are peculiarly inclined to succumb to the effects of hot and humid weather when they arrive in the hotter parts of the world. An attention to diet, clothing, and residence, would do much to remove many of the causes of disease. It would appear also that many of the races that now inhabit cold climates have never been exposed to the climatic conditions that have gradually produced in the constitution, as by the slow advance of peoples north or south, may overcome that tendency to succumb which is so evident in the rapid removals to which the above data refer. The question of the permanent occupation of tropical countries has become one of vital importance to the two great European governments of England and France. How this can be done at the least expense of human life can only be ascertained by the study of the laws which regulate acclimation.

Addison's Disease. The name of Dr. Addison, physician to Guy's Hospital, has been connected with a diseased condition of the system, which is made apparent by a discolouration of the skin. Hence this disease is also called 'Brown Skin.' The existence of this discoloured skin has long been known as a symptom of certain cachectic states of the system; but Dr. Addison was the first to point out that this state of the skin always existed in connection with such a state of the body, as now to be called Addison's disease. These bodies belong to the class of ductless glands, and till the time of Dr. Addison's researches upon brown skin appeared, little was known of their uses and functions in the human body. The following conclusions with regard to these bodies have been arrived at by Dr. Harley as the result of his experiments—

1. The supra-renal capsules are not solely vital organs.
2. They are not absolutely essential to life.
3. The removal of the right is generally more fatal than the left.
4. That convulsions do not necessarily follow their removal.

5. The absence of their function is attended neither by great anaemia nor debility.

6. If death follows an experiment, it occurs as the result of injuring neighbouring parts.

7. Absence of the supra-renal bodies is not proved to have any specific effect on arteriosclerosis of the heart, or in increasing the formation of blood-crystals.

8. The suppression of the supra-renal capular function is not attended by an increased deposit of pigment in the skin or its appendages.

9. The examination of the connection of the bronzed skin and supra-renal capular disease is more likely to be solved in the dead-house than in the physiological laboratory.

These conclusions were chiefly arrived at by experiments on rats, but they would seem to indicate that the connection between the bronzed skin and supra-renal capular is not clearly made out.

The distinguishing features of the disease to which the same bronzed skin has been given, are general languor and debility, great feebleness of the heart's action, irritability of the stomach, a peculiar change of colour of the skin, and these symptoms usually occurring in connection with a diseased condition of the supra-renal capular. The general symptoms are in fact those of anaemia, or cases in which the visibility of the capular function is generally speaking a conduct of the skin, that it usually increases with the advance of the disease. The anaemia, languor, failure of appetite, and feebleness of the heart become aggravated; a darkish streak usually appears upon the commissures of the lips, or the commissures and the under part of the chin may be sunken, and dry harsh condition of the surface so commonly observed in ordinary malignant diseases; the pulse becomes smaller and weaker, and without any special complaint of pain or uneasiness, the patient at length gradually sinks and expires. In one case, which may be said to have been acute in its development as well as rapid in its course, and in which both capsular were found universally diseased after death, the mottled or checked discoloration was very manifest, the patient was restless, morose, marked, and the sickness was great, and vomiting urgent; but the pulse, instead of being small and feeble as usual, was large, soft, extremely compressible, and jerking on the slightest emotion or excitement, and the patient speedily died. (Addison.)

Although the connection between the state of the skin and the disease of the capular was exhibited in all Dr. Addison's original cases, many exceptions have been recorded. Cases have occurred in which extensive disease of the capular has occurred without the sickness of the skin, and cases of bronzed skin have been seen where no disease of the supra-renal capular could be detected after death.

1. Harley, in the paper before referred to, concludes:—

1. That bronzed skin may exist without the supra-renal capular being diseased.

2. That complete degeneration or total absence of the supra-renal capular may occur without any bronzing of the skin.

3. That bronzed skin may be associated with a variety of differently-marked conditions of the system, among which a prominent one is disease of the supra-renal capular.

4. That bronzed skin may be present without any disarrangement of the capular, or characters of the disease occurring without the sickness of the skin, and cases of bronzed skin have been seen when no disease of the supra-renal capular could be detected after death.

5. The blood has been examined by the microscope in some of these cases, and found to present an increased quantity of red corpuscles, and a diminution of the white corpuscles in the disease known as Leucocythemia. (Bloom, Duglass, &c.)

6. The microscopic character of the skin has been carefully examined in this disease, and it has been found to present the same appearance as observed in the skin of the black man of America. (Bloom, supra-renal capular was found to be increased, and existed in larger quantities in the under than in the upper layers of the epidermis.

The treatment of this disease is not affected by our knowledge of its supposed causes. The remedies which would be applicable to bloodless and diseased conditions of the system should be used here. Tonics, nutritious diet, fresh air, and the means resorted to for restoring health in anaemia and leucocythemia may be had recourse to here.

The prognosis in this disease is unfavourable, although cases are reported in which recovery has taken place.

Anaemia, a diseased condition of the human body, in which is implied either a morbid condition of the blood, or a relative diminution of some of its most important constituents. This disease is also called oligonemia and anamonies, terms which, like anaemia, express a deficiency or paucity of the constituents of the blood. This state of the system is generally indicated by the excessive paleness of the face as well as by the weakness of the body. The lips are pale. The conjunctiva is of an unnatural white, having a pearly lustre. The veins on the surface are small, blue, and collapsed. These general symptoms are frequently attended with derangements of the nervous system. There is frequently violent pain in the head, and not uncommonly, ordered sensations, as singing in the ears and flashings before the eyes. The whole surface of the body is frequently naturally tender, the slightest touch causing the patient to start. The course of the spine is frequently excoriated, leading to the supposition that there is spinal irritation.

The circulatory system is deranged; palpitations of the heart on after slight exertION. The pulse is mostly small, feeble, and quick, excited to rapid action on slight exertion. The disease is marked by diminution of the blood-corpuscles, which is generally laxitude and inability to take much exercise. This disease is accompanied with disturbances of the circulatory system, which may be detected by means of the stethoscope. These are heard in the heart, arteries, and veins. The true pulse, the pulse of the capular, and the arterial murmur are heard distinctly. The arterial murmurs are not frequently heard; they are synchronous with the beat of the pulse, and when present may be recognised by the character of the pulse. The venous murmurs are heard more frequently, and may occur; these are various buzzing, humming, musical, and singing murmurs. "They are most frequently heard on the right side of the neck, at the junction of the external and internal jingular vein." (Aitken.)

The venous murmurs are seldom absent to a greater or less extent in anaemia.

When the blood of anaemic persons is examined under the microscope a deficiency of blood globulins is observed. Andral records a case where he observed that blood globulins were 30 parts of blood, and 70 parts of blood corpuscles. In 1000 of blood. The true or normal proportion of the blood, as far as observations at present go, seem to suffer little alteration.

The causes of anaemia are being acting on the system by which the thoroughness of blood is disturbed. They are the development of the blood cells prevented. Thus, amongst the causes of this disease we may reckon: 1. Want of food. 2. Want of proper food. 3. Indigestion or imperfect nutrition, from whatever cause. 4. Derangement of the liver, spleen, &c. 5. Haemorrhages, &c. from hemorhoids, the stomach, lungs, wounds, &c. 6. All extensive discharges from wounds, ulcers, or mucous surfaces.

A knowledge of the causes of anaemia at once suggests its treatment. Where it depends on a want of food altogether, or of improper food, then food of a proper kind should be supplied. Where improper food, as alcohol, produces imperfect assimilation, it must be withdrawn. Deficient nutritive changes often come on as the result of insipid air, and change from an impure to a pure air often acts most beneficially. In certain cases dependent on imperfect blood-cell formation great benefit results from the administration of iron. Cases are recorded in which, under an iron treatment, the blood-cells have increased from 25 to 85 in a 1000. Other remedies which greatly stimulate the blood-forming organs of anaemia in marjor districts quinine is of great service.

Bright's Disease. An affection of the kidneys, having very definite symptoms, and exhibiting uniformity of structure. The disease was found at Guy's Hospital, and is generally called after him. This disease is also called Albuminuria and granual disease of the kidney; the first on account of its diagnostic symptom, albumen in the urine, the second on account of the morbid conditions presented by the kidney. This formidable disease presents
The treatment must be active in the early stages. Purges may be given and blood abstracted locally, and the urine should be perpetually kept clear. For the patient's benefit. When chronic, diaphoresis and diuretics are both admissible. Amongst the former, Dover's powder and warm baths, and the latter, bitartrate of potash and digitalis. The patient should be protected from cold; a warm climate is a serviceable means of keeping the circulation in good working; fresh air and exercise, are desirable.

Blood: Diseases of A large number of diseases are now referred to disordered conditions of the blood. Amongst these are many which are not distinguished by the name of blood. Continued Fevers, Eruptive Fevers, Syphilis, Mercurial Poisoning, Rheumatism, Gout, Scrofulosis, Obesity, Leucocytosis, and Pyæmia. With the exception of the two last, these diseases have been treated of in the "Penny Cyclopaedia." Leucocytosis and Eosinuria is the disease to which reference is made by Dr. Bennett, of Edinburgh, in 1845. The name is derived from the fact, that in these cases the white or colourless corpuscles of the blood are increased in number. This state appears to be brought about by loss of blood, chronic disease, more or less separations of the lymphatic glands and spleen. It is accompanied by debility, wasting, cough or diarrhoea, and a generally unhealthy condition of the system. The increase of the white corpuscles of the blood is not supposed to occur of itself, but is generally dependent on some merited condition which has preceded. The most frequent complication is enlargement of the spleen. Vogel states that in nineteen cases this complication existed in sixteen. Occasionally the spleen shrinks, in which case the increase is found in the lymphatic glands. The lymphatic glands are the organs most extensively affected. The occurrence of this disease has led to highly interesting inquiries as to the origin and nature of the white cells of the blood, which are increased in such of these cases. Dr. Bennett, in his work on the "Penny Cyclopaedia," (1868), gives the following conclusions as to the result of his own elaborate and carefully conducted inquiries:

1. That the blood-corpuscles of vertebrate animals are originally formed of lymph-corpuscles, which are separated from the lymphatic blood, whilst healthy urine has a specific gravity of 1.080. It contains less urea than healthy urine. Under the microscope it also presents appearances indicative of the nature of the disease. These appearances are more marked in the tubules of the kidneys, formed by substances produced in various stages of the disease. They are thus classified by Dr. Bennett:

2. Exudative casts, consisting of the coagulated exudation or fibrine which is poured into the tube during the inflammatory stage.

3. Desquamative casts, consisting of masses of the epithelium lining the tubes, and occurring in all stages of the disease.

4. Fatty casts, consisting of patches of epithelium as in the last, but which have undergone a fatty transformation by the accumulation of a greater or less number of fatty granules in its cells.

5. Waxy casts, presenting an exceedingly diaphanous and structureless substance. They are frequently associated with the two last.

Dr. Bright originally described three stages of this disease, but later observers have recognised six.

1. The papillary form, in which the kidneys are enlarged, and show an increase of blood in the tissues. In this stage only a small quantity of urine is passed containing the exudative and desquamative casts.

2. In this stage the kidney is enlarged to nearly double its normal size. The tubes of the kidney are obliterated by the inflammatory deposit.

3. The kidney presents a mottled appearance. It is probably a transition from the first to the second stage.

4. In this stage the kidney is large, dense, and white. The tissues of the kidney have become changed. The urine is scanty, of low specific gravity, and defective in urea and other excretory matters.

5. In this stage the kidney is hard, granular, and contracted. The kidney is smaller than in health, the surface is uneven and puckered, the tunica adherent. There is no deposit in the tubes, but fibrous matter has been deposited in the substance of the kidney, and the tubes are strangulated. The urine may not contain albumen. Its specific gravity is sometimes as low as 1.005.

6. This stage has been called the "coarse kidney." The organ is large and dark. The specific gravity of the urine is high, and is loaded with albumen. The presence of fatty matter in the casts of the kidneys may occur in any of these stages, and does not appear to exist as a separate form of the disease.

The cause of this disease is a thing which will undiscoverably elude the efforts of the medical art. Thus it comes on as the result of spirit drinking, which powerfully excites the action of the kidneys. Exposure to cold and diminution of the action of the skin will also produce it. It comes on frequently after scariasis, when the skin is highly susceptible of any diminution of temperature.
odour, the lungs are congested, the skin becomes daily more yellowish, articulate swellings with swellings in the intra-synovial cavity occur successively in several of the joints. The tongue is dry, and coated with a brown fur; the teeth and lips are covered with sores, the abdomen is tender and frequently tympanitic, the pulse is quick and becomes tremulous and rapid, the eyes become dull, and yellow, and yellowish yellow in self, the voice is lost, and the patient sinks from the fourth to the tenth day.

After death abscesses are found in the lungs, liver, spleen, brain, kidneys, heart, pleura, joints, muscles, and the subcutaneous parts. 

In many cases pus-cells, or an increase of the white corpuscles, have been found in the blood. This increase is not, however, a diagnostic symptom, as many cases have occurred in which pus-cells have been observed in the blood (which are not easily distinguished in the blood from pus-cells, and have been supposed to be identical) has been observed.

The pathology of this disease has excited much discussion. While some have regarded it as entirely dependent on the introduction of gas into the blood, others maintain that it depends on the introduction of a peculiar poison into the blood. Dr. Bennett injected pus into the blood of an ass without producing ill effects, and the above symptoms come on without any introduction of pus from without. It is more probable that the disease is a peculiar state of the blood, either arising from vital changes in itself, or produced by the introduction of an external poison.

The disease is most frequently fatal, and no one plan of treatment can be laid down. Where suppurating surfaces are present these must be attended to, and accumulations of pus in abscesses should be removed by free incisions. The system must be supported by stimulants. Large doses of quinine have been recommended, and the patient is very frequently left to the integrity of the pulse, and frequent pulse, terminating in from two to seven days, and having for its cause excess, exposure, over-fatigue, &c. (c. e.) the cause of febricula is not specific.

"Fibrilicula.—A disease arising from a specific cause, attended by rigors and chilliness, headache, vomiting, white tongue, epigastric tenderness, confined bowels, enlarged liver and spleen, high-coloured urine, hot and dry skin, and frequent pulse, terminating in from two to seven days, and having for its cause excess, exposure, over-fatigue, &c. (c. e.) the cause of fibrilicula is not specific."

"TYPHOID FEVER.—A disease arising from a specific cause, attended by rigors, chilliness, headache, successive crops of rose spots, frequent pulse, sonorous rcle, diarrhoea, fulness, renaissance, and tenderness of the abdomen, gurgling in the right iliac fossa, increased splenic dulness, delirium, dry and brown tongue, and prostration, and terminating by the 30th day. After death enlargement of the mesenteric glands, disease of Peyer's patches, enlargement of the spleen, disseminated abscesses of the lungs, &c."

"Tuipaus FEVER.—A disease arising from a specific cause, attended by rigors, chilliness, headache, bulimy rash, frequent pulse, delirium, dry brown tongue, and prostration, and terminating by the twenty-first day. After death, disseminated abscesses of the lungs, &c."

"(Medical Times, 20th Paper.)"

On the other hand, Dr. Duncan of Liverpool maintains, that there is no specific difference between the various kinds of contagious diseases, and that there is no distinction between this and intermittent or remittent fevers. All these, he maintains, belong to one form of disease, and are curable by one remedy, and that is quinine. He prescribes ten grains of the sulphate of quinine every two hours until five or six doses are taken, and states that it cuts short all forms of fever in the same way as it does intermittent fever or any other disease.

This practice has been followed by many medical writers with favourable results, but with others it has entirely failed. Dr. Bennett of Edinburgh tried this remedy in nineteen cases, which he has related in his "Chemical Lectures," but the result of these cases was not favourable to the use of this remedy.

Daresia (Scarlina febris) is a peculiar fibriluse disease, conjoined with sudden severe pains in the small joints, which are usually swollen. It is accompanied by heat of skin, intense pain of the head and eyeballs, and the appearance of a cutaneous eruption on the third or fourth day. It is attended by paralytic symptoms on the part of the nerves into which the disease develops itself epidemically. The chief peculiarity of this disease is the combination of the symptoms of an exanthematic fever with rheumatic or neuralgic affections of the joints.

This disease was introduced into this country by an emigrant from France. "It has been chiefly prevalent in Rangoon, Calcutta, Berberapmore, Benares, Chunchighur, in the East Indies; the island of St. Thomas in the West Indies; the Southern States of America; the ports on the Gulf of Mexico; the towns of New Orleans, Savannah, Charleston, Philadelphia, and New York. It was epidemic in 1824-28, and nothing appears to have been heard of it again till 1849 and 1850, when it again visited the Southern States of America."

The general course of this disease is that the patient is attacked by pricking pains of light, chilliness, and pains in the back and joints. The small joints swell, the skin becomes hot, the pulse frequent, and the face flushed. The tongue is red. Sometimes an eruption appears at this stage, which, however, is of short duration. After two or three days, after which it subsides, leaving the patient very feeble. This remission is, however, only temporary. In the course of two or three days there is a return of the fever and pains, with a thickly coated tongue, nausea, and tenderness of the epigastrium. On the sixth or seventh day a scarlet rash appears on the hands, which rapidly spreads over the whole of the body, and gives relief to the febrile irritation. The eruption is very irregular, sometimes being smooth, but at others being papular, vesicular, purpuric, or even furunculous. The symptoms of the disease do not diminish, but assume some rheumatic stiffness, and feelings of weakness and mental depression. During the last epidemic at Calcutta the throat was sore, and the articular symptoms were less obvious.

The treatment of this disease consists simply in the palliation of the symptoms. When the nervous irritability and pain are considerable, then opium has been found of essential service. The disease might at first sight be regarded as a mild form of typhus. Some of the symptoms, however, are sufficiently characteristic.
membrane is found in the larynx or trachea, it is always subsequent to its appearance in the fauces. At the commencement of the disease, the membrane is seen in the form of a white spot on the pharynx or tonsils, from which it gradually extends all around. As it goes on, the membrane comes away in spots or patches, which, when a large membrane may be seen of a deep red or even of a purplish and olaire colour. During the progress of the disease the cervical and submaxillary glands become swollen, and there is a fetid discharge from the nose and mouth. As the slough succeeds the discharge, it is mixed with pus, and looks as if a hearth were gradually occuring.

The general symptoms are those of low fever. The disease sets in with shivering and intense depression, there is dryness and tingling of the throat and ears, difficulty of swallowing, and tendency to vomit. It is necessary to load the tongue is loaded, the pulse is frequent and feeble. In the early stages it might be taken for scarlet fever. But there is no active fever, no eruption of the skin, no redness of the papilla of the tongue, and when the patient recovers, no desquamation of the cuticle as is constantly the case in this disease.

The prognosis in these cases is unfavourable. This disease generally terminates life by extending to the air passages and producing effusion in the glottis, which speedily terminates life.

This disease is from the beginning attended with a great depression of the vital powers, and its treatment demands that the vital processes should be sustained. A purgative may be given at the onset, but in most cases wine may be administered. The writers also give a mixture of the chlorate of potash administered in the same way as in scarlet fever. To this may be added the preparations of ammonia. Quinine has also been highly commended, with the mineral acids. The throat also requires treatment, and the tonsils when large should be employed, nitrate of silver and chloroform. The nitrate of silver is applied in the proportion of one dram to an ounce of water on a sponge several times in the course of the day. Dr. Watson recommends chloroform in the case of children. This relieves the febrile smell which is very disagreeable to the patient and those around.

This disease occurring in districts, and attacking in succession the members of a family, has led to the conviction that it is contagious. As it is so dangerous a disease, it would be well to act on the doubt, and to take those measures which would be adopted in the case of contagious diseases, as small-pox and scarlet fever.

Glanders or Farcy is a name given by veterinary oppo to the disease of horses, and other cattle. It appears in the form of a suppurative disease of the mucous membrane of the nose and of a pustular eruption. The former is sometimes called glands and the latter farcy, but the two often occur together, in the same individual or in the same animal.

In 1821, Mr. Muscroft drew attention to the fact that this disease could be communicated from the horse to the human system. In the same year cases occurred in Germany, and since then it has been demonstrated by a large number of cases that this disease often spreads from the horse to man. When it attacks man it is characterised by vascular injection of the nasal mucous membrane, on which cherry-like sores are formed, extending to the frontal sinuses and neighbouring mucous surfaces, from which a profuse and offensive discharge flows. At the same time a tubercular or pustular eruption appears upon the skin, followed by purpurating bloody or gangrenous ulceration in various parts. These symptoms may be either acute or chronic. In the acute case a blood filled vesicle appears, which being covering, in chronic cases the local affection alone presents itself. The acute disease is ushered in by rigors, pains in the back and limbs. These symptoms are followed by phlegmonous tumours in various parts of the body, which are accompanied with pain and tenderness, and in abscesses or buboes a purulent pustular eruption appears upon the skin, followed by purpurating bloody or gangrenous ulceration in various parts. The disease is ushered in by rigors, pains in the back and limbs.

At the same time a discharge takes place from the nostrils of a matter more or less purulent, viscid, and mixed with blood. The eyeballs frequently become tumefied, and discharge a thick viscid matter like that from the nose. In two or three days the membranes on the face, trunk, and limbs are preceded and accompanied by profuse and fetid sweats. The eruption is scattered, and resembles, according to circumstances, the vesicles of cow-pox or the pustules of the plague. It is sometimes accompanied with large vesicles (bullae), which become black and discharging gangrenous sores. At first the pulse is full and quick; but it becomes rapid, small, irregular, and intermittent. The tongue is at first loaded with white fur, which afterwards becomes brown or black. Diarrhoea and dysentery often occur in the course of the disease. This disease is generally fatal from the seventeenth to the twenty-first day. In the chronic cases the febrile symptoms are not so acute as in the former, but the local symptoms are the same, but they progress more slowly. The abscesses are attended with a large amount of subcutaneous inflammation. In this state patients may recover, but they die from a fortnight to a month. A twelvemonth has been known to elapse before a person has been cured.

There is no doubt that these symptoms are the result of a poison introduced into the system by the horse. In all cases contact with glandered horses has been ascer-

The disease is very malignant, and the glands have been removed, but the disease has been produced. The disease has also been produced by compelling animals to swallow the poisoned matter in their food. There can, therefore, be no doubt that the poison can be absorbed both from mucous and cutaneous surfaces. This being ascertained, it becomes more than ever necessary to prevent contact with glandered horses. Such horses have been known to give disease to persons riding behind them or swimming near them by the water from the nostrils into the air. All glandered horses ought to be destroyed. In Germany the conviction of the danger of this disease is so strong, that all horses proved to have come in contact with glandered horses are destroyed. Not only can this disease be communicated from horse to horse, and from the horse to man, but cases have occurred in which those attending glandered individuals have become affected. The poison of glanders soon manifests itself. Turner inoculated two young donkeys, and in one the maxillary glands became tender on the second day, and the discharge took place from the nose on the third day, whilst in the second the glands became swollen on the third day, and the disease terminated in suppuration. A case has been recorded in which the incubation of the poison must have taken at least three months. In the human being the poison has remained latent from two to eight days after exposure.

This disease in its acute form is very fatal. Of fifteen cases recorded by Rayer only one recovered. Of the treatment, therefore, little can be said as a matter of experience. The general symptoms in the latter stages are those of low malignan fever, and a stimulant plan of treatment is indicated. Observations are wanting, and the swelling may be cupped, but there is no reason to believe that the bleeding did any good. In the chronic forms of the disease recovery is more frequent. The symptoms indicate the necessity of a cautious and prolonged course.

Micrococcus Disease. The recent improvements in the construction of the microscope have not only rendered this instrument necessary in physiological and pathological investigations, but essential as a means of diagnosis in many discussed conditions of the human system. The very general demand for this instrument as an important aid to the eye in examining minute structures and objects, has led to the construction of various forms adapted for the use of the medical man. The description of this instrument will be found in the article Microscope, and an account of the methods of using it under Microscopes, Ums or, in the second supplement of the 'Penny Cyclopaedia.' In the present article the application of this instrument to the diagnosis of micrococcus disease will be referred to, and the subject may be divided under the two heads of Diseased Structures and Diseased Secretions.

Diseased Structures.—1. Cancer. The distinction between cancer and other forms of diseased structure in the human body is one of the most important departments of diagnosis, as upon this depends a just estimate of the action of any particular system of treatment, and the solution of the question of the curability of cancer. There can be no doubt that cancer is the most important of these forms, and we have no claim to be regarded as such; whilst others, with a true cancerous character, have been overlooked. Although the microscope cannot in all cases decide the character of a questionable ulceration, it has nevertheless thrown great light on the subject, and we think that it is an instrument of great importance in their determination. Cancerous exudation generally presents three forms, which, however, are constantly found running one into the other. These have been
PHY 512

named *schirrhous*, *emphaloma*, and *colloid cancer*. In all these forms certain cells are discovered by the aid of the microscope, which have been called cancer-cells. These cells may be spherical, ovoid, cubical, oblong, square, heart-shaped, or of other indescribable forms. In size they vary from the 1/30th to the 1/20th of an inch in diameter. The wall of these cells, when young and smooth is indistinct, but when old it becomes thickened and more or less corrugated. These cells contain in their interior always one nucleus, often two, and sometimes a larger number. These nuclei vary in size. Besides the nuclei the cells contain a colourless fluid, which is at first clear, but afterwards becomes opalescent from the presence of a great number of granules. If water be added to the water the cells become enlarged by its absorption into their interior. On adding to these acetic acid the young cells become absorbed, whilst the older cells are rendered more transparent, and the nuclei remain unaffected, or become thinner fibrous. In *schirrhous* these cells are found either in distinct cysts or amongst a mass of filaments which vary in size, and run in different directions, sometimes forming waved bands, and at others an inextricable pleasia. In emaphalomas the same fibrous structure is observed, but it is looser. In the softer parts no traces of fibres are observed, and the cancer-cells abound. When blood is extravasated in this structure, it constitutes the form of cancer known by the name of thrombomatous cancer. The cancer-cells, however, also to consist of a fibrous structure, but which is so arranged as to form argilae or loculi, which are filled with a grey or amber-coloured glutinous matter. This matter is sometimes quite unchangeable, at other times it presents the necrosed cells characteristic of cancer.

Sometimes the cancerous matter is found mixed with oil globules, and crystals of cholesterol and margaré. At other times it becomes hardened by the deposit of calcareous substances. This indicates the tendency in the production of cancer to assume the forms of fatty and mineral degeneration. (Bennett, Principles and Practice of Medicine.)

2. Tubercle. This form of disseased structure is found in the image of persons laboring under phthisis. It generally presents itself to the naked eye by white patches, a semi-transparence varying from that of cream to a substance resembling tough bose. "A small portion, sponged between glasses and examined under the microscope presents a number of irregular shaped bodies approaching a round, oval, or triangular form, varying in their elongated diameters from the 1/20th to the 1/10th of an inch. These bodies contain from one to seven granules, are unaffected by water, but rendered very transparent by acetic acid." (Bennett.) These bodies are generally spheroidal, oval, or oblong. They are composed of molecules and granules, in a greater or less number, according to the consistence of the tubercle. When the tubercle becomes hardened by calcareous deposits, few of these minute corpuscles surround the mass of irregular particles of phosphate of lime, and crystals of cholesterol.

In the earlier stages of tuberculous deposit of the lungs, the system is found to contain small portions of the disintegrated tissue of the lungs, and in some cases this appearance has been observed when no physical or other decided indications of tubercle existed.

3. Blood. In some forms of the disease the blood-cells exhibit a changed character, which can alone be detected by the microscope. This is seen most remarkably in a disease recently discovered by Dr. Bennett, of Edinburgh, called "Leucocytosis," in which the white corpuscles of the blood, which are much fewer than the red in healthy blood are found to be greatly increased in number. [Bloor, Dundas Cl.]

In many diseases the blood presents an unusual degree of thickness. In this condition the red corpuscles easily lose under pressure their rounded margin, and assume a candate or flask form. They do not aggregate together in the same form of rolls, but present masses of an irregular shape.

In blood produced by internal hemorrhage the red cells readily break down and are partly dissolved. The liquor sanious is also milky, and it is also to contain a large number of granules. In these conditions also the blood-cells frequently present nuclei in their interior.

In cholera the blood has been observed to undergo a remarkable change. Dr. Bennett states, that in blood he examined the red corpuscles were paler than usual, the colourless ones were normal, and mingled with these were others which varied both in shape and size. The latter were generally circular, but some were oval and a few circular. Their long diameter varied from the 1/20th to the 1/40th of an inch, and their transverse diameter to the 1/20th of an inch.

In certain cases the serum of the blood presents a milky appearance, and on being allowed to rest a creamy pellicle is formed on its surface. It is found to be composed of minute particles of oil, which resemble the smaller molecules found in milk and the chyle.

The blood has been observed to undergo other changes, observable by the microscope, in conditions of phthisis, fever, and some other acute and chronic diseases; these have not however been sufficiently accurately described to be relied on at present as a means of diagnosis.

4. Pus. It becomes sometimes a matter of considerable diagnostic importance to detect the presence of pus-globules in the blood. These are composed of mere granules or these have been mingled in a second membrane. At other times they are not perfectly globular, presenting a greater or less irregularity of their margins, and accompanied with granules and molecules. This occurs in pus from malignant ulcers and other kinds of what is called unhealthy pus.

5. Vomited Matters. It is frequently of importance to examine the matters thrown up from the stomach by vomiting. One of the most interesting results of the application of the microscope to these objects has been the discovery of a plant which has been called *Sarcina Venerilis*. Occasionally other forms of plants have been found in the vomited matters, although these have probably been introduced from without. In cases where poisons have been taken which produce vomiting, the application of the microscope will detect the kind of poison. In this way the husks of the ripe fruit of the Deadly Nightshade, the seeds and leaves of *Locelia subfusis*, and other poisonous substances, have been discovered. By the aid of the microscope, we can ascertain the nature of the food taken by children or insensible persons who can give no account of themselves, and this can be done by the examination of the vomited matters. In the stomach, the mucous surfaces of the stomach are affected with inflammation, and the discharges from the stomach will afford indications of the nature of the disease.

6. Feces. The contents of the bowels, when examined by the microscope, often afford important diagnostic indications. They contain naturally the matters secreted by the mucous membranes of the intestines and the remains of the food. They will also contain various morbid products. Amongst these latter may be mentioned plants and animals. Confera and fungi have been found in the feces, and various organic bodies, now known to be introduced from without, were at one time regarded as the cause of cholera. The presence of pus- and blood-corpuscles may also indicate diseases of the kidney, and the remains of epithelial cells of the membrane of the bladder. In cholera the rice-water evacuations consist of mucus and the remains of epithelial cells. The nature of the food in an injurious character may frequently be discovered, by the aide of the microscope, in the feculent matters.

7. Cutaneous Forms of Plants, belonging to the orders Conérfus and Fungi, frequently accompany diseases of the body. These are mentioned in the article *Erörosvita*, S. 2.
sclerotic heads of *Echinococcus* and *Oxyuris* can only be distinguished by the microscope, and are diagnostic of the nature of the cysts in which they are found. Among the articulated animals producing disease, and only to be detected by the microscope are the Scolex, producing the hook, and the *Dendroschistos follicularum* which inhabits the follicles of the skin.

9. Degenerated Tissues. — The tissues of the body are liable to have their normal constituents replaced by substances which are not natural. The nature of these degenerations can only be definitely made out by the aid of the microscope. Thus the muscular tissue is liable to have its sarcous elements replaced by fatty matter, causing fatty degeneration. In the heart, it becomes one of the most serious lesions to which this organ is subject, and is a frequent cause of fatal results. It has also been recently shown by Virchow and others, that starch is present in the tissues of the body, and to this form of degeneration the term amyloid has been applied.

**Diseased Secretions.**

1. Urine. — This fluid contains various salts and histological elements which can only be detected by the microscope. Many of these are very characteristic of diseased conditions. (Bairns's Diseases, S. 2; Microscope, vols. 1 and 2.)

2. Saliva. — This secretion shows various alterations dependent on disease of the mucous membrane of the mouth and tongue. The epithelial scales naturally found in the saliva are altered in their character and structure. Sometimes they are in large numbers, and in such cases are easily obtained from the mouth. The characteristic appearances of the fur on the tongue, under the microscope, is yet a desideratum in the practice of medicine.

3. Mucus. — This secretion is found on all healthy mucous membranes. When the membranes become diseased, this secretion is changed in its character, and various conditions indicative of the nature of the change may be observed under the microscope. In inflammatory affections, the so-called mucous-corpuscles, which resemble those in the urine, are increased in number. The mucus contains also epithelial cells, which may be changed in their character from morbid conditions. These corpuscles and cells are contained in a viscous fluid, which contains a very readily coagulable albumen.

4. Milk. — Diseased conditions of the milk can be determined by the microscope. In a healthy state it contains oil-globules which float to the surface of the liquid, and the whole of an inch in diameter. These globules are enclosed in a membranous envelope. In healthy milk they are of a perfectly globular form, and roll freely over each other. In unhealthy milk the globules are of various sizes, and when acid they run together in masses. A few days after the birth of the young, these globules are mixed with others of a larger size and a more variable size. They give the milk a yellow colour, and it is then called colostrum. They should disappear in the human milk the fifth or sixth day after parturition. If they remain longer, the milk must be considered unhealthy. Milk can be obtained from the mammary during the early months of pregnancy, and its peculiar characteristics are easily distinguished by the microscope. Under such circumstances it is called colostrum, and its history is of the greatest importance.

**Worms.** — The researches of Siebold, Küchmeister, Leuckart, Rainey, and others have recently thrown much light on the history and development of these parasites of the human body. The following is a classification of the various forms of worms found inhabiting the human body as given in Dr. Lankester's translation of Küchmeister's work on the Animal and Vegetable Parasites attacking the Human Body.

**Division Anthoidea.**

**Order Scolecod.**

**Section Platyhelminthes — Flat worms.**

Family *Taeniidae — Cestodae.*

- *Dionoeocephala latum* — Broad Tape-worm.
- *Taenia solium* — Common Tape-worm.
- *Taenia medinensis*.
- *Taenia nana*.
- *Taenia f (Cape of Good Hope).*

The practical conclusion to which these researches lead, is the necessity of preventing the introduction into the system of the egg-shells or of the various forms of tape-worms which produce the cystic and uterine states of the worm, are introduced into the stomach by water, salads, and all kinds of unclearly food. The cystic worms themselves are introduced through the medium of raw or partially cooked flesh, especially pork, which should be carefully avoided.

PLATA, LA, STATES OF. The historical notice of the Argentine Confederation has been brought down to 1836 [Planta, La], when Rosas had been created governor, or captain-general, with almost dictatorial power. By this arrangement the provincial government of Buenos Ayres was invested with extraordinary powers, and temporarily charged with the transaction of all matters appertaining to the common interests of the confederation, and the carrying out of its business with foreign nations. Rosas had previously served as governor and captain-general of Buenos Ayres for the usual term of three years, and had obtained unrivalled influence in that province, chiefly through his military powers, as displayed against the Indians. His decision and energy secured for a while internal peace, and the province began to recover from the effects of the long prevalent anarchy. But cruelty and despotism marked his sway at home, and his ambition, which continually prompted him to extend his power over the provinces, was opposed by the whole country, watered by the Plata and the Paraná, led him into disputes with foreign powers: and these ultimately brought about his downfall. His commercial policy had for its object to secure to the Ayres the monopoly of the trade of the Plata, his political policy to obtain a like territorial superiority. On the death of Francis, dictator of Paraguay, he refused to acknowledge the independence of that power, insisting that it should join the Argentine Confederation, at the same time to render to the navigation of the Paraná by vessels bound to Paraguay. Lopes, the new dictator of Paraguay, therefore entered into alliance with the Banda Oriental, now called Uruguay, with which Rosas was at war. These powers applied for assistance to Brazil. The war was prolonged, and hostilities were opened against the Plata and the Paraná was in a state of confusion. On the earnest appeal of the merchants and others interested, Great Britain volunteered her mediation, but it was rejected by Rosas who marched his troops within a few miles of Monte Video, which was then the same as the capital of the Plata. The emperor of Brazil now interfered, and sent a special mission to request the interposition of the courts of London and Paris. The British and French governments in February, 1846, decided on the 28th of March to send their ambassadors to the Plata to offer mediation, and to announce their intention to enforce a cessation of hostilities if needful, by an armed intervention. The offer was rejected by Rosas, but readily accepted by his opponents. The united fleet of England and France at once commenced operations by seizing the fleet of Rosas which was blockading Monte Video, and the island of Martin Garoé which commanded the entrances of the Paraná and the Uruguay. The harbour of Buenos Ayres was at the same time declared under blockade, and an appeal was made to other nations. The offer of mediation was refused by Corrientes any merchant vessels that might desire to ascend that river. Rosas on his part made hasty preparations to intercept the fleet by planting batteries with parks of heavy artillery at the mouths of the river. The British fleet was, however, the first to pass down the river, supported by 24 vessels and 10 fire-ships. On the 10th of November, 1845, the combined fleet consisting of eight sailing and three steam vessels forced the passage with trifling loss to itself, but entirely destroying the batteries, and expelling the enemy from the mouth of the river. On the 13th of that month, the fleet, with a convoy of 110 vessels, it was encountered at San Lorenzo by a very powerful battery which Rosas had erected in an admirable position, in the full expectation of stopping the passage of the British fleet. One of the number of the Prima, and crippled the naval force. The battery commanded the river, and was difficult of attack by the steamer, but it was speedily silenced by a rocket-bridge, which had been the previous night secretly landed on a small island in the river. The combined fleet escaped with trifling loss, the rocket-bridge lost not a man; but four of the merchant vessels which, through unskilful pilotage, ran ashore, were burnt to prevent them falling into the hands of Rosas. The loss to the Argentine army was very great. Again fleet of merchant vessels were destroyed, and Rosas was forced to yield; and England withdrew from the blockade in July, 1846. It was however continued by France until January, 1849. On the final withdrawal of the two great powers in 1850, Rosas the dictator of Paraguay, in active conference. The armies of Rosas, essentially despotic, and devoted to the maintenance of the supremacy of Buenos Ayres, had moreover become intolerable to the provinces which desired a federal and equal union. Accordingly, towards the close of 1850, Brazil, Uruguay, and Paraguay entered into a treaty, by which the Corrientes and Entre Rios, as represented by General Urquiza, became parties, by which they bound themselves to continue hostilities until they had effected the deposition of Rosas, whose power and tyranny they declared to be "incompatible with the peace and happiness of this part of the world." Early in the spring of 1851 a Brazilian fleet blockaded Buenos Ayres, and soon after an Argentine force commanded by Urquiza crossed the Uruguay. The struggle continued as usual, and Rosas, when asked whether he had hoped to bring the army of Rosas in Monte Video, made a show of resistance, but it was merely to gain time in order to complete his arrangements with Urquiza, and he soon after capitulated. His soldiers for the most part joined the army of Rosas, who at the head of a force amounting to 30,000 men, crossed into Buenos Ayres. A general engagement was fought on the plains of Moron, February 2, 1851, when the army of Rosas was entirely defeated. Rosas, who was entirely surrounded by the enemy, committed suicide, and the army was taken, and the field and, in the dress of a peasant, he reached in safety the house of the British minister at Buenos Ayres. From thence, with his daughter, he proceeded on board H. M.'s steamer Locust, and on the 10th of February sailed in the Conde de Monteleone for the French island. But the fall of the tyrant did not bring peace to the unhappy country. Urquiza, by the governors of the pro-
PLA

PLU

vinces assembled at San Nicolas, was invested with the chief power; and appointed Provisional Director of the Argentine Confederation. The radical faction and the wealthy people of Buenos Ayres, however, declared against him, and protested against the proceedings of the convention, on the ground of the superior privileges of Buenos Ayres being nullified. Uruguay dissolved the Chamber, and insurrection broke out. Civil war commenced with the declaration of war in February, 1813; but on the 20th of December, 1814, the separation of Buenos Ayres from the other states of the Argentine Confederation was settled by treaty; and it has since been acknowledged as a separate state, with a liberal constitution, and independent of the Spanish government. The republic of Buenos Ayres is briefly described under Plata, as one of the provinces of the Argentine Confederation. The capital city is described under Buenos Ayres. See Nicolau de los Ríos.

They are natives of the Levant and North America chiefly. They are fine trees, but their timber is not durable.

There is but one genus (Platanus) in the order and six species. [Platanus.] The family resembles Artocarpaceae and Althaeaceae.

P. PLATANIERA. [Tortoise.] PLEADING, AT LAW AND IN EQUITY. Although modern Statutes have made several alterations in the procedure of the Superior Courts both of Law and Equity, the outline of the system of pleading in use in those Courts, which is derived from the Customary, and which is said to be the law of England, is still substantially accurate. The more important changes effected in the procedure of the Common Law Courts have been mentioned under ABSTAINMENT [S. 2], IMPROVEMENT [S. 2], and MAGNUS [S. 2]: those in the Court of Chancery under EQUITY [S. 2]. It may be added here that the system of pleading devised for the new Courts of Probate and Divorce, is of the nature of that now in use in the Courts of Common Law.

For the most part the genera of Plants belonging to the alliance Algae, the order Ceramiales, and the sub-order Sphaerococcus. One of the species, P. Helminthocoron, is called Corsican Moss, and has a considerable reputation as a vermifuge. It is a native of the Mediterranean.

P. PLATYTOPHORA. [Flag.] PLUNKETT, WILLIAM CONYNHAM, 1st Lord Plunkett, of Newton, County Cork, was the second son of the Rev. Thomas Plunkett, a Presbyterian minister at Ennis, in the county of Clare; his son William was born in July 1764. Having some scruples as to the received doctrine of the Trinity, the elder Plunkett removed to Dublin, where he became minister of the Strand-street chapel. His eldest son practised for many years as a physician in that metropolis, and bequeathed to his brother a large library and a considerable fortune. William was still a boy when his father died, leaving the care of his family to the priest and zeal of his congregation. His dying request was not in vain, and the same received by their assistance a good education. William was in 1783 appointed to the regency of the public scholarship and a degree, and where he was the friend and contemporary of the late Dr. Magee, archbishop of Dublin. Mr. Plunkett was called to the bar in 1787. He had already gained some reputation by his speeches delivered in the debating club of the university, now known as the Historical Society; and the late Earl of Charlemont soon afterwards introduced him into the Irish Parliament, as member for the borough from which he derived his title.

In the ordinary course of his political career by bold and sarcastic oratory, retaining himself almost entirely for great occasions. Hence his name is but little associated with the everyday business of legislation; the fame which he acquired in the Irish Parliament is principally connected with the seats which he opposed to the Whigs in the Irish Union in 1800. The vehement oratory with which he de- announced the ministry on this occasion, proved the means of increasing his professional engagements in the Irish courts of law. His exertions were rewarded with the chancellorship of the diocese of Ardfert in 1801. His professional honours were handsomely repaid, with liberal interest, the contributions of his father's congregation which had been the means of enabling him to get a start in life. About the same time he married Catherine, only daughter of John Macaulay, Esq., who had repre-

When the rebellion of 1798 broke out, Mr. Plunkett gave the aid of his professional talents to its victims, and indeed was at one time so intimate with Robert Emmett and his associates, that he was publicly accused of being concerned in their unhappy proceedings. The accusation however was shown to be unfounded.

In 1803 he was appointed solicitor-general for Ireland, from which post he was promoted in 1806 to that of attorney-general for the united provinces.

Wellington at their head, came into office, and he determined to throw in his lot with them. Accordingly he retained the attorney-generalship under their administration; whose well-known views offered an opportunity for the Catholic Association to press upon their notice the importance of granting Roman Catholic emancipation. Of this subject, Mr. Plunkett was always an able and energetic advocate. The death of Mr. Fox having broken up the Grenville administration in 1807, Mr. Plunkett, in the House of Commons, which he had once secured for him a high reputation, Mr. Canning affirmed, that it brought back the days of Burke and Pitt, of Fox and Sheridan. In 1822 a number of ministerial changes took place on the death of the Marquis of Londonderry, and Mr. Plunkett was appointed attorney-general for Ireland, the late Marquis of Wellesley being lord-lieutenant, and in that capacity he was engaged to prosecute on behalf of the crown a large number of the Dublin Orangemen, and some of the insurgents in the south of Ireland. Early in 1827 Mr. Canning proposed to appoint Mr. Plunkett master of the rolls in England, but the intention was ultimately abandoned. In the following June however he was elevated to the post of lord chief-justice of the common law courts of Ireland. On the death of Lord Donum. He held the chief-justice'ship for three years, and resigned it at the downfall of the Wellington administration. His judicial career was not marked by any great brilliancy or success, which indeed there were no remarkable or stirring events to call for, until it was removed, or the House of Lords, where he sat by the Duke of Wellington, at his Grace's special request, to advise with him at every step of the Roman Catholic Emancipation Bill, of which he 'took charge' in his passage through the Upper House.

With the passing of this measure the political career of Lord Plunkett may be said to have closed, though he was appointed Lord Chancellor of Ireland by the ministry of Earl Grey at the close of 1830. This post he occupied for eleven years, with the brief interval of a few months in 1834-36, during which the seals were held by Sir Edward Sugden (now Lord St. Leopards). He ultimately only resigned the chancellorship a few months before the removal of the Liberal administration of Lord Melbourne from office in 1844, when his place was immediately passed to Lord John Russell, in order to make way for Lord Campbell. During his later years Lord Plunkett had almost wholly retired from political life, and indeed for several years before his death he had not come over to England to take his seat in the House of Lords, but spent his declining days in the enjoyment of the society of his family and private friends, at his country villa near Bray, where he died on the 4th of January 1854. His eldest son, now second Lord Plunkett, is also Bishop of Tuam.

On the other hand he was bountiful to Lord Plunkett, and accident favoured him at almost every step of his long and brilliant career. He was sixty-six years of age when he took his seat in the Irish Court of Chancery, and it could scarcely be expected that his prospects would have been equal to his previous fame. His reputation shot upwards from a narrow ground-work. His speeches were at once few and famous;
they excited the unqualified applause of his contemporaries, and his name is still foremost among the orators of the 19th century. But the great principles of legislation, which men seek and find in the speeches of Pitt and Burke, are seldom met with in the startling orations of Lord Flunkett. His chief triumphs were as a lawyer and not as a statesman. He was an able and experienced practical politician; and there were able judges and more learned men than himself among his brethren on the Irish bench, though probably there were not so many of the more constructive eloquence.

POE, EDGAR ALLAN, was born at Baltimore, in the United States, in January 1811. He was descended of a good family, but his father and mother, who had become strolling players, having died when he was quite a child, he was brought up, after a while, by his maternal uncle, who had known his father, and having no children of his own, treated him as his son. In 1816 Mr. and Mrs. Allan brought him to England, where he was put to school at Stoke Newington. He returned to America in 1822, was first placed in an academy at Richmond, in Virginia, and thence sent to the university of Charlottesville in the same state. At all these places of instruction his progress was rapid, and he held a high rank as a scholar, but his extravagance was so great, and his conduct so licentious, that he was expelled from the university. He returned home, and on Mr. Allan refusing to honour some of his drafts for gambling debts incurred at the university, he wrote a satirical and abusive letter to his benefactor, left the house, and set off to Greece to make his fortune.

But Greece had never reached Greece, but after wandering about Europe for nearly a year, he arrived at St. Petersburg, fell into the hands of the police for a drunken riot, was rescued by the intervention of the minister of the United States, and by him sent back to America. Here he became the patron of such of his housemates as he liked, and as he now expressed a desire to adopt the military profession, he procured him the appointment of a cadet in the Military Academy at Westpoint in New York. Here, after a short period of academical application, his old habits returned, and within a twelvemonth he was cashiered for insubordination and drunkenness. He returned to Mr. Allan at Richmond, who again received him with kindness, but that gentleman having married a second wife, Poe satirized both him and his wife so severely that he was forced to quit that place of refuge, nor would Mr. Allan ever see him again or assist him any further. He had by this time published a small volume of poems, and from the favourable reception they had met with, he thought he might support himself by his pen. He failed, and enlisted as a private soldier. From this situation he was rescued by some military friends he had made at Westpoint, who procured his release. He again had recourse to his pen, and this time with more success. He contributed to various periodical works, with some as contributor, and with others as editor; but his irregular habits constantly prevented the engagements being permanent. He followed this course at Baltimore, Richmond, Philadelphia, and New York, where he arrived in 1844. His love of literature led him to think of his own employment, while his intemperate and immoral habits as necessarily occasioned his dismissal. In 1848 he gave a series of lectures in New York on the universe, which were afterwards embodied in a work entitled 'Eureka, a Prose Poem.' In the autumn of 1848 he joined a temperance society, but this could not save him. He went in 1849 to Virginia to deliver lectures, and on the 4th of October he set out on his return to New York. At Baltimore he met with some who inveighed against him as an intemperate man; and having failed to get his pledge, became so terribly intoxicated that he was picked up in the street, carried to a hospital, and died the following day, October 7th, 1849. His works, as may be supposed from the previous sketch, consist wholly of short pieces. He wanted the steadiness and perseverance to produce anything worthy of his genius; but they exhibit in a remarkable degree the possession of faculties of a high order. In his youth the magnificence of imagination and description — a remarkable faculty of anything that was waste upon trivial subjects; a love and an acute observation of nature, and an admiration of the beautiful, which it is remarkable in such a man never descends into the sensuous; combined with a gypsy and mystical sublimity in some of his fictions that is done by the most sublimity in some of his fictions that is done by the most

POLAND. The Emperor of Russia, by a ukase, dated August 25th, 1861, has ordered the Pacific Divisions, exclusive of the city of Warsaw, which are governed in the same manner as the other provinces of the empire, each having a military and a civil governor. The following table shows the area and population of the present divisions according to the official returns for the year 1866:

POLAR COUNTRIES AND SEAS. The countries and seas which lie between the northern coasts of America and the North Pole are noticed in the article North-West Passage, S. 2; those which are situated on the other sides of the North Pole are described under their respective names. [Greenland; Iceland; Spitzbergen; Nova Zembla; Spitsbergen; Nova Zembla, S. 18.

The seas which surround the North and South Poles are named the Arctic Ocean or North Polar Sea, and the Antarctic Ocean, or South Polar Sea. The two oceans are bounded by two imaginary circles which surround the globe at about 60° 90° N. lat. and 90° S. lat. Of the two oceans themselves there is only one day of six months, during which the sun never sets, and one night of six months, when the sun never rises. In the spaces comprised between the Polar Circles and the Poles the quality of continuous day and continuous night vary according to the distances from the Poles. Thus, at the north point of Nova Zembla, 75° N. lat., there is uninterrupted light from May 1st to August 12th, and uninterrupted darkness from November 8th to February 21st. At the Arctic Circle, the light is 24 hours at the summer solstice, and Midsommer's Day, whilst, at the same time, at the Antarctic Circle, the sun is 24 hours below the horizon; and the reverse at the opposite seasons of the year. The general coldness of the Polar Regions, as also of the Antarctic Circle, makes it necessary to produce anything that is done by the most sublimity in some of his fictions that is done by the most
senting an impassable barrier. On entering the Arctic Ocean from the Pacific through Behring's Strait, the most daring and skillful navigators have not been able to penetrate much farther in a northern direction than 70° N. lat. Captain Chastellain's ship, for instance, struck on the banks of the Strait, sailed as far westward as North Cape, 180° W. long.; but here the masses of ice prevented any farther advance. If the navigator, after passing through Behring's Strait, turns easterly, he will reach a passage, called the Bering Sea, and the pack-ice, a narrow passage, much encumbered with broken ice, and may thus with some difficulty reach the most north-eastern point of the American continent; or, having reached Bering Island, may turn northward and try to advanced along the coast of Asia. Passage by following either of the tracks of Captain McClure.

The great entrance to the Arctic Ocean by the Spitzbergen Sea is not attended with much difficulty. Ships sail every year from the shores of the Atlantic Ocean to the Spitzbergen Sea, and must necessarily pass round North Cape, 71° 10' N. lat.; other vessels proceed annually to fish for whales, which they never expect to take south of about 75° N. lat.; and others much smaller go every year from Hammerfest and other places to fish for walruses along the western shores of Spitzbergen. Barents, the Dutch navigator, in 1594 and 1596, traced the western shores of Nova Zembla as far as North Cape, 75° N. lat.; and the Russian navigator Ziwolks, who in 1536 surveyed the island of Nova Zembla, found no difficulty in passing through the eastern coast to 61° E. long.; but impenetrable masses of ice prevented his advance farther to the east.

The greater or less severity of cold in the Arctic Sea seems to be connected with the latitude or difference in degrees of latitude. Thus, on the European side of the Polar Basin, the navigation, as has been shown, is open as far as 80° N. lat.; on the Asiatic side it is generally closed by masses of ice; on the American side the cold is very severe, and the navigation is not possible. The ship's passage is most dangerous in the several sounds and bays, which are connected with the open sea by narrow passages, e.g., the Davis Strait, the Bering Sea, which is open to communication with the Pacific Ocean; the Fox and Lancaster sounds, which are connected with the Atlantic Ocean, the Spitzbergen Sea, and the Barents Sea; the Sound of Spitsbergen, which is connected with the North Pole, etc. For the coast of the Spitzbergen Sea is mad.

The enormous and constantly increasing ice-drift towards the North Pole, and the enormous and constantly increasing accumulation of ice in all the seas in the northern hemisphere, is the most terrible fact of the cold, that has been proved by the observations of Captain Barrow, and other navigators, that have passed through the北极, and been arrested by the ice. In the summer of 1859, the ice-drift was so strong that the ships were carried over the North Pole, and were stopped by the ice. In the summer of 1860, the ice-drift was so strong that the ships were carried over the North Pole, and were stopped by the ice. In the summer of 1861, the ice-drift was so strong that the ships were carried over the North Pole, and were stopped by the ice. In the summer of 1862, the ice-drift was so strong that the ships were carried over the North Pole, and were stopped by the ice. In the summer of 1863, the ice-drift was so strong that the ships were carried over the North Pole, and were stopped by the ice. In the summer of 1864, the ice-drift was so strong that the ships were carried over the North Pole, and were stopped by the ice.
Bourbon. "At last," says Polovoy in the autobiography prefixed to his 'Ocherki Russkoy Literatury', published in 1899, "I became my father's walking dictionary in geography and politics, and at that time I was never met with in anybody else. To learn by heart a whole tragedy cost me nothing. In a word, if I must describe my mental progress up to the year 1811, it was this: I had read about a third of the Russian authors, and remembered all that I read from the verses of Karamzin, and the articles in the 'Courrier de Europe' (a Russian Magazine), to the Chronological Tables and the Bible, from which I could repeat whole chapters by heart. I was known in the town of Kursk as the boy who made a collection of public laws. I was almost in constant movement from St. Petersburg to Irkutsk, and from Irkutsk to Irkutsk, and his literary ardour, deadened by the reproaches of his father, who now wished him to turn his head to another occupation, appeared as though it had been but but extinguished. It suddenly revived when he was about eighteen, a clerk at Kurk; but the main cause of its renewal, according to his own account, was his discontent with the then situation and its limited prospects, and his conviction that in Russia there was no other way to consideration for a person in his position but through learning and literary success. Himself and his younger brother, Xenophon, began to study French and German in secret, devoting many hours of the night to these two noblest of all the foreign languages, which he called his "so-called" languages, and this new world of reading, in 1817, when the Emperor Alexander paid a visit to Kurk, Polovoy sent to the 'Russian Courier' an article describing the event, and had the pleasure of seeing for the first time his name in print. Other contributions followed, and the name became known; on a visit to St. Petersburg he was introduced to Zhakovskoy, Gribiyedov, Grech, and Bulgari; and in 1820 he commenced at Moscow the publication of a magazine entitled the 'Moscow Telegram'.

For the twenty-one years that followed, Polovoy was in incessant literary activity. The 'Moscow Telegram' soon made itself conspicuous by the vigour and spirit of its remarks on the literature of the day; the example was extended by the more liberal Russian literary associations, and an era of new criticism in the articles of Polovoy and his friends naturally supposed that the editor had little spare time at his disposal, but the public was surprised to hear in 1829 that he had completed a history of the Russian nation, in 12 vols., containing a continuous narrative from the earliest times to the reign of the Emperor Nicholas. The early volumes of this history were assailed without mercy by many who were astonished at the presumption of its author in measuring himself with Karamzin, and of the twelve volumes only six appeared in print, the last in 1833. Possibly its further progress may have been checked by the censorship, as the 'Moscow Telegraph' was thought too liberal in its tendencies, and suppressed by the Russian government. This was in or about 1835. Polovoy removed to St. Petersburg, and his activity, instead of slackening, became greater than ever. In Moscow," says Nikitenko, in an article on his work in the 'Biblioteka dlya Chit'ennyaya' for 1848 (vol. xxvii.), 'Polovoy was a journalist, an historian, a romance-writer. In St. Petersburg, the man of all kinds of words, and contributions to several journals; he composed romances, tales, essays, translations from Shakspeare, and such a multitude of dramas, tragedies, comedies, vaudevilles, national fables, and so on, that no one attempted to follow him. We do not know what to most astonishing of all, the breadth of his knowledge, the range of his materials, the variety of their character, and the rapidity with which he threw them off.' The natural result of his rapidity was, that the name of Polovoy, which at one time promised to be one of the brightest in the Russian literary horizon, lost much of its lustre. For the last ten years of his life his reputation sank instead of rising. He died at St. Petersburg, on the 33rd of February 1848 (a. s.), after three weeks of fever, and was for a time neglected. His funeral was completely wrought by his incessant literary labours. He died in poor circumstances, and left a large family.

The most interesting work of Polovoy is perhaps his 'Ocherki Russkoy Literatury,' published in the 'Russian Literature,' 8 vols., St. Petersburg, 1839. It consists of reprints of select critical articles which had appeared in the 'Telegram' and elsewhere, on Devzhavin, Karamzin, Pushkin, and other of the most prominent names in Russian literature. It contains a fine collection of documents, of which the best is perhaps the statement of N. A. Polovoy ('Dramaticheskoe Sochenieniya i Perevody'), 4 vols., St. Petersburg, 1842-43, comprises only the more popular of his productions, several of which enjoyed a great success. In particular, the 'Grandfather of the Russian Fleet' ('Diedushka Russkogo Plota'), founded on the history of the old boat which bears that name, which Peter the Great took as the model for his ship-building. The author's favourite, as he tells us himself, was 'Parasha Siberichacka' ('Parasha the Siberian Girl'), founded on the same historical anecdote which supplied Madame Cottin with the groundwork of 'Elizabeth, or the Exiles of Siberia.' In another play, 'Boldatskasoe Ser'dce' ('A Soldier's Heart'), the hero is his still-living friend Bulgarin, on a real incident which occurred at Tula, during the war with Prussia, which was produced at Moscow in January 1837, is unusually close to Shakspeare; not even the scene of the gravediggers is omitted, and the dialogue passes from blank verse to prose, in such a manner that the two forms of versification are far from successful. His 'Life of Eurowor,' or Sowarrow, is a very popular book in Russia. His 'Life of Peter the Great' (4 vols., 1843), is the best biography of that wonderful man the Russians yet possess, and superior beyond all comparison to the tedious compilation of the author's kinsman Golikov. His 'Life of Napoleon' (6 vols.) was only brought by himself to a point a little beyond the confabulation of Moscow, and was finished after his death by his brother. By his own account, his 'Polevoy' ('The Wind of Russia'), or an historical picture of Russia from 1745 to 1845 (2 vols., 1840), is perhaps the least satisfactory of his historical works, but it contains passages of interest to a European reader.

Though the 'Moscow Telegraph' was suppressed in Polovoy's hands, and its author is spoken of by Hertzen as having the reputation of a decided liberal, his patriotism as a Russian is one of the qualities which most forcibly strike the attention of a foreigner. "Russias," he exhales at the beginning of one of his contributions, "is not a Roman empire, not violently put together like the dominions of Napoleon, not scattered over the whole world like the British sovereignty, the three examples of vast empires composed of different barbarous parts, brought together in one mass. . . . Russia like the ocean in which it stands, and what surrounds it, and what its waves have covered becomes its incontestable dominion—no human force shall tear from its subject provinces. "Assuming the title of Emperor in place of that of Tsar, moving the capital from Moscow to St. Petersburg, shaving beards and shortening caftans, altering manners, customs, and laws, it was after all from the original elements of the Russian empire, from the Russian mind and the Russian soil, that Peter the Great reconstituted Russia. He still remained a Russian sovereign, and his subject, though fraternizing with the German, remained a Russian man. With his decided tendencies towards western Europe, it was impossible that something superfluous should not find admirers, that this element should not remain till even now, but they are perishing and will perish, as the Gallicisms die out of our Russian tongue." . . . "And sixty millions of a nation like this, fastened together by one power and inspired with faith in that power, are directed by hundreds of ringleaders, and contributing in all as well as of Russia. Will not these sixty millions do! The future belongs to us. Whence otherwise comes the fear with which we inspire Europe and the West, the fear from which it strives to remove itself by calumnies against us. This fear takes rise from a numerous and very strong, which in the future, from a feeling different from that of hope in the future, on which we Russians look with such boldness and such faith." POLICE. The establishment of a police force all over England has at last been made compulsory by the Statutes.
POL 519

POL 19 and 30 Vict. c. 69; which subjects the whole force to the inspection, and, to some extent, control of the Secretary of State for War, and, in case of violation of the regulations, the police of any county or borough must be paid by the Treasury, when the force has been certified to have been maintained for the previous year in a state of efficiency in point of numbers and description. (Blackstone's Commentaries, 3d ed. i. 243.)

POLISHING SLATE. [Minerality, S. 1.]

POLPERO. [Cornwall.]

POLYERGUS, a genus of Formicidae, separated from Formica by Latreille. The type of the genus is F. rufescens, the Amazon Ant. These ants are destructive of stumps, and have the antennae near the mouth and the mandibles narrow, curved, or very much hooked. The habits of the Amazon Ant, F. rufescens, are very remarkable. The neuters of this species, as well as the males, are very much addicted to vinegar, and, when present, were always accompanied by the neuters of other species of Formicidae, especially C. curlicularia and F. fusca. The result of the conquest is the making slaves of the latter, who are always found doing the hard work of the colonies of their enslavers. [Avr.]

POLYPTERUS, a genus of Fishes belonging to the family Clupidae. The sides of the upper jaw are moveable; the head is covered with sharpened bony plates; the body with strong scales; it has one gill-ray; a number of separate fins on the tail; the eyes are on one side; it has a large mouth; a large double air-bladder, with large lobes, the left one opening freely into the gill-trough. There are two species; one found in the Nile, the other in the river of Azara, both of which can live several hours out of water. The living representatives of a large family now extinct. They belong to the large division of extinct fish called Sauroid, on account of their resemblance to the Lizard tribes.

POLYZOA, frequently termed Bryozoa, are animals belonging to the Molluscan Sub-Kingdom, and nearly allied in some respects with the Tunicata, and especially with the Compound Ascidians, whilst in others they approach the Brachiopoda.

The analogies presented in their structure with that in other Molluscan groups having been pointed out in the article Mollusca, S. 2, it will be needless here further to refer to them. The present article, after giving a brief view of the more important structural peculiarities of the class, will be devoted more especially to their mode of classification; but since the term Polyzoa, here employed, has by no means obtained universal adoption, it appears requisite to say a few words explanatory of the reasons which have induced us to prefer that term to the name Bryozoa, more usually employed by many British and by most Continental naturalists.

Section I. Historical.

Formerly confounded with the Suctarian and other phyla of the same order, it is only since the last thirty years that the Polyzoa have been admitted to their proper place in the animal kingdom, having been advanced in fact from one sub-kingdom to another. Their advance from the Radiata to the Molluscan may be said to date from the researches of Dr. Grant, contained in his Observations on the Structure and Nature of Flustra, in 1837; and of Milne-Edwards, in conjunction with M. Audouin, given in their Résumé des Recherches sur les Animaux sans Vertèbres fauteaux iles Chasséan, in 1838. To the former of these observers we are indebted for the first full intimation of the characters in any number of these creatures—among others, of the existence of ellia on the tentacles, and the curvature of the intestinal canal, with other particulars of less importance. He failed, however, to notice the existence of a second and oral orifice to the intestinal canal; a fact of the highest importance, as indicating in that respect their close approximation to the Arcidae, or tunicate molluses. This opening was discovered by Milne-Edwards and Audouin, and its importance vol. i. p. 303, and has ever since been daily appreciated. In other respects their observations agreed with those of Dr. Grant. The existence of this oral orifice was regarded by its discoverers as sufficient to justify a complete change in the idea of the animals under discussion, and to confer on them the affinities of these animals with the rest of the Zoophytes. They proposed to distribute the animals belonging to the class of Polypia, as then received, into four principal groups, which are in fact pretty nearly identical with those in which they are at present most generally placed. The fourth of these families contained the Flustra and other Polypia whose digestive canal opened on the exterior by two distinct openings, and whose organisation approached that of the Cephalopoda.

The latter class, though thus distinguished from its apparent allies, received no name from the eminent naturalists to whom its foundation was due; and of the names subsequently applied to it, it remains simply to determine which is entitled to have the preference. The Polypia was the name given by Mr. V. Thompson to this class of animals, which in all the specimens which have been examined under the name of Polypia hitherto in great measure confounded with the Hydroidea. This paper was published in December, and probably on the first of December, 1830. The appellation of Polypia by Audouin and Milne-Edwards, to those Polypia in which two openings existed to the digestive canal, and which he thus distinguished from a second class, termed by him the Anthozoa, in which but one orifice was presented. His paper on the Corals of the Red Sea, in which this subdivision of the Polypia was first proposed, was read, or rather was in part read, before the Berlin Academy, on the 3rd of March, 1831. It was not completed, however, till December, 1833, nor published until February, 1834; and this date, for reasons it is needless to enter into here, may be regarded as the true date of its publication. The part of the same writer's 'Symbole Physique,' in which the term is used, was not published till June, 1831. Consequently, the earliest date of discharge of any work in which the term Polypia is used is the first publication of the term Bryozoa, in March, 1831, or at least three months after that of Mr. J. V. Thompson's 'Researches,' in which that of Polypia is proposed. In a very valuable paper published in the Philosophical Transactions for 1834, Dr. A. Fraser proposed the term Oolithoideas for this class of Polypia, from the circumstance that their tentacles are ciliated. But this term, though appropriate and good, has since been but rarely employed, and is obviously without any claim to priority.

Section II. Structure and Functions.

The main points in the anatomy and structural relations of the Polyzoa will be found under the article Mollusca, S. 2; but in order to render the account of their classification (which is properly the subject of the present article) more intelligible, it will be necessary briefly to detail the structural, and with them some of the physiological conditions presented in the soft parts of these animals.

The Polyzoa may be defined as Compound Molluscan Animals, in which the nervous system consists of a single ganglion, situated between the mouth and the anus, having a distinct mouth surrounded more or less completely by a row of tentacles or cirri, which can be extended or retracted by buds or ovaries; in the mature state mostly fixed, though some possess the power of locomotion.

Though differing widely in external appearance, the animal itself is constructed upon a very uniform type throughout all the subdivisions of the class, and for this reason, the anatomy of some species or order will, with trifling exceptions, apply to all. The following account of their structure is, in great measure, taken from that given by Professor Allman in his Report on the Freshwater Polyzoa, published in the Proceedings of the British Association 'for 1830; and, with the exception of the word 'polyzoary,' or 'polyzoarium,' which is here used to express the compound growth formed by the associated animals, instead of 'caecumium,' proposed by that naturalist, the terms used by him have been adopted—

1. Polypia, to signify the soft or retractile portion of the Polyzoa. 2. Ectocyst and Endocyst, to express the two distinct surfaces of which the cells of the polyzoa are formed; and from the former, the external, to the latter, the internal. 3. Three or the exception of the word 'polyzoary,' or 'polyzoarium,' which is here used to express the compound growth formed by the associated animals, instead of 'caecumium,' proposed by that naturalist, the terms used by him have been adopted—

3. Polypia, to signify the soft or retractile portion of the Polyzoa. 2. Ectocyst and Endocyst, to express the two distinct surfaces of which the cells of the polyzoa are formed; and from the former, the external, to the latter, the internal. 3. Three

POL

Mouth, or that opening, as it may be termed, through which the polypide makes its exit and its entrance. The borders of this opening are sometimes furnished with Oral Spines, and it is sometimes closed when the creature has retreated into the cell, by a Crescentic Lip, usually having a cartilaginous border, and secreted by special muscles. (Figs. 5 and 6, &c.)

In many cases the wall of the cell is of equal thickness and similar structure throughout, but in the Cheldestomata sub-order the front of the cell, or that side upon which the mouth opens and the animal comes out, very often differs from the rest. That is to say, a greater or less extent of the front may remain wholly or in great measure membranaceous, as in the genus Membranipora (fig. 14); or it be filled in by a sculptured or perforated calcareous expansion, as in Catenicula (fig. 1, b), Lepora (fig. 1, a), &c. The former constitutes a sort of inflated mantle or the other kind of a long, slender, moveable seta. However diverse in appearance, these two kinds of organs are all constructed upon the same general type; that is to say, the organ consists of a hollow stem, or cell, containing two sorts of muscles, for the movements of the mobile limb, the mandible, as it is termed, in the one case, and the seta in the other. The avicularia again are either pedunculate and moveable upon the peduncle, or sessile, which latter may be either simply sessile or deeply imbedded. The former is a sort of an arched or globose or pyriform shape found on many of the Chelostomata and on some of the Cyclotomata, apparently destined for the development of ova. In the former class it is invariably situated above the mouth; and in the latter the analogous organ seems to represent a metamorphosed cell, and in situation corresponds with the other cells of the polypide.

The importance of the avicularia and the visceral organs, in a systematic point of view, may be estimated from the circumstance that, out of 36 genera of Chelostomatous Polyzoa, 26 include species armed with one of the other, or with both; and that of 101 species no less than 128 are furnished with both. They appear to be confined solely to the Chelostomata.

In many cases the polypide is lined by numerous alenader corneous tubes, which seem to be merely subservient to that purpose; these are termed Radical Tubes.

The species itself is an aggregation of an aggregation of cells, which throughout the two former orders of the class as here arranged, arise one from another, either singly or in pairs, from each cell (fig. 15a, which represents the beginning of the polypide of Lepora cidilus), and from various parts of the cell, on the back or sides, near the top or not far from the bottom. And it is to the variety of modes in which the cells arise that the diversity of form of the polypide is due. In one division of the third sub-order, the Cheldestomata, the cells do not arise from another, but from a tube common to several cells, and which is either divided or not into distinct intermedes. This portion of the polypide is termed the Basal Tube.

Having thus defined most of the terms which it is necessary to employ for the purposes of classification, we will briefly describe the anatomy of the various parts of the animal in the order in which it is given by Professor Allman.

Organs for the Preservation of the Individual.

A. Dermal System.

The Polypide is formed of a number of little chambers, or cells, organically united, each of which contains a polypide, and is limited by two walls, a firm, tough, membranaceous, and contractile (the Endocyst), and an external investment (the Ectocyst). The endocyst lines the interior of the cells and when it arrives at its orifice would protrude beyond the ectocyst, were it not that here it becomes invaginated, or inverted into itself, and then terminates by becoming attached round the base of the tentacular crown; during the exfoliation of the polypide it undergoes eversion, sometimes complete, sometimes incomplete. The former constitutes a sort of hollow chamber, in which the polypide is suspended, surrounded by the perigastic space. These sacs are all closed above where they are attached to the polypide, and below, in some cases, their cavities are in communication with those of the neighbouring sacs (or with the lophophore). In such cases, it is clear, that order exists.

The endocyst and ectocyst represent respectively the external and middle tubicula of the Tusciato, or the mantle and shell of other Moluscas.

The endocyst is in all cases thin and membranaceous, and therefore containing only muscular fibres. A portion, perhaps the whole, of the inner surface is clothed with vibratile cilia.

The endocyst varies greatly in composition and aspect. Throughout the greater number of the Polyzoa it is hardened by the deposition of calcareous matter, whilst in many others it is horny and flexible, and in some even of an almost gelatinous consistence. In the P. Hippocrepia it is in most species composed of a tough perigastematic brown membrane, strengthened by the deposition of irregularly formed calcareous matter, sometimes rendering it quite opaque. In other cases again, as in the genus Argulina v. Ben., the soft and flexible, and as it were floculent ectocyst, is pervaded by aluminous and siliceous particles, and the same is the case, as a more extended examination of the Chelostomata, as in Oritractia, Peliceilla the ectocyst would, at first sight, seem to be entirely absent, and the cell to be composed exclusively of the endocyst. Careful examination however shows that both are present, and that the ectocyst, or more accurately, the lophophore, not being free from any earthy deposit. In some instances, and very distinctly in the Selonariadae, or Lunalites, the surface of the calcareous ectocyst is further covered with a thin horn cuticle, apparently resembling that on the shells of many Moluscas.

B. Organs of Digestion.

These consist of an alimentary canal, commencing at the mouth and terminating at the anus; and are subdivided into several portions, which have received the same names as those of the apparently corresponding parts of the alimentary tract in the higher animals. The mouth is edentulous and usually unarmed, though sometimes (as in the proper P. Hippocrepia) furnished with a valve-like organ of very peculiar formation, and which is considered by Professor Allman to be analogous with the 'tongue' of the Ascidians.

From the mouth an oesophagus, or pharynx, leads downwards into the stomach, which in some cases is confined into a sort of gizzard, which in that genus is armed on each side with a serrated tooth. The stomach is a thick walled sac, in most cases dilates inferiorly into a rounded cul-de-sac, or pyloric cavity, from which the intestine springs. The intestines are usually distinguished from the stomach by prominent lips, which project into the intestine. The intestine, wide at the origin, rapidly diminishes in diameter till it terminates at a distinct anus near the mouth. The liver is represented by spherical corporcles of a brown colour, seated on the wall of the stomach. The mouth and upper part of the oesophagus and the commencement of the intestines, are, in most cases, at any rate, furnished with vibratile cilia.

C. Organs of Respiration and Circulation.

Upon the tentacular crown and the walls of the perigastic space, which corresponds with the 'sinus system' of the Tunicata, would seem chiefly to devolve the function of bringing under the influence of the arterial medium the nutritive fluid of the tissues.

The tentacular crown of a Polyzoan consists of two portions; 1. a sort of siage, or disc, which surrounds the mouth and terminal view; and 2. trees, which are borne in an uninterrupted series round the margin of the lophophore. The lophophore throughout almost the entire class is orbicular or annular; but in the Hippocrepia its posterior margin, or that which corresponds to the rectum, is conical, and in the other species so shrunken that that order it exhibits the form of a deep cresent. This condition of the lophophore is found in no marine species, and in Pedicellina, a fresh-water form, the arms of the
a wide of their and probably the would bat if an POL destitute is observed. filaments and Allman been demonstrated, in a series a regular, and vibrating towards the extremity of the tentacle upon one side and towards the base by means of a very irregular form and size. This fluid obviously represents the blood or common nutrient and respiratory fluid of other Molluscs. It is kept in motion by the cilia with the downwards along the membrane connecting the bases of the tentacles of the P. hippocrepia.

The perisarcic space and the interior of the lophophore and tentacles all freely communicate with one another, and are surrounded by the base of a mass of a very irregular form and size. These fluidic masses resemble the blood or common nutrient and respiratory fluid of other Molluscs. It is kept in motion by the cilia with the downwards along the membrane connecting the bases of the tentacles of the P. hippocrepia.

The perisarcic space and the interior of the lophophore and tentacles all freely communicate with one another, and are surrounded by the bases of a mass of a very irregular form and size. These fluidic masses resemble the blood or common nutrient and respiratory fluid of other Molluscs. It is kept in motion by the cilia with the downwards along the membrane connecting the bases of the tentacles of the P. hippocrepia.

D. Organs of Motion

The muscular system in the Polypoecos is highly developed, and the muscles are arranged so as to exhibit interest in a physiological point of view, for they seem to present an example of true muscular tissie reduced to its simplest and essential form. They are composed of bundles of elementary fibres, each being in length, and which are distinctly marked with transverse strie. They resemble in fact very closely the fibres of the thoracic muscles of insects. In the marine Polypoecos however another kind of fibres may be noticed, presenting nodular enlargements, which would seem to resemble very closely the isolated, organic muscular fibres of the higher animals. The muscles are disposed in distinct sets, and it is by the agency of these various sets that the movements of propulsion and retraction of the polypide are affected, together with the actions of the tentacles and of the avicularia and vibracula. For the arrangement of the muscles in the former class of organs see fig. 2 (6), in the article MOLLUSCA, p. 2. The curious analogies in the disposition of these muscles in the Polypoecos with that of each other, the lined but there is no special circulatory organ as in the Annelid.

E. Organs of Sensation

A distinct nervous system was first shown to exist in the Polypoecos by M. Dumortier in Lophopus crystallinus, and has been demonstrated by Van Beneden in Lamignula, and by Allman in all the Hippocrepian genera except Paludiceula; it may be deemed therefore to exist generally in the class, and that the forms which are devoid of it, are exceptions. It is possible that the species of the Hippocrepian order may there be seen, attached to the external surface of the osophagus, on its rectal aspect, just below the mouth, a hollow oval body of a yellowish colour, which is undoubtedly a nervous ganglion, as Professor Allman has succeeded in distinctly observing nervous filaments in connection with it; some of which may be traced going to each tentacle. The ganglion also sends off filaments upwards towards the mouth, and one may be induced to think that the lining of the tentacle is composed of nothing like a complete collar surrounding the tube has been observed.

The Polypoecos do not seem to possess any special organs of sense.

F. Organs of Locomotion

In Cristatella, the ectocyst, according to Professor Allman, in highly contrac tile, and presents, below, a flattened disc, destitute of apertures. Upon this disc, which closely resembles the foot of a Gasteropod, the singular polymeric cymes about upon the stems and leaves of aquatic plants. Except in the embryonic condition no other Polypoecos would seem to possess any power of locomotion; or at any rate none has been noticed, but several reasons would seem to render it improbable that the ones belonging to the Solenostome may be capable of locomotion by means of their curiously constructed vibracula.

G. Reproduction

In the Polypoecos, observes Professor Allman, three distinct modes of reproduction may be taken into account; namely, by eggs or germ; by true ova; and by free locomotive embryos.

1. Reproduction by Eggs.—The eggs always originate in the endocyst, first appearing as small tubercles projecting into the perisarcic space, but which may soon be seen to be enveloped in a membranous covering. If the bud now presents the appearance of a vesicle projecting from the exterior of the parent-cell, closed at its external or free extremity, but having its cavity in communication with the perisarcic space. The position is gradually developed in the interior of the egg by the differentiation of its fine granular contents, and the extremity of the bud ultimately opens so as to admit of the excretion and retraction of the young animal. Thus is produced a fresh cell of the polyzoal form, as a free zygote, whose exit depends upon the point of the cell at which the bud springs. This differs in almost every species, and upon this difference depends the diverse physiognomy of the various species. For instance, if each cell pullulates at a single point at the upper or lower extremity of the vesicle, and should be presented; if from each cell two are given off and remain in close apposition, a circularly expanded disc of greater or less regularity is developed, the extremity of this disc depends upon the point of the cell at which the bud springs. In the Polypoecos, Professor Allman says, that the ovary and testicles are both found in the same cell. The former is an irregularly shaped body, adherent to the inner surface of the endocyst, towards the upper part of the cell. The testicle is an irregularly lobed mass attached, like the ovary, to the inner surface of the endocyst. It occupies a position near the bottom of the cell, and is thus separated by a wide interval from the ovary. The ovary is at the side of the stomach by a cylindrical cord. The form of the ovary in the proper Hippocrepia would appear more to resemble a moniliform cord. In Laguncula (Farrella), according to Van Beneden, the ovary and testicles, in form and situation, would seem very closely to resemble those in Polypoecos (figs. 15 and 16). some Membranopora, &c., and so on.

2. Reproduction by Ova.—All the fresh-water, and probably, also, all the marine Polypoecos, produce true ova, which are formed in a definite organ or ovary; and from the case of the ova differing in different species, we are led to expect the co-existence of a male organ. That a testis is present in all the species of fresh-water Polypoecos, at any rate, no doubt, according to Professor Allman, can be entertained, and in Laguncula (Farrella) is in the existence of the ovary. This organ is described and figured by Van Beneden. In Paludiceula Professor Allman says, that the ovary and testicles are both found in the same cell. The former is an irregularly shaped body, adherent to the inner surface of the endocyst, towards the upper part of the cell. The testicle is an irregularly lobed mass attached, like the ovary, to the inner surface of the endocyst. It occupies a position near the bottom of the cell, and is thus separated by a wide interval from the ovary. The ovary is at the side of the stomach by a cylindrical cord. The form of the ovary in the proper Hippocrepia would appear more to resemble a moniliform cord. In Laguncula (Farrella), according to Van Beneden, the ovary and testicles, in form and situation, would seem very closely to resemble those in Paludiceula. It would appear also that the impregnation of the ova is effected by their escaping from the ovary into the perisarcic cavity, where they are brought into contact with the spermatzoa, which have in like manner escaped from the testicle into the same cavity, and are swimming actively about in vast numbers in the fluid with which it is occupied. There does not appear to be any special opening for the escape of the ova after impregnation, which is probably effected by the fluid from the endocyst. The forms of the ova vary a good deal in different genera, and in some cases they are ciliated.

3. Professor Allman also describes a mode of reproduction by free embryos, but does not seem to have noticed their mode or plan of development, consisting of coelomal development. The embryo upon its escape from the ovum appears sometimes to be ciliated, sometimes not. In the case of Lepralia coccineus, a chellostomatous species, the appearance of an embryo of the Polypoecos of recent development are well described by Mr. Ooss (Naturalist's Rambles on the Devonshire Coast, p. 218). But although the above brief description of the reproduction of the Polypoecos by ova formed and impregnated within the perisarcic space, and afterwards extruded, is undoubtedly correct, it is only to the species in which it has actually been observed, but from analogy to others as well, it cannot be denied that very considerable obscurity rests upon the mode in which the ova are developed in the ovicells or receptacles, which have
received that name, and as to the relation which those organs bear to the rest of the animal. There can be no doubt that these organs contain an ovum or ova, and that these ova are developed from, in them, and there undergo segmentation; but how these ova are fertilised, and why a difference so great as this in the position of the ovivorous organ should exist in apparently closely allied genera or even species, is at present inscrutable.

Section III. Classification.

The more general relations of the Polyzoa having, as before observed, been described under the head of Motisia, the remainder of this article will be devoted to the mode in which they may be conveniently arranged among themselves.

With our present defective knowledge of many particulars respecting the conformation of the Polyzoidea, the classification of the Polyzoa can only be attempted with any prospect of useful results, from the study of the Polyzoa; that is to say, so far as regards the determination of the subordinate groups—the orders themselves being defined by characters derived from the Polyzoidea, or soft portion of the animal. The following scheme, which in its main features has been long received, appears to offer as convenient, and so far as our present acquaintance with the subject allows, perhaps as natural a classification as can be expected.

Class Polyzoa.

Social molluscan animals, whose nervous system consists of a single post-esophageal ganglion, with branches, but without a nervous ring around the esophagus; and without any special organs of sense or of circulation. Mouth surrounded more or less completely with a single row of ciliated tentacles.

Bryozoa, Ehrenb., 'Corallien-Thiere des Roth. Meere,' 1831 (1834 i).

Mollusca Zoophyta, see Zoophyta Ascidioidea, Johnston, 'Mag. Zool. and Bot.', 1836.

Ciliobrachia, Farre, 'Phil. Trans.,' 1837.

Order I. Polyzoa incommunulata, Gervais.

Tentacles disposed on an uninterrupted annular lophophore, surrounding the unarmed mouth.

Sub-Order I. Chelomastata.

The crescentic subterminal mouth of the cell is furnished with a moveable lip, by which it is closed when the animal retreats.

Escharidae, Plumatidae, Cellariidae (ex. Orissa), Fleming. Polyopariara operculifera et cecumopicus (ex. Orissa), Blainville.

Escharana, Cellagoria, Ehrenberg.

Urococellata (pars), Hapagow.

A. Cells disposed in a single series.

Family 1. Catenicellidae, Bok.

Cells connected by short flexible tubes.

Gen. 1. Catenicella, Blainv. (Figs. 1, 2.)

Cells connected by short corneous tubes, all facing the same way; polyzoan pharynx, erect, dichotomously branched; cell at the bifurcation geminated.

a. Peristrepta. Cells fenestrated in front; ovicella terminal. beta. Vittata. Cells with a narrow elongated band or vittae on each side in front; ovicella galleriform, not terminal.

Catenicella, Blainville; 'Brit. Mus. Cat.,' p. 3.

Catenaria, Savy, 'Egypt,' pl. 13.

About seventeen species known; mostly Australian.

Gen. 2. Alysium, Bok.

Three species known.

Gen. 3. Calpodium, Bok. (Fig. 3.)

Cells with an avicularium on each side; each cell with three distinct apertures, arising one from the upper part of another in a linear series, connected by short corneous tubes.
B. Cells disposed in a double or in multiple series.

Family 3. *Salicornariadae.*
Cells disposed around an imaginary axis, forming cylindrical branches of a dichotomously divided erect polyzoary.
- *Salicornaria* Gray.
*Salicornaria* (pars), Brit. Mus. Cat., p. 15.

Gen. 1. *Salicornaria,* Cuvier. (Fig. 4.)

Front of each cell much depressed, surrounded by an elevated ridge, by which the surface of the branch is divided into more or less regular, rhomboidal or hexagonal spaces; avicularia scattered; oviscells immersed, inconspicuous; branches articulated.

*Salicornaria,* Cuvier; Johnston; 'Brit. Mus. Cat.', p. 15.

*Paracellaria* (pars), Gray; Johnston, 'Ed.' i.

*Cellaria* (pars), Lamark; *Linn.: De Blainville.*

Five species.

Gen. 2. *Nellia,* Busk.

*Front of cell convex, with a distinct raised border; aperture very large; oviscells (?) no avicularia.

*Salicornaria* (pars), Busk; 'Voyage of Rattlesnake,' i. 367.

Two species.

Gen. 3. *Vincularia,* De Blainv. (Fig. 19.)

Polyzoary rigid, calcareous, inarticulated; surface not areolate; aperture large; no avicularia; oviscells inconspicuous.

*Glacolumna,* Goldfuss.

*Stiphanella,* Hagenow.

*Cellaria,* (pars), Reuss.

One recent species; numerous fossils.

Gen. 4. *Pareiminaria,* Busk. (Fig. 5.)

Polyzoary cornose, flexible; margin of aperture much raised; aperture very large; oviscells encuillate, prominent; no avicularia.

*Pareiminaria,* Brit. Mus. Cat., p. 32.

One species.

Cells disposed in the same plane, forming linear branches of a dichotomously divided phytoid, erect, articulated polyzoary.

*Bugulida* (pars), Gray.

*Cellulariada* (pars), Johnston.

*Escharida* (pars), Johnston; Gray.

Gen. 1. *Cellularia,* Pallas. (Fig. 5.)

Cells bi-triarial; more than four in each internode; oblong or rhomboidal, contiguous; perforated behind, unarmed, or very rarely with an avicularium on the upper and outer angle of the cells.

*Cellularia* (pars), Pallas; Fleming; Johnston (pars);

*Bugula* (pars), Gray; Oken.

Three species.

Gen. 2. *Menipea,* Lamouroux.

Cells oblong, or elongated and attenuated downwards; imperforate behind, with a sessile avicularium (frequently absent) on the upper and outer angle, and one or more sessile avicularia on the front of the cell below the aperture (not always present).

*Cellaria* (pars), Linn.; Solander.

*Cuvia* (pars), Lamouroux.

*Triellaria,* Fleming; Blainville.

Six species.

Cells rhomboidal, with a sinus on the outer and hinder aspect; each furnished with a sessile avicularium at the upper and outer angles, and with a vibraculum behind. Cells basiolar and numerous in each internode.

*Scrupocellaria,* Van Beneden; Gray; 'Brit. Mus. Cat.,' p. 23.

*Biedellaria* (pars), Blainville.

*Cellularia* (pars), Pallas; Johnston.

*Cellaria* (pars), Solander; Lamark.

*Scrupusulata* (pars), Oken.

Seven species.

Gen. 4. *Canda,* Lamouroux.

Cells rhomboidal, situated on the outer side for the lodgment of a vibraculum; no avicularium on the upper and outer angles; sometimes one in front of the cell.

*Caudara* (pars), Lamark.

*Cellaria* (pars), Van Beneden.

*Biedellaria* (pars), Blainville.

*Scrupocellaria,* Gray.

*Celliculata* (pars), Johnston.

Two species.

Gen. 5. *Emma,* Gray.

Cells in pairs or triplets; a sessile avicularium (sometimes wanting) on the outer side below the level of the aperture.

*Emma,* Gray; 'Brit. Mus. Cat.,' p. 27.

Two species.

Family 5. *Cabereuda,* Busk.

Polyzoary dichotomously divided into ligulate bi-multiserial branches; on the backs of which are vibracula, each of which is common to several cells.
Cells bi-multiserial, in the latter case quincuncial. Back of branches covered with large vibracula, which are placed obliquely in two rows, diverging in an upward direction from the middle line, at which the vibracula of either side do not meet with those of the other.

(Fig. 10.)

Gen. 2. Anomastis, Busk.

Cells bi-quadrisserial; vibracula small, resembling avicularia.

One species.  

No vibracula; avicularia, when present, pedunculate.

Bicellariidae, Busk; 'Voyage of Rattlesnake.'

Bicellaria, Gray.

Gen. 2. Halophila, Gray.

Cells contiguous, attenuated downwards; much expanded above, with a large plain aperture unarmed.

Halophila Gray; 'Dief. New Zealand; 'Brit. Mus. Cat.', p. 43.

Bicellaria, Busk; 'Voyage of Rattlesnake.'

Gen. 3. Bugula, Oken.

Cells elliptical (behind), closely contiguous, bi-multiserial; aperture very large; margin simple, not thickened.

Bugula, Oken; Gray; 'Brit. Mus. Cat.', p. 43.

Acaamarchia, Lamx.; Blainville.

Crista (ep.), Lamx.

Cellaria (ep.), Lamarck.

Cellularia (sp.), Fleming; Johnston.

Four species.

Gen. 2. Gemellaria, Savigny.  
(Fig. 29.)

Cells opposite in pairs. Polysanary continuous.

Gemellaria, Savigny; Van Beneden; Johnston; Gray; 'Brit. Mus. Cat.', p. 34.

Gemicellularia, Blainville.

Loricaria, Lamx.

Notamia (pars), Fleming.

Loricula, Cuvier.

Crista (sp.), Lamx.; Lamarck.

Serpoptera (L), Oken.

One species.

Cells joined side to side; no avicularia.

Didymia, Busk; 'Voyage of Rattlesnake; 'Brit. Mus. Cat.', p. 35.

One species.

Gen. 3. Dimotopia, Busk.  
(Fig. 9.)

Cells joined back to back; aperture oblique; each alternate pair of cells looking the same way.

Dimotopia, Busk; 'Voyage of Rattlesnake.'

Two species.

A pair of tobacco-pipe shaped avicularia, visible above each pair of cells.

Epistoma (sp.), Fleming; Gray.

Dynamena (sp.), Lamx.; Blainville.

Gemicellularia (ep.), Blainville.
Sertularia (sp.), Gmelin.
Cellularia (sp.), Pallas.
One species.

Family 8. Fluistradae, Gray.
Polyzoa flexible, expanded, foliaceous, erect; sometimes decumbent and loosely attached. Cells multiseriate, quinquecunial, or irregular.

Fluistrada, Linn.; Johnston (pars).
Fluistradae, Gray (pars); 'Brit. Mus. Cat.', p. 48.
Escharidae (pars), Johnston; Gray.
Polyplacata (pars), Lamarck.

Gen. 1. Fluistrada, Linnæus.
Cells contiguous; on both sides of the frond.

Gen. 2. Carbaseae, Gray. (Fig. 12.)
Cells contiguous; on one side only of the frond.
Carbaseae, Gray; 'Brit. Mus. Cat.', p. 60.
Ten species.

Gen. 3. Diachoria, Busk. (Fig. 13.)
Cells disjunct; each connected with six others by tabular processes.

Diachoria, Busk; 'Voyage of Rattlesnake.'
Three species.

16a. Young state of Lepralia ciliata.

Family 9. Membraniporidae, Busk.
Polyzoa membranaceo-calcareous, or calcareae, expanded, encrusting (sometimes foliaceous, contorted, and sub-erect). Cells horizontal, quinqueunial, or serial.

Membranipora, Gray; p. 48.

Polyzoa encrusting (or suberect, foliaceous, and contorted), spreading irregularly. Cells more or less irregularly disposed or quinquecunial, with raised margins; a greater or less extent of the aperture occupied by a thin membrane.

Gen. 1. Membranipora, Johnston. (Fig. 14.)

Polyzoa encrusting (or suberect, foliaceous, and contorted), spreading irregularly. Cells more or less irregularly disposed or quinquecunial, with raised margins; a greater or less extent of the aperture occupied by a thin membrane.

Eschara (pars), Pallas.
Fluistrada (sp.), Linn.; Esper; Berkeley; Lamarck; Grant; Fleming; Risso; Johnston; Lamaroux.

Annulipora, Conopeum, Callopora, Amphiabatium, Micropora, Gray.

Eighteen species.

** Aperture of cells entirely filled in by a convex calcareae expansion. Cells disposed in more or less regularly radiating lines.

Gen. 2. Lepralia, Johnston. (Figs. 15 & 15a.)

Polyzoa encrusting, craspeaceae, spreading from a centre in a more or less circular form; composed of contiguous, or connected, calcareae, decumbent cells, the wall of which is complete in front.

Lepalia (sp.), Moll.; Pallas.
Lepalia, Johnston; Gray; 'Brit. Mus. Cat.', p. 63.
Berenicea, Fleming (non Lamaroux nor Peron).
Escharina (sp.), Milne-Edwards; Gray.
Escharidae (sp.), Milne-Edwards.
Cellepora (sp.), Oken; Audouin (pars); Lamaroux (pars); Hagenow (pars).
Fluistrada (varior).
Discopora, Lamarck (pars); Gray (pars); Lamaroux (pars).

Orbillo, Herencia, Escharilla, Porela, Celleporella (all sps.), Gray.

1. Armatae. Species provided with either avicularia or vibracula.

A. Species having avicularia.

a. Median and single.

* Superior (above the mouth).

** Inferior (below the mouth).

b. Avicularia double, or azygous and lateral on each cell, or only on some cells in the polyzoa.

B. Species having vibracula.

2. Inarmatae. Species without either avicularia or vibracula.

a. With oral spines.

b. Mouth unarmed.

About fifty or sixty species.

Family 10. Celleporeida, Busk.
Polyzoa or acoenous, composed of cells, standing more or less

P 0 L

525

P 0 L
vertical to its axis or plane, heaped together, or irregularly overlapping each other.

**Celleporidae**, Johnston (pars); 'Brit. Mus. Cat.', p. 89.

Gen. 1. *Cellepora*, O. Fabricius. (Fig. 16.)

*Cellepora* calcareous, rigid, adnate or erect, composed of urceolate, suberect, contiguous cells, heaped together irregularly, or arranged quincuncially. An ascending rostrum on one or both sides of the month usually furnished with an avicularium.

*Cellepora* (sp.), O. Fabricius; Johnston; Linnæus; Müller; Berkeley; Stewart; Lamark; Lamouroux; Fleming; Olivi.

**Echihara** (pars.), Oken.

**Millepora** (pars.), Linn.

**Millepora** (pars.), Pallas; Ellis and Solander (pars).

**Eschara** (pars.), Pallas.

* Adnate, globose, or spreading.
** Erect.

Eight species.

Polyzoa erect, rigid, foliose and expanded, lobate or reticulate. Cells disposed quincuncially in the same plane, on one or both surfaces.

**Escheridae** (pars.), Johnston.

*Lepralianus* (pars.), Gray.

**Retepora**, Gray.

Gen. 1. *Eschara*, Ray. (Fig. 17.)

Polyzoa foliose and expanded, or contorted, or branched and sublinear. Cells disposed on both surfaces, back to back, immersed, coalescent, horizontal to the plane of the axis.

**Eschara**, Ray; Fleming; Johnston; Lamark; Gray; Pallas (pars); Moll (pars); 'Brit. Mus. Cat.', p. 89.

**Nullipora** (pars.), Solander.

**Cellepora** (sp.), Esper.

* Polyzoa more or less expanded, foliose.
** Polyzoa subdivided into branching lobes.

Eleven species.

Gen. 2. *Retepora*, Imperato. (Fig. 29.)

Polyzoa foliose, calcareous, reticulated. Cells immersed, opening at one surface only.

**Millepora**, Linn. (pars); Ellis and Solander; Esper; Marsigli; Cuvier.

**Retepora**, Imperato; Lamark; Risso; Fleming; Stark; De Blainville; Couch; Johnston; Goldfuss (pars); Hagenow (pars); 'Brit. Mus. Cat.', p. 93.

**Frenchiopora**, Oken; De Blainville.

Three species.

**Fig. 18; vide also fig. in Cellebrma.**

Each cell throughout the polyzoa with a vibraculum at the summit.

*Cupularia*, Lamouroux (proposed); 'Brit. Mus. Cat.', p. 97.

**Lamellites**, Lamouroux (pars); Defrance (pars); Des- longchamps (pars); Goldfuss (pars); De Blainville (pars); Gray; Cuvier and Brongniart; Lonsdale (pars); Michelin (pars).

**Frenchiopora**, Lonsdale.

Five species (recent); numerous fossil.

Cells arranged in series radiating from the centre and bifurcating as they advance; vibracula in linear series alternate with those of the cells.

As in the preceding species.

Four species (recent); numerous fossil.

Polyzoa more or less regularly orbicular, convex on one side, plane or concave on the other (probably free). Furnished with large and powerful vibracula, with variously formed sets (probably locomotive).

Polyzoa more or less regularly orbicular, convex on one side, plane or concave on the other (probably free). Furnished with large and powerful vibracula, with variously

Polyzoa more or less regularly orbicular, convex on one side, plane or concave on the other (probably free). Furnished with large and powerful vibracula, with variously formed sets (probably locomotive).

Pol.

Sub-Order II. Cyclostomatata.

Cells tubular, calcareous, immersed or exerted; mouth terminal, without any moveable appendage or lip.

Tubulipora, Milne-Edwards.
Tubuliporides, Johnston.
Auloporina (pars), Ehrenberg; Johnston.

A. Erecta.
Polyzoary erect, free, simple or branched, linear or expanded above; branches articulated or continuous.

Polyzoarium divided into distinct internodes, connected by a horny substance.

Sertularia (pars), Linn.; Berkeley (pars); Esper (pars); Cellularia (pars), Pallas; Hogg.
Cellaria, Ellis and Solander (pars); Lamarck (pars).
Sertularia, Lamouroux (pars); Risco (pars); Fleming (pars); Templeton.
Uncularia (pars), Blainville.
Crinidea, Milne-Edwards.
Crista (pars), Johnston; Hassall (pars), &c.
One or two species.

Gen. 2. Critia, Lamouroux.
Two or more cells in each internode.
Syn. as above.
Three species recent; several fossil.

B. Adnata, a. decumbentes.
Polyzoarium adnate or suberect above, decumbent and adnate below.

Family 3. Tubuliporacea.
Polyzoarium divided into linear or sublinear branches or lobes, sometimes more expanded and lobate upwards, always decumbent, and closely adnate.

Gen. 1. Alato, Lamouroux.
Polyzoarium composed of a single or of multiple series of cells.
Alato, Lamouroux; Milne-Edwards; Johnston (pars); De Blainville; Fleming.
Millepora (esp.), Linn.
Auloporina (esp.), Goldfuss, &c.
Three or four species recent; several fossil.

Gen. 2. Tubulipora.
Polyzoarium arising from a contracted base, and expanding above; either simple or irregularly subdivided; decumbent and adnate below, usually free and suberect above.
Tubulipora, Milne-Edwards (pars); Johnston (pars); Fabricius; Torton; Gmelin; Ogewh (pars); Fleming (pars); Lamarck (esp.); Risco (esp.).
Tubulipora (esp.), Linn.; Jamieson; Stawert; Bosc.
Millepora (esp.), Ellis and Solander.
Collepora (esp.), Esper.
Florina (.), Lamouroux, &c.
Five or six species recent; several fossil.

Family 4. Discoporacea.
Polyzoarium in the form of a closely adnate, circular, or irregular disc or patch.
Tubuliporica (pars), Milne-Edwards, &c.

Gen. 1. Discopora, Lamarck.
Polyzoarium a circular disc, either flat, concave, or convex in the centre, with the suberect tubes opening irregularly in all parts of the surface, and usually surrounded by a thin calcareous border.
Discopora, Lamarck; Lamouroux; Fleming.
Tubulipora (pars), Johnston.
Millepora (pars), Lamarck.
Millepora, Quoy and Gaimard.
Madrepore, Ellis and Solander; O. Fabricius.

Gen. 2. Diastopora, Lamouroux.
Polyzoarium more or less depressed, circular, discoid; the cells subalternating, horizontal, immersed; openings elliptical.
POL

**Millepora** (sp.), Esper.
**Meehleriopora**, De Blainville.
**Diatopora**, Milne-Edwards (pars); Johnston (sp.);
Hagenow (pars).
**Aulopora** (sp.), Goldfuss.
**Boreaspora** (sp.), Lamonronx.

**Rosea**, Hémon.

**Avlopora** (sp.), De Blainville.
**Avlopora** (sp.), Lamouroux.
**Sub-Order**, Romer.

**Auto.**
**Gen.**
3. **Dtfrancia**, Bronn.

Polyzoary either discoid and adnate throughout, or fungiform and attached by a short stem; openings of tubes disposed in lines or rows radiating from the centre.

**Pedalia**, Lamouroux.
**Lichenopora**, Michelin.
**Tubulipora**, Milne-Edwards (sp.); Johnston (sp.).
**Ceripora** (anct., pars).
**Debrincia**, Bronn; Hagenow; Reuss.

**Sub-Order III. Icbonostomata.**

**Cells** corneous, or fleshly, tubular or depressed, free or coalescent; mouth terminal or sub-terminal, contractile, and when the polypide is exerted, surrounded with a fringe or row of sets, connected by a delicate membrane.

**Vesicularina**, Johnston.
**Polyzoa** cornea, Gray, and including—
**Polyzoa** cornea, Gray.
**Alcyoniadum** and **Alcyonidae**, Johnston.

**Cells** tubular or ovate, separate, arising from a basal tube common to all or to several; mouth terminal.

**Vesiculariadea**, Johnston.

(Fig. 25.)

**Cells** universal or biserial, and unilaterral, placed in close sets at stated intervals; basal tube divided into internodes.

528

**POL**

**Seriolaria**, Lamark; Riio; Fleming; Templeton; Couch; De Blainville.
**Amathia**, Lamouroux, &c.

Three or four species.

**Cells** ovate or subtubular, disjunct, universal, and unilaterial; polypide with a gizzard.
**Vesiolaria**, Thompson; Farre; Johnston; Van Beneden; Couch.

One species.

**Gen. 3. Valeria**, Fleming.

**Cells** ovate, clustered in whorls at the joints of the basal tube; polypides without a gizzard.
**Valeria**, Johnston; Fleming; Farre; Van Beneden.
**Vasiolaria** (sp.), Thompson.
**Gen. 4. Boverbankia,**

**Cells** unilaterial, irregularly placed, sessile; polypide with a gizzard (armed with two teeth).
**Boverbankia**, Farre; Johnston; Van Beneden.

One species.

**Gen. 5. Ferrella.** (Fig. 27.)

**Cells** elliptical, scattered; polypide without a gizzard.
**Ferrella**, Ehrenberg; Johnston.
**Lagenella**, Farre.
**Lagynula**, Van Beneden.

Two species.

**Cells** tubular, supported on a common stalk, and branching out in a palmate fashion.
**Anginella**, Van Beneden.

**Cells** fleshly, immersed, angular; mouth terminal, simple, contractile.
**Holocyonella**, Johnston.
**Polyzoa** cornea, Gray.
**Alcyoniadum**, Johnston.
**Alcyonidae**, Johnston.

**Polyzoary** irregularly lobed, massive, fleshly, erect, or adnate.
**Aleyoniadum**, Ellis; Baxter; Pallus; Linn.; Olivi; Esper; Müller; Lamouroux; De Blainville; &c.
**Aleyoniadum**, Lamouroux; Gray; Hooker; Johnston; W. Thompson; &c.
**Holocyonella**, Farre; Van Beneden.
**Cyrtula** (sp.), Hassall.
**Sarcbochium** (?), Hassall.

Three or four species.

**Sub-Order IV. P. Pedicellinae, Gervais.**

Lophophore produced upwards on the back of the tentacles, uniting them at their base in a sort of muscular calyx.

**Family 1. Pedicellinae**, Johnston.

**Gen. 1. Pedicellinae, Sars.**

Polyzoide not retractile within the delicate closely adnate ectocyst, which is produced downwards into a long tubular pedicle, containing muscular fibres, and rising vertically from a creeping radicle tube.

**Hydra** (sp.), Fleming; Bosc; Lister; Sharp—
**Pedicellinae**, Sars; Johnston; Van Beneden.
**Lesia**, Milne-Edwards; De Blainville; Gervais; Hassall.
**Crominomorpha**, Van Beneden.
Two or three species.
**Sertiolaria** (sp.), Müller; Bosc; Lamark.

Three species.

**Order II. Polyzoa hippocrepia, Gervais.**

**Cells** disposed on a crescentic or horse-shoe shaped lophophore; eversion of endocyst only partial.
**Polyzoaria hippocrepia**, Gervais.
**Polyzoa hippocrepia**, Gray.
**Lemniadea**, Johnston; Allman.
POL 529 POO

Freshwater Polyoca, Allman.
Freshwater Bryooca, Hancock.
Bryozoaires Fluvialistes, Van Beneden.

Family 1. Cristatellidae, Allman.
Polyzoary free, locomotive.

Polyzoary saciform, hyaline, with a common flattened disc adapted for locomotion; orifices placed on the surface opposite to the disc, and arranged in several concentric marginal series; ova lenticular, with annular and marginal spines.

One species.

Family 2. Alcyonidae, Allman.
Polyzoary rooted.

A. Lophophore with two long arms.

Gen. 1. Lophopus, Dumboriot.
Polyzoary saciform, hyaline, with a disc which serves for attachment, but not for locomotion; orifices scattered; ectocyst gelatinous.
Polyta to Panache, Trembley.
Bell-Flower-Animal, Baker.
Nahe, Lamouroux; Deslongchamps.
Plumatella (sp.), Schweigger; De Blainville; Gervais; Lamarck.
Aleyonella, Raspaal; Johnston; Allman.
Lophopus, Van Beneden; Allman.

One species.

Gen. 2. Aleyonella, Lamarck.
Polyzoary tubular; tubes united by their sides; orifices terminal; ectocyst pergamnaceous.

Tubularia, Pallas.
Leucopha, Muller.
Aleyonum, Bruguiere.
Spongia, Schmiedel.
Aleyonella, Raspaal; Pallas (sp.); Allman, &c.
Plumatella, Gervais.

Three species.

Gen. 3. Plumatella, Lamarck. (Fig. 30.)
Polyzoary tubular; tubes distinct; ectocyst pergamnaceous.

Tubipora, Lamarck.
Tubularia, Muller; Lionnes; Vacher; Turton.
Nahe, Lamouroux; Deslongchamps.
Plumatella, De Blainville; Carus; Lamarck; Dumortier; Johnston; Gervais; Allman; Thompson; Van Beneden; Dalzeli; Schweigger; Risso, &c.

Ten species.

PLumatella cristata.

B. Lophophore with the arms obsolete.

Gen. 4. Fredericella, Gervais.

Polyzoary confervoid, composed of a membrano-corneons branched tube, with the branches distinct and terminated by the orifices, circular, with a smooth margin and tectal crown or annulus; ova bean-shaped, distal of annulus or spines.

Tubularia, Blumenbach; Gmelin.
Nahe, Lamouroux.
Diplopodia, M. Deslongchamps.
Plumatella, Fleming; Dumortier; Johnston.
Fredericella, Gervais; Van Beneden; Thompson; Allman; Johnston; Hancock.

Family 3. Paludicellidae.
Lophophore orbicular, mouth distal of valve. (Does not perhaps properly belong to P. hippocrepia.)

Gen. 1. Paludicella, Gervais.
Polyzoary membrano-corneons, branched; branches composed of a series of claviform cells, placed end to end, and separated from one another by complete septa; orifices tubular, lateral, placed near the former extremity of each cell; ova lenticular, with a narrow annulus.

Aleyonella (sp.), Ehrenberg; Nordmann.
Paludicella, Gervais; Van Beneden; Allman; Thompson; Johnston; Hancock.

POLYPODICTIGM, a genus of Plants belonging to the natural order of Filiata, the sub-order Polyphaceae, and the tribe Aspicaceae. The infusion is circular, attached by the centre; the veins are distinct after leaving the midrib. There are three British species:—
P. Lomites, with rigid simply pinnate fronds. Found in Alpine rocks.
P. aculeatum, with linear rigid bipinnate fronds; the pinnales obliquely decurrent. Common in hedge banks.
P. angustata, with the fronds lax, drooping, bipinnate, pinnales truncate below, distinctly stalked. Found in the west of England, on sheltered banks.

(Babington, Manual of British Botany; Lindley and Moore, The Ferns of Great Britain and Ireland, nature-printed.)

POMPHILIDE, a family of Fossilary Hymenopterous Insects. They are sometimes included with the Sphignidae. They have the collar either transversely or longitudinally square, with the abdomen more or less oval, and attached to the thorax by a very short peduncle. The legs are very long. The fore wings have two or three perfect submarginal cells, and another commenced at the tip of the wings. The species are called Sand Wasps, and are amongst the most ferocious of the insect tribes. The species of the exotic genus Pegan are amongst the largest of the Hymenoptera. The genus Ponomia is British. The species are very active, running amongst grass and other plants in hot sandy situations. They are quick in their motions, and their wings are constantly agitated. Their long legs give them the appearance of spiders. (Westwood, Families of Insects.)

PONERA (Latreille), a genus of Insects belonging to the family Formicidae. In this genus the neuters and females are armed with a sting. The pedicle of the abdomen is formed of a single nod; antennae in these individuals thickened at the tip; mandibles triangular; head sub-triangular. P. contracta is a small species, a native of England.

POOL, or WELSHPOOL. [Montgomeryshire.]
POONAHILITE. [Mineralogy, § 1.]
POOR LAWS. There have been several statutes making slight alterations and amendments in the details of the administration of these laws, but none calling for particular mention, any analysis or enumeration of their provisions being impossible within the compass of this article.

Under the head of PAUPERISM [Penny Cyclopaedia, vol. xvii. pp. 327-30], an account was given of the establishment of the new Poor Law in England in 1834, and of its early operation up to the year 1840. Since that time the number of Unions has been increased from 957 to 694, including 14,168 parishes in England and Wales, and leaving only 456 parishes which do not make returns to the General Poor Law Board. The new Poor Law had, on its introduction, effected a large reduction of the expenditure on the poor, but from 1839 a gradual increase took place for several years. In the former article it was shown that there was no connection between the amount of relief required by the poor and the size of their property. As the subsequent returns only confirm the same fact, we shall omit the price of wheat, 3 Y.
and give the total amount levied for poor-rates in each year. The years end uniformly at Lady Day. The second column gives the total amount levied for poor-rates, and the third the amount expended for the maintenance of the poor.

In the years above mentioned we may observe that in 1852 the average price of wheat was 35s. 4d.; in 1840 it was 68s. 6d.; yet the amount of relief shows but a small difference. The number of persons relieved is an imperfect guide to the amount of distress, as it does not distinguish, except as regards in-door relief, between a single meal or assistance for a lengthened period, but we add a few statements of numbers at different periods. In the quarter ending Lady Day 1840, there were 169,228 persons relieved in workhouses only, and the number continued to increase till 1843, when the number in the house was 238,660, and receiving out-door relief 1,300,530. The numbers then slowly decreased till 1847, when the in-door went down to 146,406 and the out-door to 1,456,213, increasing respectively in 1848 to 305,056 and 1,370,585. Until 1848 the quarter ending Lady Day was taken as representing the number of persons relieved in each year. Since then the numbers in receipt of relief on Jan. 1 and July 1, have been taken, being the periods of greatest and least distress. Thus, on Jan. 1, 1849, there were 131,591 persons in the house, and 855,275 receiving out-door relief; on July 1, there were only 102,651 in the house, and 753,885 receiving out-door relief. The estimated total for the two quarters, however, including 214,870 for places granted and included in the returns, was 1,043,886. In 1853 the number similarly calculated had sunk to 857,035. On Jan. 1, 1857, the total number of paupers in receipt of relief, in-door and out-door, in 624 unions and parishes of England and Wales, was 843,340, being a decrease from 1856, in the same number of unions, of 33,255, or 3.8 per cent. Of adult able-bodied paupers relieved, exclusive of vagrants, there were 139,180, a decrease of 10,041, or 6.9 per cent. Of the number relieved in 1856, 12,042 were widows, or in the same class of 2291. Of the gross number of able-bodied paupers, 22,358 were in the receipt of in-door relief, a decrease of 1128 only, so that the chief decrease is in out-door relief. The greatest decrease took place in Bedford, Lancaster, Nottingham, Rutland, and Cirencester, where it exceeded 20 per cent. In Kent, Hereford, Durham, Oxford, Suffolk, and Worcester, there was an increase, as also in several of the Welsh counties. Of the in-door adult able-bodied, there were 842 married men, 1077 married women, 5052 other males, and 14,657 other females. Of the outdoor adult able-bodied, 53 males had been relieved in cases of sudden or urgent necessity; 17,210 males in cases of their own sickness or accident, 8936 males in cases of sickness or accident in their family, or for a funeral: 3784 males for want of work or other causes; 22,330 females were wives of adult males, 50,382 were widows, 5114 were single white women without children, 2690 the mothers of illegitimate children; 2018 were wives relieved on account of the insufficiency of food in their families, and 1298 were wives of soldiers, sailors, and marines; and 4389 were wives of other non-resident males.

The amount expended in the half year ending Lady Day 1857 for the relief of the poor was 1,979,882, of which 493,076£. was for in-door maintenance, and the remainder for out-door relief.

Ireland. In consequence of the distress occasioned by the potato famine the numbers relieved in that country also increased. It was considered necessary to provide a poor-law for Ireland. Accordingly, in 1838, an Act (1 & 2 Vict., cap. 50), mainly founded on the reports and recommendations of Mr. (now Sir George) Nicholls, was passed. In its main features it resembled the English poor-law, but the workhouse as a test of need was more stringently enforced. Mr. Nicholls was appointed chief commissioner, and under his direction it came into operation in 1839. The unions were formed gradually, and the expense of the system continued to increase. For a time this amount were granted for that purpose by government, a considerable portion of which was subsequently remitted. In 1840 there were but four unions in operation, North and South Dublin, Cork and Londonderry, and in these there were in the year 10,910 had been relieved in the year, and the expenditure had been 37,057L. On Dec. 31, 1841, there were 37 unions in operation, and there had been relieved 31,108 destitute persons, and 15,246 were then in the workhouses; the expense was 88,273£. On Dec. 31, 1844, 31,072 persons in 92 union workhouses, 87,904 persons had been relieved, and the expense had been 881,233£. On Dec. 31, 1843, there were 33,510 inmates in 106 workhouses, 19,414 had been relieved, and the expenditure had been 984,374£. On Dec. 31, 1844, there were 39,175 inmates in 113 workhouses, 105,365 persons had been relieved, and the expense had been 299,307L. In 1845 another period of distress occurred through the failure of the potato, and the number of the destitute continued to increase. On Dec. 31, 1845, there were 42,065 inmates in 123 workhouses (in March 1845 there had been 50,717), 114,205 persons had been relieved, and the amount spent 316,092L. In 1846 the potato-rot continued, and the distress increased to an extent unparalleled in the history of Ireland. It was caused by its relief by providing public works to employ the able-bodied, by reducing the duty on the import of corn, and by furnishing food at a low price to the destitute poor, in which it was thought also to have been greatly assisted by the Act of 1843, which was estimated to have amounted to 88,004, the whole sum contributing amounted to 531,372. The greatest number of persons employed at one time on public works was 97,000. On Dec. 31, 1846, in 130 workhouses there were 94,437 inmates, 248,333 persons had been relieved, and the expense had been 420,901L. But the evils arising from the continued failure of the potato continued to operate. Food was scarce, and the public works, instead of alleviating the distress, seemed likely to increase it. Agriculture was abandoned in many districts, the government was unable to prevent this, funds were wasted, and ten thousand left their trades. In October 1846 there were 11,040 men employed; in January 1847 the number had increased to 570,000; and in March to 734,000. It was evident a change of system must be adopted. Experiments were made to apply again the workhouse test, and the number rapidly fell, in April to 520,000, in May to 419,000, in June to 101,000, on the 26th of which month it was reduced to 23,000, and in August the system was discontinued. Cooked food had also been given to the poor in large quantities; 12,984,000 persons had been relieved in the year 1846, and they were given in separate rations. The entire amount advanced by government in 1845 and 1847 had been 7,132,268L., and the amount subscribed had been upwards of half a million. It was in these circumstances that the Act of 1847 was passed.
They found a poor-house of very inadequate accommodation, and the system was almost uniformly one of out-door relief. The report recommended a legislative enactment for a regular system of poor-laws, and accordingly in 1845 the 8 & 9 Vict. c. 53 was passed, by which the management elected by the rate-payers, a board of supervision, gave the power of levying assessments; the option of combining parishes for the erection of poor-houses; made a more certain provision for relief of the lunatic, casual, and unemployable poor; provided for not only the buried, but it still leaves a body of adult without a legal claim on parochial assistance. Each parish is allowed to decide whether the requisite sum for the relief of the poor shall be found by the rate-payers for immediate relief, or assessment, and if by assessment, how certain properties shall be classed; but having once decided in favour of assessment, they cannot retract such decision without the consent of the board of supervision. The voluntary system had been the custom, and cost of 660 parishes in Scotland, only 260 were legally assessed in 1842-43; these have been gradually increased, so that now (1858) there are but few in which a legal assessment has not taken place. Although the Act was brought into immediate operation, it was some time before the registers and accounts could be reduced into proper form. Officers and inspectors were alike inexperienced. But according to the best returns the commissioners could obtain from the several parishes, the expenditure for the year ending February 1, 1845, was 282,615L. From the returns made in 1843 it appeared that from all sources there was raised for the relief of the poor in 1836 the sum of 171,047L., and 216,481L. in 1841; the amount having gradually increased in every subsequent year. The number of poor in those years is not stated, but it is known that in 1841 there were 63,070 on the poor roll. In the year ending February 1, 1846, there had been raised 306,042L., of which 292,232L. were expended in poor relief.

In the autumn of 1846 the potato rot visited Scotland, and again in 1847, it caused a vast amount of distress, particularly in the Western Highlands and Islands of Scotland. Government aid was offered, and poor-houses and medical relief were strongly recommended, and in most instances adopted, particularly that of medical relief. For the year 1848, the number of poor was given in the annexed table. The years end on the 14th of May.

During these years the highest number of the poor on the register was 82,357 in 1849, the lowest 69,433 in 1846; the greatest number of casual poor relieved was 126,568 in 1844, the lowest 46,091 in 1852. The number of insane or fawning poor average about 2550; and the number of orphans or deserted children have increased from 4794 in 1847 to 5828 in 1853. The figures for the preceding years are but little in their details, showing chiefly an increase as the system extends, and we therefore give the latest published. In the year ending May 14, 1857, the total amount expended in poor-law relief was 629,348L., including 27,577L. on buildings, on medical relief 61,553L., on legal charges 27,977L., and on management, 7398L. The number of registered poor who received relief in the year ending May 14, 1857, was 88,082, a decrease of 10,740 from the previous year; and the casual poor receiving relief amounted to 36,545. The number of poor-houses in 1856 numbered 30, belonging to 190 parishes, either singly or by combination. Making accommodation for 10,000 persons, of which 294 in 1848 increased to 16 others were added in 1857. The number of registered poor on the 14th of May, 1857, was 62,017. (History of the Poor Law. By Sir George Nicholls.)
PORPOISE, or PORPESSE. [Wales.]

PORT HOPE. [Canada, S. E.]

PORT LINTON. [South Australia, S.]

PORT MACquarie. [New South Wales, S.]

PORT PHILLIP. [Victoria, S. E.]

PORTER, ANNA MARIA, born at Durham about 1751, was the youngest child of a family all of whom attained considerable celebrity. Her eldest brother was an eminent physician; her eldest brother was the Rev. Mr. Porter; her eldest sister was Jane, the subject of the following notice. When only a few months old her father died, and the mother, for the sake of educating her children economically, removed to Edinburgh. As a child her quick and original perception of the precious and intelligent child attracted the notice of Sir Walter Scott, then a youth, who delighted in relating tales to her, and this probably led to her own early attempts in the same line. While still almost a child she had written 'Artless Tales' in two volumes, which were issued in 1793 and 1795, of which she afterwards regretted the publication. Her mother had before this time removed with her family to London, and subsequently, with her sister Jane, they settled first at Thames Ditton, and finally at Esher. After the death of her mother in 1811, while travelling in hopes of restoring her delicate health, she was attacked by typhus fever, and died on June 21, 1832, at the seat of Mrs. Colonel Booth, Montpellier, near Bristol. Her literary productions were, until her death, little known to the public, but she had published numerous novels, among which 'The Hungarian Brothers,' 'Don Sebastian,' 'The Recluse of Norway,' 'The Village of Mariendorp,' 'The East of St. Magdalen,' and 'The Knight of St. John,' enjoyed and retain considerable popularity. Her novels have some of the several maxims and plots of sentimental novels, and show skill in the management of the story, and some discrimination of character; but her heroines and heroines too often possess a superhuman excellence that becomes part of 'The Folly,' a work published anonymously, and are intended to inculcate kindness to animals. In 'The Barony' she has developed her religious feelings. She also published a volume of poetry, 'Ballad Romances and other Poems,' in 1811, of no great value.

Her other sister, sister of the preceding, was born in 1776. Her life followed that of her sister, with whom and her mother she constantly resided till their deaths. She, too, as she described herself, 'became a wanderer,' living with one or other of her friends till, in 1842, she went with her brother to St. Petersburg. On his death she returned to England, and resided with her eldest brother, the physician at Bristol, where she died May 24, 1850. Miss Jane Porter did not adventure into the field of literature. Sister Mary was not a member of the butterflies of the society, but she was better prepared, but she has the same fault in the unmitigated excellence or depravity of her characters. Still, in many of her characters there is a firmer delineation, and perhaps somewhat greater knowledge, though not very rigidly adhered to, of the particular time of the story. Her first work was 'Thaddeus of Warsaw,' published in 1803, which was extremely popular, and procured for her the admission as a canoness into the Teutonic order of St. Joachim, and a complimentary letter from Kossiakin. In 1809 she published the 'Scottish Chiefs,' a romance of Wallace and Bruce, in which there is considerable vigour of description, some character, but a total misconception of the condition of the time. Wallace and Bruce are depicted as Rizzio and the deposed. To these are added the 'Pastor Fidei' and 'Duke Christian of Lounberg,' the latter said to have been suggested by George the Fourth. She next joined with her in 'Tales round a Winter's Hearth,' and these were succeeded by 'The Field of Forty Footsteps,' founded on a London tradition connected with the spot where now stands University College and Hospital, and which was almost immediately dramatized. After a considerable interval, during which she contributed largely to periodical works, unnoticed by anyone of the story of her African traveller, in the 'Naval and Military Journal,' she published anonymously in 1831 'Sir Edward seaward's Diary,' in which she so successfully imitated the style and adhered so closely to the manners and history of the period, that it is still read whether or not it was a fiction. This was her last work.

PORTER, GEORGE RICHARDSON, was born in London in 1792. He was educated at Merchant Taylors' school, where he became intimate with the Ricardo family, and subsequently married the sister of David Ricardo. His father, a merchant in London, designed him for his own profession, and he became a sugar-broker. He was unsuccessful in trade; but his commercial knowledge was made available for literary objects. In 1830 he published a work, 'On the Establishment of the Sugar-Cane.' A paper on 'Life Assurance' was published in the 'Companion to the Almanac for 1831.' In the same year 'A Treatise on the Origin, Progressive Improvement, and Practical Results of the Method of Cultivation of the Sugar-Cane.' A paper on 'Life Assurance' was published in the 'Companion to the Almanac for 1831.' In the same year 'A Treatise on the Origin, Progressive Improvement, and Practical Results of the Method of Cultivation of the Sugar-Cane.' A paper on 'Life Assurance' was published in the 'Companion to the Almanac for 1831.' In the same year 'A Treatise on the Origin, Progressive Improvement, and Practical Results of the Method of Cultivation of the Sugar-Cane.'

In addition to the above political divisions, each of the sub-provinces or districts is subdivided into commaras (or judicial divisions), cancehlos (or communal divisions), and parishes. The total number of commaras is 111; of cancehlos, 379; of parishes, 2774.

PORTUMNA, Galway, Ireland, a market-town and the seat of a Poor-Law Union, is situated at the head of Lough Dergh, in 53° N. lat., 8° 12' W. long., 41 miles E.S.E. from Galway, and 94 miles W.S.W. from Dublin. The postoffice of Portumna was 1542, besides 147 in the Union workhouse. Portumna Poor-Law Union comprises 15 electoral divisions, with an area of 77,046 acres, and a population in 1841 of 30,714; in 1851 of 19,731. The town has been much improved by the increased trade of the Shannon. It contains the parish church, a handsome structure in the perpendicular style; a large Roman Catholic chapel; a dispensary; Union workhouse; and bridewell. The Shannon is here crossed by a causeway and wooden bridge 880 feet in length. Quarter and petty sessions are held in the town. Saturday is the market-day for provisions. Fairs are held six times a year. Portumna Castle, a fine baronial mansion, the seat of the Marquis of Clanricarde, was destroyed by fire in 1826.

POITOU. In the 'Penny Cyclopaedia,' vol. xxviii. p. 453, there was given under this head an account of the Post-office up to and inclusive of the improvements introduced by Mr. Rowland Hill. All that remains is to notice what has been done in the way of extension of the advantages derived from rapid and cheap intercommunication, and a few figures to show the enormous increase which has taken place. In 1858, as stated in the previous article, the total number of documents transmitted by post, including franked, public statues, and newspapers of which there were 44,500,000, was 155,453,855. In 1859 the new system was introduced, but 1860 was the first entire year of the penny postage, but then letters might be paid, or stamped, or were charged only. In that year 1,35,165 letters only passed through the post-offices of the Kingdom; the revenue derived from the post-office had been 1,640,088l. in 1839; in 1840 it only amounted to 492,614l. In 1845 the number of letters had reached 329,101,611, and the revenue 760,889l. The number of letters that took a part in the net revenue continued to increase rapidly. In 1848 the additional advantage was given of a book-post, by which single books could be sent, open at the ends, at a uniform rate of 6d. per pound. This privilege was gradually extended to the Border counties. In 1856 the rate of postage on printed sheets was reduced to one penny for a quarter of a pound, twopence for half a pound, and twopence extra for each fraction above half a pound; but if fourpence or morewards were sent the packet might contain any number of sheets written or printed, except that the writing must not be of the nature of a letter. The last regulation in 1857 is that the packet may contain, in every case, any number of sheets, written or printed, but the written matter must not be of the nature of a letter, and may consist of bound books, or maps or prints on rollers, or whatever is necessary to the safe transmission of literary or artistic matter, such packets, however, not to exceed two feet in length, depth, or width, and all must be open at the ends or sides. Such packets are also to bear the British Arms on the outer end of the packet, 3d. for 4 oz., 6d. for 8 oz., and then proceeding at the rate of 6d. for every 8 oz., or portion thereof, except to Ascension Island, the East Indies, Hong Kong, Australia, New Zealand, the Indian Ocean, or the Great Eastern, in each of which all the additional 3d. is charged, and the weight is restricted to three pounds. By various conventions the foreign postage of letters has been materially reduced, in some cases 50 per cent, and in others varying from 17 to 20 per cent. The rates to all the British Colonies were reduced to an uniform rate of 6d. per half ounce, payable in advance.

The fourth annual report of the Post-office for 1857 states that the total number of letters delivered in the year was 504,421,000, of which 410,000,000 were in England and Wales, 42,806,000 in Scotland, and 31,612,000 in Ireland. These numbers give an average, in England, of 21 letters for each person of the population (in London it amounts to 43 for each), in Ireland to 7 for each, and in Scotland to 16 for each person. The number of newspapers passing through the Post-office was 71,000,000, about three-fourths of which bore the newspaper stamp. The number of book-packets was about 6,000,000. There were 580,000 newspapers, and 1,700,000 letters that from various causes could not be delivered, chiefly illegible or unlegible, for which the post-office paid 6d. for 4 oz., and the gross revenue was 2,928,858l.; the cost of management 1,720,615l.; and the net revenue 1,322,237l. The cost of management includes the following items:—Salaries, pensions, &c., 945,974l.; buildings, 25,077l.; conveyance of mails by land and sea, 25,977l.; expenses of the post-office, 11,725l.; wages of stamp-keepers, 105,000l.; by mail-packets (when paid for by the Post-office) and private ships, 12,268l.; for manufacture of postage-stamps, 35,065l.; miscellaneous, including conveyance of mail-bags, 16,357l. In 1857 the post-office received the conveyance of the postmaster-general, the conveyance of the mails through Egypt, clothing for letter-carriers and guards, rents, taxes, law expenses, &c., 109,672l. The business of the Money-order Office has also greatly increased; and, while it affords great advantages to the public in the transmission of small sums, has become a source of profit to the establishment. In 1857 the total number of money-orders issued in the United Kingdom was 6,386,702, to the amount of 1,210,273l., an increase of 91 per cent. In France it was 1,762,305, to the amount of 10,410,863l., were issued in England; 449,692, to the amount of 1,618,537l., in Ireland; and 518,874, to the amount of 950,872l., in Scotland. The commission gave a receipt of 9d. 6d. after the issue, in England, in 180,513, and in Scotland in 1180l.; in Ireland there was a loss of 616l. The number of orders gives an average of 1 for every 4 persons in England, for every 6 in Scotland, and for every 14 in Ireland. Money-order offices have also been established at Malta and elsewhere.

In 1855 some important improvements in matters of detail were introduced with great success. Country letters to London, or passing through London, were either sorted at the provincial offices or during their transmission, and this expedited the morning delivery. London by near an hour. Pillar letter-boxes were also erected in London, Edinburgh,
Dublin; they have been since extended to most considerable places in the United Kingdom, and of these there are now 703. London was also divided into 10 districts, each having a district head-office, by which letters posted in a district for a post-office, requiring to be transmitted to another not being in the same city, were conveyed by a transmission to the chief office, and thus a more speedy delivery is attained; and this division also greatly facilitates the sorting of inland letters; but to effect this the initial letters of East Central, West Central, North, East, South, West, North-West, South-West, South-East, and North-East must be distinctly placed at the end of the direction after 'London.' A book, price one penny, has been published, distinguishing all the streets and places within the different districts.

Nearly every town of any size throughout the three kingdoms has at least two deliveries a day from and to its metropolis and the larger provincial towns. In 1856 there were 52 such towns added to the list; for instance, in 1856 Manchester has four daily communications daily with London, Birmingham, Oldham, Bradford, Ashton-under-Lyme, Halifax, Sheffield, Wakefield, and Cheetham; seven with Liverpool; and five with Leeds, Stockport, Rochdale, and Bolton; twenty-nine mails are despatched from, and the number received at, the Manchester post-office every day. In 1866 the mails within the United Kingdom were conveyed daily over 129,480 miles of way; of this 20,172 miles are by railway at an average rate of ¾d. a mile; 25,997 by coaches, mail-carts, &c., at an average rate of Id. a mile; 63,450 by sea; an average rate of ½d. a mile; and 2879 by packets and boats between different places in the United Kingdom, at rates varying from 5d. ¾d. a mile to 4d. The total number of persons engaged in the service of the Post-Office in the United Kingdom has now become nearly 29,000. On December 31, 1857, including 1 postmaster-general; 5 secretaries, assistant secretaries, and secretaries for Ireland and Scotland; 15 surveyors; 19 other superior officers, such as heads of departments, chief clerks in the Metropolitan office, &c., 11,101 postmasters, 6116 clerks (exclusive of some employed temporarily); 204 guards; 10,427 letter-carriers, messengers, &c.; 8 marine officers; 125 postmasters, clerks, &c., in the Colonies; and 51 agents in foreign countries. Of these 11,101 postmasters are allotted to the United Kingdom, and (including this number) about 3200 are employed in the London district.

The third annual report of the postmaster-general for 1856, in an Appendix, states that "in no part of the United Kingdom has more been done for the welfare of the people by the use of railways for carrying mails and by the penny postage system than in Ireland." In 1874 there were posts six days a week on only four lines of road; letters to all other districts were carried only three days a week. Now there are daily posts to almost every village, and but one important town that has not two daily mails both with London and Dublin. In 1784 the whole expense of the office in Ireland was 15,000l., including salaries of provincial postmasters and their clerks. At present the amount of mail only was allotted to the provinces; the sum now (1856) allotted for the like service is 124,000l., divided thus:—conveyance of mails by railways, 65,500l.; by coaches and cars, 27,162l.; by foot-messengers, 10,334l.; and salaries and wages paid in provincial offices, 31,122l. In 1829 the cost of conveying the mail by mail-coaches was nearly four times the average rate of England; this excess has now disappeared, and in 1856 the average rate per mile was for England 11½d., and for Ireland 16d., and for Scotland 15½d. The same paper pays the following just tribute to the exertions of Mr. Bianconi for the improvement of intercommunication in Ireland, particularly in reference to the transmission of letters. In 1815, Mr. Bianconi first carried his Majesty's mails in Ireland; but he did so for many years without any contract. He commenced in the county Tipperary, between Cannel and Cahib; and he then made his own bargain with the post-office, that he should carry the whole mail of many small postmaster usually retained one moiety of the sum allowed, as his own perquisite, and Mr. Bianconi performed the work for the remainder. What Mr. Bianconi received was thus very small; and he was hot and would not therefore run at any hours inconvenient to himself past his accustomed road, but was convenient to him. From 1830, when the English and Irish offices were amalgamated under the Duke of Richmond, the public, as Mr. Bianconi says, got something like fair play; and he and others were allowed to carry the mails by direct contract with the Post-Office. From that time till 1848 Mr. Bianconi continued to increase his establishment; and in the latter year he had 1,460 horses, and daily covered 3,600 miles. The opening of railways was, however, a great check to his business, and in 1855 he was entirely interfered with this traffic, as to expel his cars from all the main lines. But Mr. Bianconi has met the changes of the times in a resolute spirit. He has always been ready at a moment's notice to move his horses, cars, and men to any district, however remote, where any considerable amount of mail was of itself, and not through the winter of 1855-56, when nearly the whole of that district in which he was working ten years since has been occupied by railways, he still daily covers 2980 miles, and is the owner of a large and well-arranged establishment, now working in the town of Wexford in the south-east, to the mountains of Doneygal in the north-west. Mr. Bianconi has done the State good service. By birth he is, as is well known, an Italian, but he is now naturalised, and England, as well as Ireland, should be ready to acknowledge his services. Perchance he may be persuaded that no living man has worked more than he has for the benefit of the sister kingdom.

The amount of postage collected at different towns in the United Kingdom (including the postage-stamps sold by the Post-Office and by the Board of Inland Revenue) shows some curious results. London, of course, through which pass nearly one-half of the total correspondence of the kingdom, attains a great predominance, the amount in 1857 being 159,900,000l., including 15,800,000l. for the delivery of mail-coaches, 104,655l., while Manchester, with 316,000 inhabitants, only contributes 97,756l.; Birmingham, with 322,000 inhabitants, but 42,107l. Bristol, with about 100,000 inhabitants (including Bedminster), furnishes 31,364l.; and Leeds with 272,000 contributors 28,100l. Now these are considerably more than 135,000 inhabitants, no more than 16,565l. In Ireland the contributions are more in accordance with the size of the towns:—Dublin contributes 60,391l.; Belfast, 16,547l.; Cork, 11,914l.; and Limerick 5,276l. In Scotland,—Edinburgh, with 160,000 inhabitants, contributes 59,177l.; and Glasgow, with 358,000 inhabitants, only 68,871l. It must be recollected, however, that in many cases some towns are used as a sort of depot, from whence postage-stamps are distributed to the various under-postmasters.

POTATO, SWEET. [Botany.]

POTTINGER, RIGHT HON. SIR HENRY, Bart., G.C.B., was born in 1789, of an English family which had been long settled in Ireland. He was the fifth son of the late Edward Curwen Pottinger, Esq., of Mount Darragh, in the county of Down, by Anne, daughter of Robert Gordon, Esq., of Florida Manor, in the same county. He went to India as cadet in 1804. At an early age he attracted the attention of the civil and military authorities, and was particularly recommended for his capacity, as well as his ready store of information bearing on his profession. Rising by gradual steps, he became successively judge and collector at Ahmednaggar in the Deccan, political resident at Cutch, and president of the regency of the Bahawalpur State. In 1833, he was appointed a baronet, when General Kane was rewarded with a peerage after the Afghan campaign in 1839. He had scarcely returned to England when war broke out between England and China on account of differences relating to the opium trade. In this emergency he was sent out to China as ambassador extraordinary and minister plenipotentiary, and superintendent of the British trade in that country; and in this two-fold capacity he took very decisive measures. Having been appointed governor-general of India, he returned to India, where he and his able assistants, the Earl of Clonmacnoise, Sir W. Parker, the result of which was the capture of Amoy. The effect of this step was to throw open to English vessels a commerce with upwards of 300,000,000 natives, and the terms of the treaty were thought to be such as to add a guarantee against the necessity of the repetition of offensive measures. For these services Sir Henry Pottinger was made a Knight Grand Cross of the Order of the Bath, and governor-general of the presidency of the Indian Government; and returned to England in 1844, he was sworn a member of the Privy Council, and a pension of 1000l. a year was settled on him by a vote of the House of Commons. In 1846 he was again sent upon active service as successor to Sir Benjamin J. Hamley, at the head of a British force, which he had held until the September of the following year, when he returned to India as governor and commander-in-chief of the presidency of Madras. He returned to England in 1854, having previously been raised to the local rank of lieutenant-
PREROGATIVE COURT. One effect of the transfer of the jurisdiction of all the Ecclesiastical Courts to the Court of Law was, that the业务 Relatio notabilita has ceased to exist. This court, whose jurisdiction arose from the possession of bona notabilita by the deceased person in two dioceses, has consequently, although without formal abolition, altogether disappeared from our judicial system.
French. In 1819 he received holy orders, and in 1825, after performing for thirteen years the duties of various curacies near Chirkwidd, he was appointed to the vicarage of Cwmdu. This was his last preference. The rest of his life was passed in his professional labours, and in a great variety of voluntary pursuits. Mr. Price carved in wood, modelled in wax and cork, etched with some skill, could play on the Welsh harp by ear, and had the honour of presenting a harp from his own design to the Queen at Buckingham Palace, in 1842. He was a great Delaware of drawing, some of which were engraved as early as 1809, in his friend Theophilus Jones’s ‘History of Brecknockshire.’ He was a great promoter of the Esteeds, or meetings for the cultivation of Welsh learning and music, which were voluntarily born of the prizes. He was looked up to by most of his countrymen with enthusiastic admiration as an accomplished champion of his country’s language and literature. His health began to fail somewhat early, and he died at Cwmdu on the 7th of November 1848.

The best of his English works are collected in the ‘Literary Remains of the Rev. Thomas Price, with a Memoir of his Life by Jane Williams, Ysgafell,’ 2 vols, 8vo, Llandover, 1866-68. The first volume contains an account of a ‘Tour through Brittany,’ made in the summer of 1820, written in a lively and agreeable style, and peculiarly interesting as containing the observations of one familiar with the language and literature of Wales on the kindred language and literature of France. Mr. Price’s Memoir of the Remains of Ancient Literature in the Welsh, Irish, and Gaelic Languages; ‘An Essay on the Influence which the Welsh Traditions have had on the Literature of Europe;’ ‘A Critical Essay on the Language and Literature of Wales from Gruffydd ap Gwna to Ysgafell’ (in the eleventh century) to that of Sir Gruffydd Llwyd and Gwilym Ddu’ (in the fourteenth,) make up the remainder of the first volume. The second is entirely occupied with Miss William’s memoir, which is extensive and interesting comparative information, and presents the fullest picture that has ever been drawn of a Welsh literary life. By far the greater part of Mr. Price’s literary labours were in his native language: he was a contributor to fifteen Welsh periodicals, for which he made a selection of articles once a month, and under such a variety of signatures, that it would now be impracticable to form a collection of the whole. His favourite signature however was ‘Carn-Hasanes’ (‘Man of the Sunny Mound’), which was familiarly known to every magazine-reader in Wales. His great work in Welsh was the ‘Hanes Cymru a chenedi y Cynyr y Cynoesoedd hyd at Farwoloth Llewyn ap Gruffydd’ (‘History of Wales and the Welsh Nation from the Early Ages to the Death of Llewelyn ap Gruffydd,’ when the Welsh country was united with England. It was published in numbers, sometimes with long intervals, the first of the fourteen of which it consisted appearing in 1836 and the last in 1848, the whole forming a volume of about 800 pages. It contains a complete compendium of the best history of Wales extant in any language, and it is somewhat singular that no translation has yet appeared in English. The omission may serve in some degree to justify the complaint which Mr. Price was accustomed to make of the extraordinary neglect of Welsh literature and total ignorance of British History prevailing in England, and the consequent contempt evinced by the English for everything relating to Wales, in contradistinction to the high appreciation of Welsh living in Great Britain and the superior knowledge and desire for information on all subjects connected with the principality by the principal British scholars.’

On the subject of his native language, Mr. Price was so enthusiastic that his feelings sometimes outstripped his judgment. At the Eisteddfod at Welshpool in 1834, he exclaimed, in an oration in the Welsh language, ‘We are told our language cannot last; but let them inform us what language will last, and we will support it. We are not chafed and goaded to—it when we are satiated with the extinction of our native tongue—shall we not reply! shall we not say that we likewise perceive the seeds of decay in the English! Who can tell but that when the present English sleeps with the sleep of death, what language will ascend to the throne of empire? But our mountain tongue may yet rise some remains of the Britons to patriotism and glory.’ Most Englishmen, we believe, who have urged the adoption of the English language in Wales, have supported the measure not on the ground of its supposed superior duration in the future, but of its evident superior usefulness in the present.

A notion of Mr. Price’s, to which he appears to have attached considerable importance, was, after communicating it to the ‘Athenaeum’ and the ‘Allgemeine Zeitung,’ made the subject of a separate publication, ‘The Geographical Progress of Empire and Civilization’ (Llandover, 1847-48). Every one is familiar with the ideas of the ‘westward progress of empire,’ which the Americans are so fond of quoting from the writings of the ancients. Mr. Price, however, had made a discovery, ‘that the average rate of progress corresponds with that of the retrogradation of the equinoctial points, which is 60 seconds and a fraction in a year, and that every part of the globe, in consequence, forms a subject to periodical retardations and accelerations.’ ‘The focus, or pole, was in 1847,’ according to his speculations, ‘located in the northern portion of this island, near the Frith of Forth in Scotland, moving in the direction of the Somny Frith at the rate of four miles a year.” In the whole, Mr. Price’s works are more remarkable for vigour, animation, and learning, than for sound judgment.

PRICHARD, JAMES COWLES, an eminent ethnologist, was born at Ross in Herefordshire in the year 1795. He was educated for the medical profession, and took his degree of M.D. at Edinburgh. He chose for the subject of his inaugural thesis the physical history of mankind. This seems to have determined the current of his thoughts throughout his life. He published a number of works, among which are the most laborious ethnologists of his day. He commenced the practice of his profession at Bristol, and in 1810 was appointed physician to the Clinkon Dispensary and St. Peter’s Hospital. He also had a private dispensary, to which he brought a number of his patients. He was never able to unite with his professional duties, he still kept the subject of his inaugural thesis before his mind, and in 1813 he published his ‘Researches into the Physical History of Mankind.’ This work, which was originally published in one volume, was issued in a second edition in 1826, and a third edition was finished in 1849, extending to five volumes. From the period of the first publication of this work it took the first rank amongst ethnological works, and the last edition is still considered an important work that has hitherto appeared upon the physical history of man. Dr. Prichard, whilst an anatomist and physiologist, was one of the first to avail himself of the study of philology as a means of arriving at the history of the various races of men. His contributions to ethnology took a variety of forms. In 1832 he read an elaborate paper to the British Association, then assembled in Bristol, ‘On the Application of Philological and Physical Researches to the History of the Human Species.’ In 1834 he read a paper before the Royal Society on his labours on the physical history of man under the title of ‘The Natural History of Man.’ A second edition of this work appeared in 1845, and it has been translated into the French and German languages. He has likewise written some important papers on the physical sciences; the twelfth volume of the proceedings of the Zoological Society is a paper ‘On the Cranis of the Laplanders and Finelanders.’ He also published a work ‘On the Eastern Origin of the Celtic Language,’ in which he pointed out the relations between the Celtic languages and the great group of Indo-European languages derived from the east. Another work also arose out of his ethnological researches, which was entitled an ‘Analysis of Egyptian Mythology.’

All his writings were great and important department of science, Dr. Prichard was not inattentive to professional studies. His ethnological and philological reading naturally led him to contemplate man psychically, and we find him addressing himself successfully to the study of the nervous system, and the results of its deranged condition on the mind of man. In 1829 he published a work ‘On the Diseases of the Nervous System.’ This was followed by a ‘Treatise on Insanity.’ In this work he displayed great power in analysing mental phenomena, one of the first authorities on the subject of mental derangement. He was appointed visiting physician to the Gloucestershire Lunatic Asylum. He subsequently published a work ‘On the Different States of the Nervous System,’ a sequel to the one mentioned above. His contributions to the labours connected with insanity led to his appointment as one of the Commissioners of Lunacy in 1845. On this occasion he removed from Bristol to London, where he continued to reside till his death. Besides the works already

mentioned, Dr. Pritchard enlarged an essay which he read before the Philosophical Society of Bristol into a work entitled *The Influence of the Earth on Man.* He was also an extensive contributor to the *Cyclopaedia of Practical Medicine.* He was made M.D. of Oxford on the occasion of the installation of the Duke of Wellington as chancellor of that university. He was president during one session of the Royal Society of London, and md many other scientific societies, including that of the Surgeons. He was also president of the Ethnological Society, and published an anniversary address delivered before that society. He was a fellow of the Royal Society of London, and of many other scientific societies, including that of the Surgeons. He was also president of the Ethnological Society, and published an anniversary address delivered before that society.

London Illustrated News," and other newspapers having a large circulation. In this machine a central drum 206 inches in circumference is the central axis, turns on a horizontal axis. We copy the following description from C. Tomlinson's "Cyclopedia of Useful Arts and Manufactures." "The ink-stand and the columns of type are secured to the surface of this drum; the columns of type are placed vertically, and the face of type is theiphery of the columns. If any line is to be printed, the columns are moved to that line in the following manner. A slab of iron is curved on its under side, so as to fit the large cylinder, while its upper surface is fitted into facets, or flat parts, corresponding with and numbered with the width and number of the columns of the newspaper; between each column there is a strip of steel, with a thin edge, to print the 'rule,' the body of this strip being wedge-shaped, so as to fill up the angular space left between the columns of the type, and to press a second too soon or too late, the relative position of the columns on one side as compared with those on the other side of the paper will be out of register by 1-70th of an inch, viz., one inch; in which case the edge of the printed matter on one side will be an inch nearer to the edge of the paper than on the other side. This is prevented by having it to do as, to draw forward the sheets so as always to have the edge of one ready for the machine to take in. When the steam-engine which works the machine be put on a greater speed, the central drum, and all the attendant contrivances for the preparation of paper and the rapidity of which the place on close to present them; but only at those periods, rapidly recurring though they be, which are provided by the peculiar functions of the machine."

This machine, with certain modifications to adapt it for printing in America, in one of which it has been improved for the "Illustrated News," and was shown at work during the Exhibition of 1851; it has also been adopted in other instances where rapidity of production was necessary. Another machine, like that on the vertical principle, has been invented by the Messrs. Hove, of America, and several of those have been brought into use in London.

The inventive faculty has also been applied to methods for facilitating the arrangement of the type, with far greater effect than the above. Mr. James L. Tomlinson, of the Paris Exhibition of 1855, Mr. Knight says:— "During the last twenty years there have been various attempts to produce a machine that will, to some extent, supersede that portion of manual labour in printing which is called 'composition.' The composition of type is the process of putting together the letters of which a larger and more rapid machine might have been made, which a more rapid method of arranging moveable types was to be effected than by the ordinary method, it may be sufficient to say that by keys, like those of a pianoforte, some force might be applied to remove a single letter from its proper receptacle, and arrange it in a combination of words and sentences. In the ordinary method, the various types which are necessary for the usual language lie in separate cells before the compositor, those most in use being nearest to him. He has to lay each sheet of paper, to which, picking up letter by letter, he forms words, putting spaces between each word. As he approaches the end of his line, he finds that the next word is too long to come within the line, and he therefore divides it by a hyphen, or carries it over to the next line. He then proceeds on the same, so as to make the line fit closely, but not tightly. Now it is evident that if the most perfect instrument could be made to pick up the letters and spaces, the intelligence of the workman being entirely dispensed with, the process would be such as to call each of line. Hence every composing-machine must be an imperfect instrument.

But, nevertheless, it may in some cases be of the utmost importance to have the type picked up, and placed in order immediately after it has been run through the machine. In the case of an expedition between the logographic system of Major Benkowski, and the common mode (in which trial Mr. Rennie was referee), it was found that a compositor at Mr. Clay's printing-office picked up and 'insisted' 6000 letters in two hours and twenty minutes. He distributed or returned the same when used, to the case in fifty-one minutes. There were several composing and distributing machines in the French Exhibition, but the most remarkable one, and that which appeared most useful as it appeared to M. Didot and other competent judges, to approach nearer than any other invention to the accomplishing of this long sought for object, is thus entitled—'Machine à composer et mettre a l'usage du typographie, composée par Christian Börosen.' It was stated that a Copenhagen newspaper, of which a copy was shown, had been printed for some time by this method. It would be impossible to convey an adequate notion of the details of this machine without drawings. I will endeavour to convey, however, a faint idea of its general design. The columns of type are disposed in such position that the type is displaced. But of 111 sheets there are three in the first, each letter has two, three, or four nicks cut at its right and left letter being the same as another. A cylinder, which may be described as a large basin, has a number of metal edges placed vertically in its sides, upon which the types without any regard to order, being the matter for distribution, are rapidly slid by the dovetail nick.
When the basin is filled, it is inverted upon a cylinder of
considerable size below. Upon the rim of this cylinder is
a separate opening for the reception of each of the 111
letters, but no one opening is like another. The distributing
and the composing go on at the same time. The composition
is seated; with a treadle he moves the upper cylinder, which,
as it slowly revolves, finds in the lower cylinder, which is
stationary, a fit place for every separate letter as it descends
by its own gravity to the bottom of each metal edge. The m
happening to be composed of about a pound of gold. The
other at the same distance from its bottom, falls into the
\( m \) opening, which having points corresponding, alone can
admit it from its similarity of form, while the \( n \) having four
nicks, two broad and two narrow, passes into its own division,
and is cast as before.

"But whilst this process of distribution is steadily pro-
ceeding, without any care but to keep the upper cylinder
occasionally supplied with new material for its operation, the
process of composition is naturally, at the same time. The composi-
tion sits before a compact little frame of keys, each key having
a connecting wire for each division of the lower cylinder. He
strikes a key and the lower letter is instantly detached and
falls into a funnel-shaped receptacle below, where, without
being inverted in any way, it runs into a groove, and ranges itself
in its proper order, in the line of its fellows. This is a long
line of several feet. By an ingenious contrivance each such line is passed on one side, as it is completed, to
another compositor at the same time, his hand moving with
the due width of his page or column, and spaces out the
words in the ordinary way. I saw 1000 letters thus placed
in line in the short space of four minutes, and the spelling
and punctuation appeared as correct as in most matters of
composing, that can be performed by hand. A loss of time in
refilling the cylinders, and through other hindrances, is taken into account, it was stated by the ex-
hibitor that 60,000 types are set up and distributed each day.
This gives a rate of about 6000 an hour, which is treble that
of the ordinary compositors.
The interest connected with the question of 'Types for the
Blind,' to which considerable impetus was given by the
Society of Arts for Scotland at Edinburgh, which offered their
prize of \( 50 \) guineas for an invention that would greatly bring about a change in the intellectual education
of the blind. The publication of the article Burn in the
'Penny Cyclopaedia,' at a time when the minds of many
were thus directed, and the strictures therein contained on
the absence of intellectual training in most of the asylums,
also rendered essential benefits on this point. Dr. G. S.
Howe, of Boston in the United States, in 1833 contrived an
alphabet, founded upon that of Halli, of a very compact
form, in which the New Testament was printed in 1835 and
in 1836. The late Mr. John Alston, the treasurer of the
Glasgow Asylum, than whom no man connected with the blind deserves more honourable mention, contributed greatly to this educational movement. He contrived an alphabet, a little more
or less arbitrary, the evil which would follow is of isolating
the blind by putting them in a position to require special
teachers. He therefore adopted the plain Roman characters
derived of their small extremities—the same as that of
founders; and, finding that it would be easily read, it would
also enable any seeing person who could read to be a
teacher of the blind, be at once procured founts of type,
and published several works in raised letters; the success of
these for the purpose, and the wide circulation of the word,
has been very remarkable.

Having thus inquired for several years, he visited
more than once the principal asylums for the blind in the
kingdom. In his work 'Statements,' &c., published in 1840,
he says, that after the introduction of his system, 'I found
a considerable improvement. Subsequently I visited the
English institutions a third time, and found a very great
number who could read with ease and intelligence; and I
have reason to know that there are some hundreds reading
these books. In the year 1840, 20,000 were printed in an
alphabet of the \( m \) kind. It may be added, that Mr. Alston
also brought out some beautiful embossed music and maps, and
that he published a 'Practically English Grammar' for
children, in 4to.

The paper used for these works is strongly sized, to
retain the impression. In order to account for the great
sight of the Bible, it must be borne in mind that the paper
can only be printed on one side, and that the letters require
to be of considerable size in order to be distinct to the touch.
The printing is effected by a copper-plate press. The types
being strongly relieved, and liable frequently to give way
under the heavy pressure required, it was necessary to have
them re-cut four times during the progress of the work.
The whole of the work was executed at the expense of the
Gallows Asylum, a man and a boy acting as com-
postors, there being one pressman, and the ordinary teacher
acting as corrector of the press. These books are now used in
many of our larger institutions. In the present state of the
print office of the Roman alphabet, unfortunately.

An invention by Aloys Uuer, of Vienna, called 'Natur-
selfdruck,' deserves mention. It by impressions are taken
from the natural objects themselves, and by an ingenious
process brought into a form fitted for printing from. Some
of the specimens produced, such as the veins and markings
of agate-stones, are of remarkable clearness and beauty.
The invention, with some improvements in the process, has been
patented by Mr. Henry Bradbury, and the 'Fern Flora of
the United Kingdom,' produced by him in a folio volume,
with 61 plates, is a proof of its capabilities of affording all
the advantages of a herbarium, without the defects; as well
as to its being available for many other branches of natural
history.

In type-founding also an ingenious machine has been
invented. In this, by turning a crank-wheel, the metal is
injected with considerable force into the type-mould, brought
by the machinery in front of a reservoir of metal kept fluid
by steam. It is blown through a pipe and released in a few
seconds; the metal so delivered out of it, at a rate varying from six to ten times
the rapidity with which the operation can be performed by
hand. Both in casting by hand, and in the machine, the
mould is liable to become obstructed by particles of the
metal remaining, which the most established courts, called
the Court of Probate. The functions of this court are con-
finen entirely to deciding upon the authenticity of wills,
and upon the proper persons to whom administration is to be
given, and to seeing that the property of deceased persons,
and the rights of the
ous parties who claim it beneficially, the court has nothing
to do. These matters must be decided by the courts of law
and equity, as before the passing of the Act. The duties of
the Court of Probate are merely to see that the administration
of wills and administration is established in London, and district registrars are established in forty of
the principal towns of England. The office or registry in
which probate or letters of administration are to be sought,
is no longer determined by the locality of the assets of the
deceased person, but by the place where the deceased had a
fixed abode at the time of death. Should the testator or
intestate have a permanent place of residence in one of the
districts in the time of his death, the place of residence
of administration may be obtained at the registry of the
district. The executors or personal representatives
may administer either by the local officer or the central
officer of the most convenient office of search for any will whatever.
The practice of the Court of Probate in all contentious
matters is thrown open to the whole legal profession, so that
the monopoly of testamentary business enjoyed by advocates
and practising solicitors is broken.
The court is presided over by a single judge, who sits at
Westminster. An appeal from his decision lies direct to the
House of Lords.

In cases where a person dies in one of the forty districts,
leaving personal property under 300L., and real property under 300L., the County Court of the district has jurisdiction should any contention arise. From the decision of the County Court judge, an appeal, which is final, lies to the Court of Probate.

One principal advantage of the new system lies in the removal of the contest, which is now a matter of litigation, to a new tribunal, and the old question of bona fide, on which the necessity of obtaining prerogative probate or administra-

raction was founded. The rules of evidence in the Court of Probate are to be the same as those in courts of law and equity, and suits for debt are likewise assimilated to those of the courts of common law.

PRODUCTICAE, a family of Brachiopod from Mollusca, in-
cluding the genera Producta, Strophalosia, and Chonetes. The shell is concavo-convex, with a straight-hinge line; of two valves which are closely articulated, furnished with tubular spines; ventral valves convex; dorsal concave; internal surface dotted with conspicuous funnel-shaped punc-
tures; dorsal valve with a prominent cardinal process; haxial processes (7) subcentral; vascular markings lateral, broad, and simple; adductor impressions dentritic, separated by a narrow central ridge; ventral valve with a slightly
notched hinge line; adductor sac central, near the umbo;
cardinal impressions lateral, striated.

PROSTOMIUM, the front part, head, and antehumerus of the body, and are sometimes also called bristle worms in a general sense. There are a great number of species. They are found ranging from the Devonian to the Peruvian rocks of North and South America, Europe, Spitsbergen, Tibet, and Australia.

PROTOCOPUS has its shell attached by the umbo of the ventral valve. There are 8 species.

Chonetes contains 24 species, which are found fossil in the Silurian from the Carboniferous rocks.

PROPUT, SAMUEL was born on the 17th of September, 1783, in Plymouth—the birthplace of so many English painters. From earliest childhood he was noted for an irre-

proachable honesty and unworldliness. He was of a quiet turn of mind, and the passion increased with his years. His associate in his early artistic studies was Benjamin Hayden, but instead of yielding to the eager impulses after an unattain-
able grandeur of his enthusiastic friend, young Prout con-
tented himself with unceasingly sketching from nature the ivy-mantled bridges, mossy water-mills, and rock-built cot-
tages, which characterise the valley scenery of Devon.'

Whilst uncertain as to his future course, he had the good fortune to be introduced to Mr. John Britton, the antiquary, who, at that period, was in the midst of his great work, the account of Cornwall, which he was preparing for the ' Bean-
ties of England.' [Burtton, John, S. 2.] Mr. Britton, pleased with his sketches, proposed that he should accompany him to France. The young artist was elated, and immediately accepted the offer. The portfolio of Cornish drawings which he afterwards transmitted to Mr. Britton, excited by their boldness of style considerable notice, and the young artist was easily persuaded to remove to London.

He associated himself with an artist who was then in London, and found an adviser and patron in Palmer the printseller, then residing in the Westminster-road and afterwards in Fleet-street, who used readily to purchase his water-colour drawings, and dispose of them among his customers. Palmer gave but low prices for these works, but Prout had the good sense, on comparing his pictures with those of the established artists, to recognise his own deficiencies; and he was well pleased to be thus enabled, by means of numerous drawings, to support himself whilst making a resolve to extend his artistic knowledge by study and executive skill. During these years he painted marine views, especially coast-scenes with fishing-craft, more than any other, architecture, for which a very decided inclination had not yet developed itself. He also devoted a good deal of time to teaching, and he stuck some lessons and studies for the use of teachers and pupils; but receiving the capabilities of the newly-introduced art of lithography for yielding fac-simile of the painter's pencil-sketches, he began early to draw on stone with chalk and wash, having bought a stone as a formidable art, he did with great facility. He published in 1816 a series of 'Studies' which met with great success, and was followed by 'views in the North and West of England,' 'Progressive Lessons,' 'Remains of Landscape,' and other works of the same kind. The presentation of a series to extend his artistic knowledge the reliability of the basis that class of publication far above the estimation in which it had been previously held, and did much to extend the reputation of the artist.

Mr. Prout had already secured a high position, when he was led in 1818—partly in the hope of restoring his health, which had become much enfeebled, but also with a view to turning to professional account the taste for foreign scenery engendered by the facilities for continental travel opened to him by the appearance of the 'Modern Repository,' and the quaint street-architecture of Rouen, and the civic and eccle-

siastical structures of other Norman towns, seemed to reveal in him an entirely new sense. From this time he gave him-

self, with undivided zeal and unapproached success, to the delineation of the weather-worn and mouldering remains of medieval architecture. Year after year he continued to journey through the fairest parts of France and Switzerland, of Germany and Italy; but still it was the old southern or Tuscan manner that enabled him to tumble down heavy-gabled domestic houses which, though hardly ranking among any of the architectural divisions, had in his eyes an equal attraction in their antique picturesque-

ness. The reliable table of reproductions of the engravings he published a handsome folio of lithographic 'Fac-Similes of Sketches made in Flanders and Germany.' This was the first of the numerous series of lithographic copies of painters' finished sketches which have added so greatly to the enjoy-

PSAMMA, a genus of Grasses belonging to the tribe Arundinaceae. It is known by its flower being enveloped in long silky hairs, the lower glume shorter than the upper, and its panicles being spike-like.

P. arenaria, Sea-Reed, Marram, is the only British species. It is found on sandy sea-shores, where its roots assist in binding the shifting sands.

PSOLIDVM, characterised by the singularly clever introduction and arrangement of his figures, ill-drawn as these often were. In a word, Prout may fairly be regarded as the founder of a new school of architectural painting. He first showed what a world of picturesque capability lay in the quaint streets and market-places of Normandy, Flanders, and Germany, and the grander palaces of Venice; and no less did he show how to render the broad features and deep sentiment of the old ecclesiastical gothic, without being lost in a multitude of petty details.

PROUT, WILLIAM, distinguished as a chemist and physician. He was brought up to the medical profession, and took his degree of Doctor of Medicine at the University of Edinburgh. On establishing himself in London he connected himself with the Royal College of Physicians, of which body he ultimately became a Fellow. He early directed his attention to chemistry, and was amongst the first in this country to attempt to apply this science to the explanation of the phenomena of life, and he published many papers in reference thereto. It is with the 'Philosophical Transactions' of the Royal Society of London that we have to do. Amongst the subjects of his researches and discoveries on this subject were combined in a great work entitled 'On the nature and treatment of Stomach and Renal Diseases, being an inquiry into the connection of these affections with the diseases of the Kidneys and Bladder with Indigestion.' However brilliant the discoveries which have been made subsequently to the publication of this work, there can be no doubt that Dr. Prout had correctly appreciated the importance of chemistry, in explaining the functions of living beings, and was the first physician who sought to apply the doctrines of modern chemistry to the explanation of the phenomena of disease. He was an exceedingly careful and accurate experimenter, and with regard to some of his conclusions, which were at one time thought to be too far-fetched, a more careful investigation has confirmed the truth of his views.

Dr. Prout was one of the gentlemen chosen to write the 'Bridge-water Treatises.' The subject of his essay was 'Chemistry, Meteorology, and the Functions of Digestion considered with reference to Natural Theology.' This work abounds with evidence of his profound knowledge of the laws of chemistry. Although principally occupied with chemistry in relation to his profession, he took an interest in all sciences and discoveries, in his favourite science affected. He was one of the first to analyse the so-called Coprolites, and to discover the large quantity of phosphate of lime they contained. This he did in a paper published in the third volume of the 'Transactions' of the Geological Society. The paper was entitled 'On the Analysis of the Fossil faces of Ichthyosaurus and other Animals.' Dr. Prout was a Fellow of the Royal Society, and many other learned societies. He died at his house in Sackville-street, London, in 1829, at the age of sixty-four, in the fourth year of his life. He was a man of exceedingly reticent habits, and greatly respected by those who knew him intimately.
classes, their social circumstances, and their physical condition generally, far more unfavorable than they had previously been. Many of these propositions are supported by facts that appeared in their Report produced a strong impression on the public mind, already startled by the dread march of Cholera. When the Poor Law Amendment Act was brought into operation, the London Association for the prevention of the want of Medical Aid in Unions was formed, and published in the Annual Reports of the Commissioners, deepened and strengthened this impression, and led to a desire for a fuller and more specific investigation. Such an investigation the Poor Law Board determined to undertake, and, in the first instance, confined itself to the metropolis, being entrusted to Dr. Arnott, Dr. Kay, and Dr. Southwood Smith. The Reports of these gentlemen, which were printed in the Fourth and Fifth Annual Reports of the Poor Law Commissioners, disclosed an appalling extent of vice, vice, and social corruption, and led to the dire result of the neglect of the plainest and most rudimentary sanitary laws. The statements of the Commissioners, as might be expected, excited a very painful sensation, and the then Bishop of London (Dr. Blomfield) moved in the House of Lords (Aug. 19, 1839) an address to her Majesty, praying that a further inquiry might be made as to the disease and destitution prevalent among the labouring classes in certain districts of the metropolis; how far the same prevailed in other districts of England and Scotland; and what measures would be necessary for the removal of those evils. By a subsequent vote the inquiry was extended to Scotland.

The Inquiry was placed in the hands of the Poor Law Commissioners, who, having been organised by the Board, the local investigations were made, not only through the medium of the Assistant Poor Law Commissioners, and the medical officers of Unions, but much assistance was derived from the medical profession generally, the clergy, and others; and a large body of information was brought together of a kind similar to that previously obtained by the Metropolitan Commission. This information was arranged and digested by Mr. Edwin Chadwick, then Secretary to the Poor Law Board. His Report on the General Sanitary Condition of the Labouring Classes, published in 1842, presented not merely the fullest and most complete view that had been brought before the public eye of the physical and social condition of the labouring classes throughout the country, the causes of the prevalence of endemic and epidemic diseases, and the clearest and most comprehensive suggestions for remedying the evils shown to be so widely prevalent, but from it may be dated the origin of those important measures of sanitary reform which we shall presently have to notice. It contained the outlines of the system which were in fact here sketched. We must not, however, omit to mention, in noticing these pioneers of sanitary improvement, the very important statistical researches of Mr. J. E. Hawkesworth, which were published and relied on simultaneously with the inquiries just described, which have been continued to the present day, and which have served, and still serve, to give precision and specific directions to the observations of other inquirers.

In the Report of Mr. Chadwick, it was shown that whilst in each there were local and peculiar causes of mischief, in all the great towns there were common sources of danger and disease, in the existence of close and confined localities where the over-crowded houses were constructed, undrained, or insufficiently drained, damp, dirty, and ill-ventilated, and surrounded with numerous sources of malaria: the seats of almost constant fever and sickness, and that, as a consequence of their enfeebled physical condition, the inhabitants were the earliest sufferers in times of epidemic disease. So evident indeed was the influence of locality on disease, that Mr. Chadwick was able to show that, whilst the mean rate of mortality in a town would be represented as 1 in 22 annually of the whole population, in one district the mortality might be as in St. George's, Hanover Square, London, only 1 in 57; in another district of the same town (Whitechapel) as much as 1 in 28 annually; or to take another illustration, that whilst in one street and amongst a particular class of tradesmen the average duration of life was about 50 years in another street of the same town, amongst a different class, the average duration of life is only fifteen years. But it was further shown, that although almost necessarily owing to their rapid increase and the prevalence of disease—sanitary considerations having been entirely overlooked—the effects of particularised were, so to speak, intensified in towns like London, with its miserable purblind inhabited by thousands of wretched wanderers and outcasts; Liverpool, with its 8000 damp cellars, and its 8000 close courts, each with an opening communicating with a lane, were so filled with such persons that the stench from their houses was so disgusting, that they had to be air'd nightly by means of the mire, and the constant fall of visitation of fever, cholera, and similar diseases all were insufficiently drained and ill supplied with water; all had their St. Giles's, their pestiferous lodging-houses, their fever-nests, their labourers' dwellings, where comfort and cleanliness were impracticable, and where sickness and death were the constant sequel. At these statements in the mass and in detail, it was impossible not to agree with the report that this was a state of things disgraceful to the intelligence and civilisation of the country, and that immediate and comprehensive sanitary reform was necessary. Mr. Chadwick forcibly observed, it was incontestible, that the facts deduced, that "noxious physical agencies depress the health and bodily condition of the population, and act as obstacles to education and to moral culture; that in abridging the duration of the adult life of the working classes, they check the growth of productive skill, and abridge the amount of social experience and steady moral habits in the community; that they substitute for a population that accumulates and preserves itself, a population, which, being continually destroyed, is continually replaced, the young, inexperienced, ignorant, credulous, irritable, passionate, and dangerous, having a perpetual tendency to moral as well as physical deterioration." And happily he was also able to observe that the report had been another great warning to the general public, to the effect that mere sanitary measures, not only might the more palatable and offensive evils be removed, but that "it is probable that the full insurable period of life indicated by the Swedish tables, that is, an increase of thirteen years at least, may be extended to the whole of the working classes, the measures of the sanitary reform, if fairly carried out."

The remedial measures pointed out as of primary importance were the providing of a sufficient supply of good water to every house, an ample supply being at the same time furnished for the cleansing of the streets, for sewerage, for the collection and conveyance of sewage and offal, for the drainage by the adaptation of drains and public sewers, and the construction of water-closets in houses of every class; the preservation of the natural streams flowing near towns from the pollutions caused by the influx of the contents of the public sewers, and the employment of the sewage for agricultural purposes; the adoption of measures for securing a better class of labourers' dwellings; the licensing of common lodging-houses, and placing them under strict control; the adoption of measures to restrain the pollution of the air by the fumes of manufactories, &c., and the appointment of district medical officers, "independent of private practice, and with the securities of special qualifications and responsibilities, to initiate sanitary measures, to adopt all known means of improving the condition of the labouring classes, and to clean forward the inroads of mortality.

These suggestions have since for the most part been embodied in the Health of Towns Act, and other sanitary measures passed by the Legislature. The subject of intra-mural interment was also considered by Mr. Chadwick in a special report in the following year.

But, searching as had been the investigation, and undeniable as appeared to be the facts, and urgent as seemed the necessity for combating the wide-spread evil, so large an aggregate expenditure was requisite for executing the works, and so extensively would the suggested administrative organisation interfere with existing interests, and, as some might conceive, with local management and individual freedom of action, that it seemed to be necessary to submit the question to any legislative enactment without instituting still further and more formal inquiries. A Royal Commission, consisting of eminent members of both houses of parliament, civil engineers, and scientific men, was accordingly appointed, in 1844, for the purpose of inquiring into the state of the sanitary questions connected with the public health. The evidence collected entirely corroborated that of the former commissions,
and the conclusions arrived at were to effect the same as those of Mr. Chadwick. In their Reports, dated June 1844 and February 1846, they showed the great questions bearing on the sanitary regulation of populous places—sewerage, drainage, paving, cleaning, removal of nuisances, consumption of smoke, supply of water, public baths and wash-houses, ventilation, streets, buildings and streets, and interment in towns—were found, almost univer-
sally, all of them in an extremely unsatisfactory condition; and having examined the existing law with regard to those subjects, expressed their opinion that it would "be necessary to modify or even to sweep aside the aid of our legislators for further enactments, before the improvements so much desired can be fully accomplished."

Thus fortified, the ministers framed a bill embodying many of the recommendations of the Health of Towns' Commis-
sions. This bill was introduced by Lord Lincoln, then Chief Commissioner of Woods and Forests; but it was explained that it was introduced mainly with a view that its provisions might be carefully considered during the recess, and no attempt was made to carry it fur-
ther. A change of ministry interfered with its progress in the next session. In 1847, however, Lord Morpeth, who had succeeded Lord Lincoln as Commissioner of Woods and Forests, introduced an amended bill, but though, in conse-
quence of the recess, and the general measures of the ministry of Lord Grey, the bill was not read a second time; it was ob-
jected to withdraw the clause which included the metropolis within its provisions, he failed to carry the mea-
sure that session. In the next session it was again brought forward, and, its urgency having been placed on the attention of the country, the clause in question was removed from the throne, it was carried by both houses; and, on the 31st of August, 1848, it re-
ceived the Royal Assent.

The object of the Public Health Act of 1848, as stated in its preamble, is to make "further and more effectual provision for improving the sanitary condition of towns and populous places in England and Wales" [the metropolis being excepted from its operations]; for which purpose it is declared to be "expedient that the supply of water to such towns and places, and the removal of the nuisances and the cleansing thereof, should, as far as practicable, be placed under one and the same local management and control, subject to the general supervision of a 'General Board of Health,' consist-
ing of the First Commissioner of Woods and Forests for the time being, and two commissioners appointed by royal warrant, to whom the superintendence and execution of the act are to be entrusted. The Act is of great length, containing no fewer than 103 clauses; but as it is an Act of the greatest magnitude, and therefore has had a long and laborious course, it is advisable, concisely, to state, how, in the event of any alteration of it, the sanitary condition of the towns and populous places in England and Wales will be affected.

As the Act comes to be applied without a public preliminary inquiry, which the General Board had the power to order on the petition of one-tenth of the ratepayers of any such place as came within the cognisance of the Act, or where the average deaths for seven years should appear, from the Registrar-General's Returns, to be above £3 in a thousand. In either of these cases a superintending inspector may be sent—14 days' notice by advertisement, &c., having been given in such locality—to examine personally and by witnesses into the sewerage, drainage, water supply, burial grounds, &c., and report thereon to the Board. If the General Board now deem it expedient to apply the Act, the Queen may, if there be no local act, by an Order in Council order the Act, or any part of it, to be carried into effect; if a local act, the Privy Council may make a provisional order for its application, such provisional order to be afterwards sanctioned by parliament. In every such case the carrying out the pro-
visions of the Act is entrusted to the Local Board of Health created by it, who are to appoint a surveyor, an inspector of nuisances, and a medical officer, with other necessary officers. In a corporate town the members of the Corporation are to constitute the Local Board of Health, in other places the members are to be appointed by the Board; in all cases, the entire sanitary government is vested solely in the Local Board of Health.

As to the powers of the Local Board,—it is imperative on them to provide for the effective drainage of their locality, by the proper construction of sewers and drains for sewers and for house drainage by causing sufficient drains to be con-
structed in all new houses, or in any house which may be without a proper drain communicating with a main sewer; they may also cause due provision to be made as to privies, offices, &c., and public conveniences in houses and buildings, and when properly times causes a thorough surface cleansing and watering of all streets; provide for the storing and taking away of dust, &c.; and cause nuisances to be removed, and filthy and un-
wholesome buildings, &c., to be purified and whitewashed. The Board may also, as a last resort, provide for the accumulation of pure water, for the purposes of the Act; but not construct new water-works if a Company is able and willing to pro-
vide a sufficient supply on reasonable terms; and in any case the Board must obtain the consent of the Local Board before contracting to purchase old, or to construct new water-works or gas-works. The office of surveyor of high-
ways is vested in the local board, who must see that the highways are properly paved and lighted; that new streets and roads are formed in accordance with the terms of the acts of parliament. The local board may also, subject to the control of the General Board, close any unlawful burial ground, and provide general cemeteries for persons of all religious denominations. Also, subject to like control, form, or contribute to the form, of pub!

The intention of the Act in respect of local management and central control has been, in short, to cast upon the inhab-

...
door opened wide for a return to the old apathy, mismanage-
ments, negligence, to local inefficiency, want, perulation, and
favouritism. The "general medical functions of the
Board of Health" are to be dealt with in a separate
section, "they being distinctly central and govern-
mental functions.

Since the passing of the Health of Towns Act, appli-
cation has been made to the metropolis for a "preliminary
inquiry" into their sanitary condition by the inspectors
of the General Board. How much such an act was needed—
how little had been accomplished by mere local effort, not-
withstanding the ample provisions of the Public Health
Acts, the Law Board Reports, the Reports of the Royal
Commission, the Returns of the Registrar-General, and
the teaching of cholera and fever—has been shown in the
most convincing manner by these "preliminary inquiries," ranging in time from the past
year to the year 1858. Building does not exist in almost
every district of England and Wales. We had
selected from recent reports of the superintending inspectors
a few special instances as illustrating the present state of
too many "towns and populous places," not yet brought
under the cognisance of the Health of Towns Act, including
sea-side and inland watering-places and resorts of invalids;
mixing and manufacturing towns and villages in the north of
England and Wales; rural towns of the eastern, southern, and
western counties; but others have told, they, after all, but tell, with variations, the same sickening
story of wretched quarters—often in close, though scarcely
suggested proximity with the open and airy dwellings of
the affluent—dark, close, crowded, loathsome, undrained, and
wretched, carrying the stench of impure
supply of water, and, what is to be obtained, hard
and impure; many of the streets where fever is never absent;
lodging-houses where men, women, and children are huddled
together in close, filthy, over-crowded, and
abominations, in the very midst of the most
densely populated localities; burial grounds, surcharged, and
the like—seemingly in defiance of sanitary
principles; the most obvious to the commonest understanding,
but, in fact, the most neglected through the
part of the influential classes that such things exist, and
the absence of any responsible officer whose duty it is to make
himself acquainted with their existence and to apply
the remedy. In short, it may be said, that the
population of these towns and populous places, where every one has been left to
do as he likes with himself and his own, to illustrate the
evil consequences of neglect of sanitary regulations.
For the miserable loss of health and life among our soldiers at Scutari
and in the Crimea, where—as military authorities themselves
admit—the arms of the enemy slew but few in comparison
with the ravages of disease, and the recent astounding disclosures
respecting our barracks at home, more than sufficiently prove all the evils of our local
advocate of sanitary reform has
sustained the necessity for correcting these impure waters,
fulness, and authoritative control. Happily, too, in the
same quarter we have a striking illustration of the benefit of
sanitary regulations. For, both in the hospitals of the Bosphorus
and the Crimea, the rigorous and stringent
and precautionary measures of the Sanitary Commissioners,
sent out from England in January 1856, have been brought
into operation, than the number of deaths, and the amount
and violence of the sickness, were abated; and ultimately the
very remarkable fact was established, that notwithstanding
all the hardships, exposure, and fatigue attendant on a state
of warfare, the actual mortality was lower than in the barr
racks in England—a fact which renders the more strange and
incredible, from the number of those barracks which those barracks should afterwards have suffered to continue.

Up to the end of 1857 about 230 places had been brought
under the operation of the Health of Towns Act. In a fair proportion of these places sanitary works of an efficient
order have been executed. The sanitary works have of course been chiefly those of drainage and water supply, and in both these matters some of the works have been on a
scale of considerable magnitude. By the earthenware pipe drainage being used, and the rainfall
place or peculiarity of site, the local boards have in most
instances been enabled to effect thorough drainage with compara
tive readiness and economy. The utilization of the sea
water has not however yet been brought into general suc
cessful operation. And it appears as if those places have made that the successful drainage of the town has resulted in the pollution of the natural streams—a necessary con
sequence of such works where the outfall is into the water
courses, and no sufficient measures are taken for the utilisation of the sewage, and the purification of the waste water. The means adopted for obtaining and distributing an ample supply of pure water have proved generally satisfactory, and now in numerous places where only a scanty supply of hard and impure water was obtained, has been abun
dantly provided with water of excellent quality. And wherever these sanitary works have been judiciously
planned and properly carried out, there has followed a marked
improvement in the general health and comfort, while the
number of deaths from cholera and fever has been less
than in other places, and in some it is even stated that
the most part far less burdensome than where inferior works have been executed under the old local improvement acts.

To the improved health and decreased mortality in several
of these towns the Registrar-General has in his Reports
shown that these improvements have been brought about by
the Local Boards of Health themselves, thus the
Macclesfield Board say, in a Report addressed to the Town
Council, that the death tables of the borough show that the
mortality, which before the application of the Act averaged
33 in a thousand, has during the three years of the operation
of the Board been reduced to 26 in a thousand; that infantile
mortality—always a trustworthy test of sanitary condition—
has been reduced 15 per cent.; that in the "old towns of,
thousands and thousands of people are now enjoying a
mean duration of life in the towns has been lengthened. The
application of sanitary measures has not however been con
fined to the towns under the Health of Towns Act.
Several large towns which have been brought under the
Local Acts at Liverpool and Manchester, for instance, and
very costly works have been constructed for bringing to these places a supply of pure water from a considerable
distance; and at Glasgow a similar supply has been obtained, at
a great cost, from the Cartage-burnet river.

We stated that the metropolis was exempted from the
operations of the Health of Towns Act. Several Acts were
indeed passed to meet particular evils, but notwithstanding
that the necessity for stricter sanitary supervision was ob
erved, the Metropolitan Water Board had not been
incorporated and the parish vestries against centralisation
of authority, that it was not till 1856 that a measure intended
to secure to London the same sanitary improvements as the
Health of Towns Act offered to the rest of the country
came law. The Metropolis Local Management Act is how-
aver a far longer and more cumbersome measure than the former (it contains 251 clauses and several schedules), and its machinery is larger and more complex; it must suffice there
fore to say that its objects and scope are very similar, how-
ever different in some respects are its modes of operation.
The executive body created by it is entitled the 'Metropol
itan Board of Works,' and consists of a president, with a
council of 9 aldermen and 24 commissioners, each of whom is
called"metropolitan commissioner," who sits in the vestries of the metropolitan parishes, and the common
council of the city. To this board was transferred the
powers of the former Commissioners of Sewers, the super
vision of all metropolitan buildings, the laying out of new streets, etc., and the compulsory purchase of
land. But within certain limits a controlling power was entrusted
to the Chief Commissioner of Works and Buildings.
The great work which was cast upon the new board was the
purification of the Thames, by the interception of the sewage
of London, which the board was ordered by parliament to
accomplish. In this it has however made little progress, not
having been able to satisfy the government (or the public) of the
sufficiency of its plans. In other great matters, as the
removal of the dockyards to Woolwich, and the laying out of
the docklands, and the remodelling of the parks, &c., it has also been content to discuss and to plan.
In small matters its officers have found sufficient occupation.
But on the whole, as from its constitution might have been anticipated, it has hitherto proved rather a board of discus
sion than, as it claimed to be, a board of execution.
The Health of Towns Act, and special Acts similar to the
Metropolis Local Management Act, would pretty well suffice, if properly carried out, for the sanitary regulations of the
metropolis, and it may be said that the other towns of the
metropolis are hardly more than villages, and there are many towns in which such acts have no force, general
measures have been, and still continue to be, required to meet particular sanitary evils. We cannot enumerate all of these, but it may be convenient to mention the chief sanitary
laws of the metropolis. The most important of these is the
scheme for the establishment of Baths and Washhouses, passed
in 1846, is noticed under another head, [BATHS AND WASH
HOUSES, S. 2]; and as the Towns Improvement Act of 1847,
which consolidates previous acts respecting paving, draining, cleansing, and improving towns, and contains many valuable new clauses, created new machinery for carrying its provisions into effect, and accomplished much less than its framers anticipated, we may pass at once to the measures passed subsequently to the passing of the Act of 1851.

The Nuisances Removal Act (1854) was intended to effect with respect to the removal of nuisances, and the enforcement of regulations for the prevention or mitigation of epidemic, endemic, or contagious diseases, the same end in places not within a town, as the Act of 1851 had in places within a town, would be accomplished under its powers. Like that Act this has been more than once amended. In 1849 the only sanitary enactment was an extension of the Metropolitan Act.

In 1850 was passed an important "Act to make better provision for the Interment of the Dead in and near the Metropolis." Recognising the great truth that all interment within the boundaries of a city is in opposition to sanitary principles, it provided that when the General Board of Health, who were appointed to carry into effect the provisions of the Act, should see fit, they might report to her Majesty that interment in any church, chapel, or burial ground, ought to be discontinued; whereupon the Privy Council was empowered to empower any body having charge of such a ground to continue therein after a certain fixed period. The Act also empowered the General Board to purchase existing, or to form new cemeteries at convenient distances from the metropolis, and to give a grant of land to any such body as it might think fit; but that this Act may be ascribed the abolition of intra-mural burial, and the construction of spacious and neat cemeteries on all sides, but at some distance from the metropolis, though the actual accomplishment of the object has been much hindered. By the Act of 1852 parishes or districts willing to construct new burial grounds were empowered to elect Burial Boards, to which were entrusted the construction and management of the burial grounds, subject to the approval of the Secretary of State. An Act of 1853 extended the Act of 1852, and the Act of 1852 was extended by an Act of the same year amendment the Burial Act of 1852, and extending its provisions to any city or town in England. Another amending Act was passed in 1857.

In 1862 the object was to amend the Act bearing on the health of young persons and females working in factories,—by which, as amended in 1853, the period of labour of such persons was restricted between the hours of six in the morning and six in the evening, or during winter from seven to seven, and on Sundays from noon to six; by which the Act gives the right to the Board of Health to enquire into the state of the factories, and provides for the employment of agents to make such inquiries. Under these powers the inspectors have been extremely useful, and have enabled the Board to enforce the law in many cases in which the employers have been most obdurate.

A much needed Act was passed in 1851 for the well-ordering of Common Lodging Houses; and in the same session one for encouraging the establishment of such houses of a superior kind. Those Acts did not apply to the Metropolis, and the works of the Board were much impeded by the density of population. By the Act of 1852 the provisions of the Act of 1853 were extended to all common lodging-houses, by an additional Act in 1853. How much such a measure was required, what has been already said will have sufﬁced to show; but the power of the Board is still limited, and by the same Act is still retained in the hands of the Local Government Boards, who are hardly ever active. In Hucknall, Nottinghamshire, Mr. Lee found the common lodging-houses "hot-beds of disease and vice. . . . . . Men, women and children, and frequently dogs, form a promiscuous herd, all sleeping in the same room, from which every breath of pure air is excluded. . . . Most of the lodgers sleep in a state of absolute nudity, and decency, with the greater portion of them, has long ceased to be thought of." In one house he found, in a single room, six beds, in which were two females, and seven in the same room, in which every breath of pure air is excluded. . . . Most of the lodgers sleep in a state of absolute nudity, and decency, with the greater portion of them, has long ceased to be thought of. . . . In one house he found, in a single room, six beds, in which were two females, and seven in the same room, in which every breath of pure air is excluded. . . . Most of the lodgers sleep in a state of absolute nudity, and decency, with the greater portion of them, has long ceased to be thought of. . . . Most of the lodgers sleep in a state of absolute nudity, and decency, with the greater portion of them, has long ceased to be thought of.

In the case of the Londonнапример, the Board of Health has been enabled to extend its powers, and to secure the proper management of the establishments under its control, by the Act of 1856. This Act contains provisions for the prosecution of persons who are guilty of neglect or omission to carry out any order of the Board of Health, or to give the Board such information as it may require; for the punishment of any person for wilfully obstructing the exercise of any power under the Act; for the regulation of the conduct of persons, and for the prevention of disturbances, in the manufacture of gas, or its distillate streams below Teddington lock; are sufﬁciently referred to in the following article. [Public Improvements, Š. 2.]

In 1854 was enacted the Board of Health Reconstitution Act, and amendments of the Metropolitan Burial Act, and the Metropolitan Police Act of 1839; and in 1855 the Local Government Act of 1854 was altered and extended to all the counties, and certain amendments of the previous Act were passed. These Acts were all of extreme importance, and the last mentioned Act was especially so, as it afforded the first opportunity of extending the pow-

The Smithfield Market Removal Act of 1851; and the Metropolis Water Supply Act of 1852 (by which the water companies taking their supply from the Thames are, with the exception of the Chelsea Company, prohibited from taking any water at the point of junction of the Thames (or its orifices streams below Teddington lock), are sufﬁciently referred to in the following article. [Public Improvements, Š. 2.]

In 1854 was passed an Act which, as amended by the Act of 1857, renders it compulsory to have all furnaces employed for manufacturing purposes within the limits of the metropolis, and the furnaces of all steam-boats plying on the Thames, so constructed or altered as to consume their own smoke, a measure which has been for many years advocated by the London atmosphere. In the same year the legislature rendered the practice of vaccination compulsory.

Registrar-General in one of his valuable reports (1858), "there is room for immense improvements in the sanitary condition of the population." And we cannot perhaps better conclude a paper on the Public Health, in which the subjects have so often been dwelt on, than by quoting what he—speaking with the authority derived from a knowledge unrivalled in extent and accuracy of the sanitary state of the whole of England and Wales—"whilst asserting his belief that the mortality of England and Wales is being reduced, and that it is a national duty to use every effort to diminish it, the time has not yet arrived when the health of the metropolis, and many other public buildings of considerable size and completeness, as well as many great commercial works, have been constructed; and street architecture has assumed an entirely new character and consequence. And in all these matters the larger are the number of dwellings, the more likely are they to enter into partnership with the metropolis. It would indeed be severely an exaggeration to assert that more and greater public works have been constructed, and more public improvements have been effected during the last twenty years, than during any previous half-century.

New Streets.—The new streets in the metropolis have added much to the public convenience, and greatly improved the appearance of certain quarters; but much more might have been equally accomplished had the improvements been carried out as part of a well-considered general plan, instead of being disconnected and local experiments. In the City, however, something like a general plan has been observed. The erection of the new London Bridge led to the formation of 20 acres of new houses, which showed the necessity of still greater changes; and the civic authorities have since kept that necessity steadily in view. The erection of the new Royal Exchange afforded an opportunity for opening the area surrounding that building. By the removal of the Corn Exchange, the Yards, and the City Hall, to St. Paul's, an excellent street—New Cannon Street—has been formed from King William Street to the east side of St. Paul's Chu-chyrd. This street has been for the most part lined with large and lofty warehouses, many of them of considerable height, and has had a remarkable effect on the character of the City, and is a monument to the policy of the corporation. But the new line of thoroughfare, i.e., Gresham Street, extending from Lothbury to the Post Office, has been formed as a continuation of the same character of acceess, and has been formed for traffic as from its width and position it ought to be, it will be necessary to make very extensive alterations in the area surrounding St. Paul's Cathedral—and such alterations are equally desirable for the architectural effect of that edifice.

Another, though less important new line of thoroughfare, is Gresham Street, extending from Lothbury to the Post Office, and as a street it has been formed for traffic as from its width and position it ought to be, it will be necessary to make very extensive alterations in the area surrounding St. Paul's Cathedral—and such alterations are equally desirable for the architectural effect of that edifice.

Beyond the limits of the 'City,' the first place among the metropolis of London must be assigned to the new thoroughfares which connect Holborn with Oxford Street by a straight and wide road, which passes to the north of the old mean and circuitous way by St. Giles' Church. On the north side of New Oxford Street a few good houses have been built, but much less has been done for the architectural aspect of the street than could have been wished. In the same vicinity Endell Street has opened a way from Long Acre to Bloomsbury, and thus formed a tolerably broad thoroughfare; and, though somewhat awkward and indirect thoroughfare from the Strand to Old Compton Street, the only thoroughfare which connects Holborn with Oxford Street by a straight and wide road, which passes to the north of the old mean and circuitous way by St. Giles' Church. On the north side of New Oxford Street a few good houses have been built, but much less has been done for the architectural aspect of the street than could have been wished. High Street (opposite Leman Street) to Spitalfields Church, whence it is continued by New Commercial Street to Shore-
ditch, near the terminus of the Eastern Counties Railway; thence, with certain alterations, to Rotherhithe, opened a direct thoroughfare from the London Docks to Shoreditch. A new line of street on the Surrey side of the water, from High Street Southwark to the Waterloo Road, and others on the Middlesex side, have been authorized by the Metropolitan Board of Works, but the execution of neither of them has been commenced.

**Parks.**—The oldest of the new parks is **Victoria Park,** on the eastern side of London, which was commenced in 1833, and opened from this street, commencing westward from Bethnal Green to Hackney Wick, and is bounded on the south by Ducketts Canal. Victoria Park was laid out with more regard perhaps to convenience than to pic-
turesque effect, but it is yearly increasing in attractiveness as the trees with which it is supplied increase in size and vigour. A portion of this park has been appropriated as a free play-ground, and a free gymnasium has also been formed—both of which have proved, as well as the park itself, invaluable contributions to the pleasure of the poorer classes of the extreme east of London. **Battersea Park,** occupying the marshy tract on the right bank of the Thames, of which the notorious Red House may be taken as the centre, was commenced, after much delay, in 1854, and very much prejudiced by the invasion of the pest. It has a more ornamental character than in Victoria Park, and alto-
gether it already wears much more the aspect of a pleasure-
ground. Its area is about equal to that of Kensington Gardens. It contains a large and separate park, the near part as a sort of garden, and well stocked with shrubs and flowers; a noble river esplan-
ade, 120 feet wide, extends the whole length of the park; and the park itself is well provided with broad walks and canals. To the latter approaches. A handsome suspension-bridge gives the inhabitants of Chelsea ready access to the park. As in Victoria Park, it is proposed to build villa residences along its borders. Like Victoria Park, it has provided an agree-
able and much-needed place of open-air recreation to a very considerable extent, occupying about 233,000L. Kensington Common, which had been per-
mitted to fall into a very disreputable state, has by govern-
ment assistance been enclosed and planted. It has been somewhat absurdly dignified with the title of Kensington Park, but, though it has no claim to such a designation, it forms an agreeable pleasure-ground. The model cottages erected by Prince Albert near the site of the Exhibition of 1851, have been re-erected as an entrance lodge to Kenning-
ton Park, near the place where the residence of the Prince of Wales is situated. Mr. J. C. Loudon, of Finsbury Park, but its construction has not yet been com-
enced (May, 1855). Another park has been projected for the use of the inhabitants of the south-eastern extremity of the metropolis, and recently approved by the commissioners of the city of London, to which is added the spacious grounds of Rotherhithe and Deptford; but it is at present only a project. In the old parks many improvements have been made by better draining, the formation of new walks, the erection of new lodges and gates, the addition of numerous seats, &c. The most extensive improvements have been perhaps effected in St. James's Park; where a new broad entrance has been made between Marlborough House and St. James's Palace, and in a line with it a suspension-bridge for foot passengers (by no means a favourable specimen of that kind of bridge, however) has been constructed. New water, new approaches being at the same time formed on the other side. The lake has also been cleared, and a new bottom constructed of thick concrete, thereby at once increasing the accommodation for skaters, and affording safety for skaters.

**Architecture.**—The most important building erected in London during the period of which we are treating—the most important indeed which has been erected in London since the commencement of this street—has been commenced by the celebrated civil engineer. On the completion of the river wall, it was instructed to carry out his design. The first portion of the works undertaken was the river wall, which was con-
structed by means of a caffer dam, under the joint super-
vision of Mr. P. and Mr. C. A. Barry, and the celebrated civil engineer. On the completion of the river wall, the foundations of the building having been simultaneously proceeded with, the first stone of the building was laid, without any ceremony, by the architect's wife, April 27, 1840. The first stone was however not the last, many interruptions of the ceremonies being necessitated by the appointment and proceedings of committees of the two Houses of Par-
lament, royal and parliamentary commissions, commissioners of works, ventilation directors, and other principal and sub-
ordinate authorities, and the alterations and changes which at times made in the plans of the architect and of each other. The House of Peers, with its libraries and offices, was opened on the 16th of April 1847. The House of Commons, with its offices, was opened on the 23rd of February 1854; and on the same day all the public entrances, the great Central Hall, and St. Stephen's Hall, were thrown open—
all, like the laying of the first stone, being done without any public ceremony: but about the same time the architect was dead. On the 3rd of April, 1857, at the age of Mr. E. M. Barry, (in a paper descriptive of the new palace, read before the Royal Institute of British Architects, Feb. 1, 1858, and of which, as it may be regarded as semi-official, we have made use,) most of the remaining portions of the edifices have been completed; and to the last little remains to be done. The Speaker's House is all but
finished, and will be occupied after Easter. The residences in the south wing will be completed in a few months, and before long the main towers, the royal gallery, and the great entrance portico will be ready for occupation, so that by the close of the year the present works at the new palace will be brought to a close. Much has been said," continues Mr. Barry, "about the time the edifice has taken to construct, ... but I must say that, from my own observation, it is a work for which the public of the country has never been interrupted for an hour, but has always possessed temporary accommodation on the site, which has only been handed over permanent to the builders—architects, at any rate, will not think the time that has elapsed between the laying of the first stone in 1840, and the completion of the building in 1858, has not something to show in the work that has been done." In this observation we quite concur. The public may be to complain of, the time that has been spent on the building, the extent, character, and complexity of the works, even had there been no extraneous hindrances, would have amply explained and justified; indeed it is probable that all the time required for the completion of any very of construction, and richness and extent of ornamentation
has ever been erected in anything like so short a time.

The style of architecture adopted for the new palace is that commonly known as the perpendicular Gothic of the reign of Henry VII., but that style is chiefly known from the ecclesiastical and collegiate buildings erected in or about the reign of that monarch, whereas the architect himself says of the new palace, "it has been my aim to avoid the ecclesiastical, collegiate, castellated, and domestic style, and to select that which I consider better suited to the peculiar appropration of the buildings." The east, or river front, which stretches along the Thames a length of upwards of 900 feet, and contains the libraries and committee-rooms, was the first part of the palace ready for occupation. Of this face the central portion is a story higher than the rest, and two towers with high roofs flank each extremity. Except that the end towers project somewhat, the river front is not only uniform in character but unbroken by receding parts, "reliance being placed," says Mr. Barry, "on bringing up the sky-line to avoid monotony." Throughout this front, as indeed with scarcely an exception throughout the building, the wall-surface is covered with paneling and profusely decorated with colonnettes. The kind of columns which the river front was intended as a record in stone of English history. There are thirty-five bays exclusive of the two oriel bays; each of these thirty-five bays contains the arms of an English sovereign, beginning with William I., in the following order: 4 A 2
Arms of England, with the motto, "Victoria Regina feliciter reignas." Examine closely the effect is extremely rich, though somewhat monotonous; but the enrichment is almost entirely lost when the façade is looked at from a sufficient distance to be viewed as a whole, and this is almost necessarily the case if the House is to have any effect upon the distant or invigorated by the play of light and shadow. It is impossible not to regret that, by the adoption of bold breaks in the outline, a mere picturesque combination has not been presented to the river.

The interior is much more varied, and promises to be much more satisfactory. But for its full effect it must wait for the removal of the present most unsightly law-courts, and the completion of the architect's design by the erection of the Tower, with fan-lighted turrets at the corner of Palace Yard. The great feature of this front is the Victoria Tower, which occupies the southern extremity of the building. This magnificent structure is 70 feet square, and rises to an altitude of 545 feet to the top of the turrets, being the loftiest tower in existence.

It forms the royal entrance to the palace, the basement being a noble arch 60 feet high and 22 feet wide, under which the royal carriage passes. Triple windows of very rich and beautiful design occupy the chief wall-space of the two principal stories. The entire unpierced wall-surface of this vast tower is covered with panelling, with canopied niches containing statues of the monarchs of England, and with the arms and supporters of the different sovereigns. A pierced parapet, extending from the wall to the turrets, without the angles from the height of 55 feet above the cornice.

From the summit of the roof will float on state occasions the royal standard; and the scale on which the whole is conceived is truly magnificent. On the front of the tower the flags staff will be "of rolled sheet iron firmly bolted together, 110 feet long, 3 feet in diameter at the base, and weighing between 16 and 18 tons," while the flag, which will be 60 feet long and 40 feet wide, will have to be hoisted to its place by machinery. The Victoria Tower may fairly be said to have the finest tower of medieval date for beauty and grandeur as well as for mere size. Two other towers form equally important features in the design—the Central Tower, less lofty in itself than the Victoria Tower, but endowed with a light and elegant style, which rises to a height of upwards of 300 feet, in many points of view glooming admirably with the main features of the palace; and the Clock Tower at the north-western angle, by Bridge-street, which though little lower than the Victoria Tower, is much less ornate, being the architect's object "in designing this tower to make the clock the predominant feature: all else was to be pedestal or roof."

In the interior, the chief interest of course centres on the "Hall of Parliament." These are placed pretty nearly in the midst of the building. In the central part of the Central Hall, a noble octagonal chamber covered by a stone groined roof 70 feet in span, which forms the principal floor of the Central Hall a central arch, richly carved, leads to the House of Peers, and a similar archway in the lobby on the north to the House of Commons. The House of Peers, as the chamber in which the sovereign delivers the royal speech in the presence of the members of both houses of parliament, as well as the members of the diplomatic corps and of the royal household, is the larger and more splendidly fitted apartment. But knowing its purpose, the first emotion of the stranger is usually surprise at its apparent simplicity; its proportions are—length 90 feet, breadth and height 70 feet; windows with six or eight lights, without stained glass, on the east, and the same number on the west side, and three compartments corresponding to them in shape, but filled with pan-tiles in fresco, at the south, or throne end, and three similarly sha-ed and gilt-dome compartments at the north, or bar end. The ceiling is flat, and divided by longitudinal and transverse beams into 18 compartments, which are subdivided into panels, and these, as well the wall-paintings are of a very simple and unembellished kind; indeed every portion of the wall-surface which is not occupied by statuary, is decorated with gilding or colour; and in respect of its decoration the room is probably the most elaborate and gorgeous which has been constructed since the decline of magnificence in English architecture. The Victoria Tower is 63 feet long, 45 feet broad, and 44 feet to the centre of the present ceiling, the original ceiling being concealed by one of a different form, with a view to remedy certain acoustical defects. In character this apartment bears a general resem-

ance to the House of Lords, but it is much less ornate. Still more than that room, it wears a close and confined appearance. Indeed, though capacious enough for ordinary occasions, it is incapable of containing the entire body of members in their proper places, while the accommodation for the visitors of the House is correspondingly inadequate.

The House of Commons—the very heart and centre of legislation—is, in a legislative palace covering an area of some eight acres and costing upwards of two millions sterling, provided with a chamber no small to hold all the members; yet so ill-adapted for its object that the members can with difficulty hear each other speak, and the public reporters have constantly to note that "the hon. member was quite inaudible in the gallery." The room is however a very handsome one, though less handsome than before the alterations; and for its faulty form and insufficient size the architect is said to be not to blame, the shape and proportions having been imposed upon him by the instructions of his employers.

Connected with the houses are libraries for Lords and Commons, containing upwards of 40,000 volumes; a committee rooms (admirably adapted for their purpose), refreshment rooms, &c.; and it may be mentioned as showing the singular completeness of arrangement which modern appliances permit, that all the windows have been arranged to be openable, being either fixed, with an air-current connected with a galvanic battery, so that the principal doorkeeper is enabled to make contact and ring all the bells at once, by pressing his hand on a button attached to the arm of a chair; and thus announce to the committee of some thirty members the admission of the to the House of Commons. A royal robing room of singular magnificence has been provided by the state entrance, and from it her Majesty passes through the Royal Gallery—another stately chamber—to the House of Lords. The Speaker's House, with its noble requisites of repose and state, is in a situation remote from the north end, and there are seventeen other official residences in the building.

Of the fine arts decorations which have been employed with a liberality unknown in any other English edifice we need content to borrow Mr. Barry's brief summary. "Frederick William Greatmore, M. A., by Messrs. Dyce, Cope, Macline, and Horsey. In the upper waiting hall, river front, by Messrs. Cope, Watts, Herbert, Horsey, Teniel, and Armitage. The Queen's robing room is now in the hands of Mr. Dyce; and the Peers' robing room is committed to Mr. Herbert. Mr. Ward is also engaged on a series of pictures for the corridors leading from the central hall, some of which have already been exhibited. Bronze statues have been placed in the niches of the House of Commons, by Messrs. Westmacott, Hervey, Dyce, Cope, and Mackenzie. Lord Woodington, Timbrell, Westmacott, Thornycroft, Thrupp, and Ritchie. Large white marble statues have also been erected in St. Stephen's Hall by Messrs. Foley, Bell, Marshall, Macdowell, Bally, and Carew; and a colossal marble group of her Majesty, by Gibson, in the prince's chamber; and Mr. Macline is engaged in painting the walls of the royal gallery. The whole of the statues and carving of the exterior, were executed by and under the superintendence of Mr. Thomas; and the lower floors of the principal buildings were finished by Mr. Welby Pugin, who may account for their excessively ecclesiastical and medieval character. "The total cost of the structure up to the 25th June, 1843, during which it has been in progress, is 1,768,076l. 4s. 6d." (Barry). The estimate, however, was for 1,378,000l, but it is very evident that the contract for the work, as it was executed, has been overhauled at a very considerable cost. Indeed, it is the interest of the public that the cost of this famous building should be considered, in order to satisfy themselves whether the enormous expenditure of millions of money is not, in some degree, an extravagance. A building of this description is naturally, and indeed too evident, an extravagance. A building of this description is naturally, and indeed too evident, a subject for a public inquiry; and the public are entitled to some assurance that the expenditure of millions of money has not been ill-spent. In mere extent the building is one of the most spasons of modern structures, covering
as it does an area of upwards of eight acres, and comprising eleven hundred apartments, above a hundred staircases (some of them of grand proportions), and more than two miles of corridors and passages; while as a specimen of constructive skill it is in the highest degree serviceable to the city and to the country. We have spoken freely of what we regard as its defects as a work of art, but we gladly record our conviction that, with all its defects, it is by far the most satisfactory, as well as the most useful, public building which has during the present or the last century been erected in England, and we believe it to be the finest which during the same period has been erected in any part of Europe.

A year or two back it appeared likely that another building on a similar scale to the new Palace of Westminster would be erected, in connexion with the new palace, and worthy of that edifice, the government, having in 1856 offered premiums to the amount of 5000£ to the architects of all nations, without re-tricting them as to style or cost, for a block-plan which should exhibit the best scheme for the concentration of the principal Government Offices, on a site lying between Whitehall and the New Palace at Westminster; and also designs for two buildings which Her Majesty's Government have determined to erect forthwith, as a necessary accommodation—one for the department of the Secretary of State for Foreign Affairs, the other for the Secretary of State for War." By the specified time 218 designs, embracing nearly 2000 drawings, were sent in, and 17 of them, by French and German as well as British architects, were selected. The block-plans proposed the most extensive, and in fact impracticable, re-arrangements of the site; the designs extremely magnificent but quite practicable buildings. On all hands it was agreed that the successful (and some of the unsuccessful) architects would have done well to listen to the practical knowledge, taste, and power; and that the competition was by far the most successful of any of recent years. In the House of Commons, however, there appeared a very natural disinclination to procure government for so large a cost, and costly a scheme, and without any public intimation, the Lords of the Treasury have cast aside the designs which they had induced the profession to prepare on the implied understanding that the work should be given to the successful competitors, and in place of the best proposal for the New Palace Hall as commission of public buildings, directed a non-competiting architect to design a new War Office on a more limited scale. Happily the transaction has been made public before the works have been actually commenced, and it is hardly conceivable that so great a scheme, and on such a site, can be permitted in now that its real character is understood. We therefore still have hope that whatever be the size and character of the buildings decided on, it will be referred to the premised competition of the British architects; and that their exertion will not be in vain, but that the government will permit their execution unless they be found unsuitable.

Next to the new palace at Westminster, the most important recent architectural work is the British Museum, of which the architect was Sir Robert Smirke, R.A. This building was begun in 1816, and the portico was completed in April 1847; it was not however opened throughout till 1851. "The building itself is the largest and most imposing example in the metropolis of the Grecian Ionic order, and the exterior has a certain monumental grandeur of character not inappropriate to its purpose. The interior few have been found to admire, either aesthetically or for its adaptation to the object for which it was designed. Even before it was completed it was found to be too confining a hall. The Great Court of the Houses of Parliament would, was designed, and it was pointed out that "the building is therefore fortunately wasted [by the great inner quadrangle] would have provided accommodation for the whole library, much superior to what is now proposed to afford it. A reading-room makes a very insufficient accommodation for books, communicating with each other, and lighted from the top: and the writer, Mr. Thomas Watts (now one of the superior officers of the Museum Library), goes on to show in detail that the existing accommodation has been misunderstood over Sir Robert Smirke's arrangements for the library and reading-room in the new building. But so much care and money had been expended on the architectural features of the great quadrangle that it might seem barbarous to propose filling up the space," Mr. Watts suggests as another, and perhaps more practicable plan, for obtaining the requisite additional room, to remove one side of Montague Street and Montague Place and make an extension of the building on the eastern side of the quadrangle, for which the necessary arrangements were to be executed as "occasion shall arise." This latter plan is the same in principle as that officially proposed to the Treasury on the part of the Museum Trustees in March 1858, but afterwards shelved, in consideration of the scheme for the New Palace of Commons for 1853 (except that Mr. Watts proposed to afford accommodation to the chief learned societies, on condition of their collections being opened to the Museum visitors); as the former is in principle the plan which was proposed on the rejection of the quadrangle extension in 1832, by Mr. W. H. Adam, as out in the new Reading Room. Some years later Mr. Hawkins of the antiquarian department in the British Museum proposed to erect a Board-room for the trustees, with study-rooms for the chief of departments, offices for clerks, &c., in the centre of the quadrangle, connecting them by corridors with the galleries of the building itself. Mr. Hocking, the first professional architect who appears to have taken up the subject—laid before the Commission of Inquiry into the constitution of the British Museum in 1848, and before the Museum Trustees in November 1849, a plan for erecting within the quadrangle a modified or somewhat reduced copy of the Pantheon at Rome, or in other words a cupola-covered rotunda, 120 feet in diameter, and 120 feet high, "to form a grand central space of important dimensions, in which the most important works of sculpture, and of such other objects proper to the purposes of the museum as most require that steady and equable light which is so well obtained from the eye of a cupola, could be placed, and thus the corridors and galleries," as his project did not meet the very many oppositions which it encountered. In 1849 Mr. Ferguson published a plan of a building within the quadrangle to be used as a reading room and for library purposes; and in 1853 Sir Charles Barry, by direction of the government, designed extensive alterations in the museum buildings, the chief feature of his design being a grand central hall within the inner quadrangle; but neither the voluntary, nor the commissioned design was destined to be carried into execution. Mr. Panini, now principal librarian, is the keeper of printed books at the museum, and has pressed on the trustees the necessity for providing additional room for the library, and laid before them a plan for obtaining a reading room and space for a large number of additional book-shelves within the quadrangle. In 1853 he proposed a more elaborate scheme, and this on the recommendation of the trustees, the government sanctioned. His plan, as put in working form by Mr. Sydney Smirke, was to erect within the inner quadrangle of the museum a Reading Room, circular in plan, covering the space from the first to the second floor; and on the first floor to be a large portion, if not the whole, of the printed books in galleries surrounding this great central apartment. This building, of which Mr. Sydney Smirke was the architect, was commenced in March 1854, and opened for the use of readers in May 1856. The building is a hall with a cupola, and a dome, 106 feet high, supporting being cast-iron piers, which carry girders of wrought iron strongly tied together, and these bear the dome. Between the main ribs are brick arches, but the frame-work is of iron, and hence an immense saving of space is effected. The Reading Room is 140 feet in diameter, and 106 feet high, exceeding therefore in diameter every other dome in Europe, except that of the Pantheon at Rome, which is 143 feet in diameter. But it differs from the Pantheon greatly in its proportions, being circular in the greatest diameter only; lighting, the Pantheon being entirely lighted by a circular opening at the top 28 feet in diameter, while the Reading Room has a similar light at the top 40 feet across, and 20 large windows in the half of the dome. Little is seen of the exterior, but the interior proportions are admirable, and in its height, and it answers the purpose for which it was erected admirably. It affords ample accommodation for 300 readers, for whose comfort and convenience abundant provision is made, of which the most remarkable is the pleasant light which fills the room, being 80,000 volumes: in the connected galleries and passages there is shelf-room for above a million volumes; and the whole arrangements afford an example of ingenious contrivance, as the building itself is a fine example of constructive science. It is at present the most public building in England, and in the inside within the last few years. The front of Nash's Palace is now concealed from the public eye by a new façade designed by Mr. Blore. In magnificence it is however greatly inferior to Nash's façade, but as that was in
most respects. The new front merely suggests the idea of a "terrace" of a rather superior class of private residences; and the original poverty of character has been increased owing to the circumstance that the stone selected was of so friable a nature that it could only be opened by a few small decays, and it afterwards covered with paint. The Marble Arch too, which, however inconsiderable with the palace, assisted in imparting to it a certain dignity of appearance, has been removed; and now forms the front of the old Clapham, Hyde Park Chapel, and is destined to meet the congestion of 19th century Gothic architects—forced thereto probably in many instances by their clerical employers—have sought chiefly to produce a building which should faithfully accord in general form, as well as in the window—inset, carvings, and other details, with the general style of the ancient successors,--"Decorated," or "Perpendicular" period; and it is not too much to say, with very little regard to the actual forms of worship and requirements of a church whose peculiar system of prayer and preaching was modelled on these of these styles of architecture had not merely ceased to exist as a vigorous living reality, but had perished with the season and the order of things to which it belonged. The merit of the majority of recent churches lies therefore in their picturesque quality, and some effort to produce an external form, and, in the best of them, in the sober "religions" splendour and impressiveness of their interior. There is abroad however a longing for a more perfect adaptation of ecclesiastical buildings to their actual use, a more thorough application of the discoveries of modern science, and especially of the leading men in this growing desire to cast off the merely servile adherence to mediæval precedent: the return, in a word, to the mediæval spirit—to earnestness and truth of purpose, and freedom of thought. And this has already affected much improvement, and will be still more evident if it can be shown that it is not only desirable, but also possible, were it even desirable, to particularise them, and it will be sufficient, in order to avoid invasions of distinctions, to refer as characteristic examples to the church of St. Stephen, Coleman, London churches of St. Stephen the Less, St. James, Bow, St. Etheldreda, St. John's Wood; and to the Baptist Chapel, Bloomsbury.

Of recently erected places of public entertainment, the principal is the new Opera House, Covent Garden. Covent Garden Theatre, built by Sir Robert Smirke in 1808-9, after competition with the Brunings, has been much improved by Mr. E. Barry with special reference to the production of modern English drama, and in 1846 the interior was entirely remodelled by Mr. Alban, to adapt it to the service of the Italian opera. But it met with the usual fate of theatres, being destroyed by fire March 6, 1866. For a time it seemed probable that it would not be rebuilt, but the obstacles were ultimately removed, and a new theatre is rapidly advancing towards completion, which has been designed by Mr. E. Barry with special reference to the exhibition of modern English drama, and in 1846 the interior was entirely remodelled by Mr. Alban, to adapt it to the service of the Italian opera. But it met with the usual fate of theatres, being destroyed by fire March 6, 1866. see a great deal too much flimsy 'compo' ornament—is a
Hexastyle Corinthian portico, 68 feet wide, and 80 feet high:
the columns being 3 feet 8 inches in diameter, and 37 feet high.
Flaxman's bassi-relievi, which were saved at the fire of the old theatre, have a place in the new portico, and its statues of tragedy and comedy in niches on either side of it. The basement or lower story of the portico is intended to serve as a carriage porch, while the principal story will serve as a promenade, the entrance to it being from the crush-room. It is announced that the house will be opened in the course of the present year, and that a temporary or 'floral arcade,' of glass and iron, 210 feet long, 80 feet wide, and 60 feet high, is proposed to be built alongside of it, to be employed as a market for choice flowers by day, and as a provision store for the house by night.

The increasing passion for music has also led to the erection of three or four large music halls—to say nothing of as many 'music and supper halls' for a less refined auditory, but which in size and style of decoration would a few years back have excited little admiration if constructed in those aristocratic circles. The first of the former kind, St. Martin's Hall, Long Acre, built primarily for the use of Mr. Hallah's music classes, was first opened in 1850, but only fully completed in 1853. The great hall is 121 feet long, 35 wide, and 40 feet high. In the same block, situated facing the Piazza, Sir William Pulteney Smith's magnificent edifice was erected. The whole story of this building was designed by Mr. W. Westmacott. In form and general appearance it has been modelled on the old baronial hall, though a handsome and well proportioned room, it wears too sombre an aspect to be of much artistic pretensions. A notable feature of the interior is the spacious picture gallery, with loggias, 110 feet long, and which, as the house is to be a public, or rather private factory, would be in every way worthy of its magnificent contents. Scarcely less palatial in scale or style is Dorchester House, Park Lane, erected in 1858-59 for Mr. S. Holford, in style it belongs rather to the Italian than to the English renaissance, as represented by Inigo Jones, than to the Italian adopted by Barry; and in many respects it is hardly so satisfactory, but it is a stately and imposing structure: its dimensions are 135 feet by 105. The mansion of Mr. H. T. Penrose, built by Pugin, has the Gothic revival designs of M. Dalou, at a cost of 30,000/. also deserves a word of notice, though in an artistic point of view it cannot be considered a happy effort. Like the mansions just noticed it is fitted up with great splendour, and like them it contains a singularly choice collection of pictures, and the finest collection of works by the Dutch and Flemish masters in this country.

Turning to 'The City,' we are at once struck by the great improvement in the ordinary street architecture, which is still more distinctly manifested than at the west-end, though at the west-end the improvement has not been incon siderable. In the new streets have sprung up a long succession of warehouses of a size and coldness quite un precedented in London. Many of them are faced with stone, decorated with carving, and make considerable architectural pretensions; and all are built in a style of construction at once bold and substantial. The most striking feature of these new buildings is the great variety of their form, five, six, and even seven stories being far from unusual. Of these warehouses the most noticeable are those in New Cannon Street: and its vicinity, Wood Street, &c.; but piles of 'offices' of almost or quite equal magnitude have been built, or are building, in every part of the city which lies within the business boundaries, in the narrowest alleys, courts, and lanes, as well as in the main lines of traffic. The most remarkable of these blocks of offices for extent is one which is impossible for an architect to look at without a certain feeling of horror and disgust. It is a most hideous specimen of that sort of architectural art which is practised in the city, and the grandeur of mass, and greatness of manner, combined with simplicity, it surpasses everything else in the metropolis.

Unfortunately on the removal of the Excise department no other use was found for it, and it was destroyed to make way for a building of about the same dimensions as the former, and a greater number of separate offices than any other in the kingdom.

Another class of city buildings which has done much to raise the character of London street architecture is that which includes the office buildings on Broad Sanctuary, which by Sir Robert Smirke, has been made to give place to a much more ornate façade by his brother Sydney. This, however,
opposite to each other in Threadneedle Street, the Australian Bank by the Royal Exchange, and several others of more or less architectural pretensions; and among them must now be placed the well-known South-Sea Bank. This was completed in 1808, at a cost of £100,000, and the bank had eminence as the corporation for which it was originally built—the Royal British Bank. Among private establishments may be named that of Jones, Loyd, and Co., in Lothbury, whose new office, by the remodelling of a former building, was completed in 1813. In many cases in this connection refer to the as yet unfinished offices of the National Discount Company in Cornhill, which is a work of unusual florid character, as well as of considerable size—but the ornament is mere stucco, and the whole affair looks rather like an immense potsherd. The Pantheon and the Pantheon Hotel, now the best of the recent city insurance offices are the Sun (by Mr. Cockerell), in Bartholomew Lane, and the Imperial in Threadneedle Street: the latest are the Royal, in Lombard Street; the Union (a substantial hut rather plain building) in Cornhill the Crown, with some piquant Byzantine features, in Bridge Street; and the Law, in Chancery Lane.

Some of the City Companies have also built new halls, or put new fronts to their old ones. The largest of the older City halls, the Merchant Taylors', in Threadneedle-street (erected by Jarman after the fire of London), has been concealed from view by a screen of offices of no great elegance built by the company. The Weavers' Company have built themselves a new hall in Basinghall Street—a substantial structure, but deformed by a misdirected and over-elaborate scroll. A rather similar structure to offices. A somewhat better building is Dyers' Hall, Dowgate Hill, (by Mr. Corbett); but, like the companies just noticed, the Dyers have combined profit with display, having also thrown a couple of extra storeys to make a large banking-office to contain offices. The Clothworkers in their new hall, in Mincing Lane,—now in progress, from the designs of Mr. S. Angell,—have been less thrifty. Their building is wholly appropriated to the purposes of the company, and it is a very costly, as well as a substantial edifice. The façade, which is of Portland stone, is Italan, of a somewhat florid character, and, like the interior, it is much enriched with carving. The chief feature of the interior is of course the great cornice, which carries the whole portion of the building to the mezzanine offices. The Clothworkers in their new hall, in Mincing Lane,—now in progress, from the designs of Mr. S. Angell,—have been less thrifty. Their building is wholly appropriated to the purposes of the company, and it is a very costly, as well as a substantial edifice. The façade, which is of Portland stone, is Italan, of a somewhat florid character, and, like the interior, it is much enriched with carving. The chief feature of the interior is of course the great cornice, which carries the whole portion of the building to the mezzanine offices.

In shop architecture the City has also of late taken the lead. A very recent example—a silversmith's shop in Cornhill, which is the Exchange, is in my opinion the finest and most pretentious specimen of shop architecture in London. As an illustration of the tendencies of London shop architecture in the last thirty years, and the influence of the Exchange, the shop is a most interesting and instructive example. The Exchange, though not more than 40 feet wide, rises to a height of about 100 feet. The shop is 26 feet high, and the whole of the front above it—of Bath stone—is carried on a wrought-iron tubular girder, which is borne (or seemingly so) by red granite pillars having Corinthian capitals of Bath stone. The upper part, of four stories, has attached Corinthian pillars of polished granite; a balcony at the fourth story; and crowning the summit a very bold cornice. The style is Very correct, and a great deal of ornamentation is everywhere introduced. In fact, a description of the whole building would be an exhibition of the statement of the story. The space between the arch of the shop-windows and the cornice above is of statuary marble, carved in a bold and florid style by Trenantova. On the whole, the façade has a rich and striking character, with an allowable excess of ornament, the chief defect being the appearance of weakness, arising from the want of sufficient apparent support in the ground story for the enormous mass of Ist. The disagreeable aspect which a building so narrow, as compared with its height, necessarily has, is removed by the house on each side being built of a uniform height, though somewhat lower than the central building, and in a similar though much plainer style, though, of course, it partakes of the support but being plainly subsidiary to the central compartment. The interior of the building is even more ornate than the exterior. The ground floor is open to the room above, around which runs a broad gallery supported by coupled Doric columns, over which are coupled composite columns with shafts of coloured marble. The ceiling, like the gallery, has deep and richly ornamented coffer, the beams being supported by coupled carayaltic figures. From the window of this gallery a view can be obtained of the profusion of coloured marbles, carvings, looking-glasses, and decorations, with the glittering stock rather dazzling than satisfying the eye. Such a building as this, with all its faults, shows of how much consequence shop architecture is to the accommodation and comfort of the public. It may perhaps be said that the abilities of architects of artistic tastes, constructional knowledge, and original fancy. By Mr. Rees' and his followers shop architecture is denounced in unmeasured terms. But shop forms of necessity the greatest space being the whole, and the shopkeeper in such a city must endeavor to render their places of business as attractive as possible. If houses are to be built expressly for shops, there can be no good reason why architects should not construct them as ornamental and beautiful as possible, and as is consistent with the purpose for which they are designed. In the great majority of recent shops everything else has been made to yield to the desire for as large a surface of plate-glass as possible; and hence what was indicated as the most palpable fault in the shop front just noticed—the want of sufficient apparent support in the ground story for the floors above—is the almost universal defect in the showier class of such buildings: and it is a fault fatal to all architectural effect. It is the excess in the height of the Exchange that makes the whole upper part of the house rests on a heavy carved cornice, and this, with that which it carries, on two immense sheets of plate-glass. Yet, if possible, the absurdity has been rendered even more palpable by the churchyard which has been made into a garden by throwing two or three houses together, is made in appearance to bear the whole superincumbent mass of brickwork upon a few slender glass pillars, and even the wider attached pilasters at the end are covered with looking-glass. The case of course in all these cases is the same. The supports are really supported on wrought-iron girders, and for bearing these sufficient provision is made by strengthening the side walls, and by adding piers, &c., where necessary. Now, conversely, it is the appearance which is to be considered. It is the eye by giving to the shop front an arched form, and thus inducing the appearance of sufficient support for the upper stories—a method which the shopkeeper will not in many instances allow, and when he does, will probably shorty destroy the effect of by some gaudy decorative additions—why not accept the necessities of the case, and endeavour honestly to surmount them? Railway and other recent engineering works have too much accustomed the eye to the girder for its vast strength to be for a moment questioned the view of the whole street, and the Exchange is at last but a part of the great building, and its supports be satisfactory, there will be no doubt—one of the latent doubt even which unconsciously produces the feeling of distrust in the un instructed observer.—of the sufficiency of the supports of the building. What seems to be wanted, then, is to frankly admit and not to endeavour to conceal the girder form, and to give to the supports the greatest possible emphasis. Then trinial, equally with circular or pointed arches, architecture will be found to satisfy the eye as the primary essential of security, while it alone can be found adequate for the varied requirements of the London tradesmen of this present century, as it alone can, within due limits as to altitude, securely bridge over wide spaces. It has the advantage of giving a better opportunity of afford ample scope to the architect's inventive skill. Where a very wide window surface is not required, a different method of treatment is applicable; and the stationer's shop at the corner of Chancery Lane is a favourable example of what may be done under such circumstances, and a sufficient illustration of the opportunity which shop architecture affords for architectural taste and ingenuity; and also, we may remark in passing, a satisfactory illustration of the great rectitude in London of the current tendency to adopt at one and the same place an adjacent to well-executed brickwork in London street architecture, when it is used as composition and not as a deceptive imitation of stone.
facade certainly improved its general character; and Newgate prison, of which the whole interior has been rebuilt on a very superior plan, while the exterior—a classic example of prison architecture in general estimation—has with excellent taste been left in its present state. It is associated with Newgate in the architectural mind, as being by the same architect, Dance, very similar in design as well as purpose, and its near neighbour, Gibsop-street Compton, has however been less fortunate, having been pulled down when the street was widened; the site is still unoccupied, as is also that of the Fleet prison, pulled down in 1844. The new City Prison at Holloway is an extraordinary looking castellated pile, of great size and expense, and was for a long time the object of much sanitary and healthful place inside. Two or three other prison-palaces have been constructed within the last few years for the care of metropolitan rascals: the chief being the model prison, Bentonville, and an enormous structure on Wandsworth Common. Of semi-public and corporate buildings outside the city walls a few must be noticed. Lincoln's Inn Buildings, of which the first stone was laid by Vice-Chancellor (now Lord Justice) Knight Bruce, April 20, 1843, and which were inaugurated by her Majesty, October 30, 1846, form one of the most striking and picturesque of the recent buildings of the metropolis. They consist of a dining hall, a library, and a benners' dining and council rooms, needless by a handsome vestibule; the architect is Mr. H. H. Peto. The buildings are both in the Tudor domestic style, and are constructed of red and black bricks, with stone quoins and dressings—the whole being executed in the best manner. The dining hall is 130 feet long, 45 feet wide, and 64 feet high, with a handsome barrel-vaulted ceiling; and the outer facade is of five large and handsome windows on each side, two large windows at the eave, and a noble window of five lights at the opposite or south end. All the windows are enriched with heraldic emblazonings, the pendants of the roof are gilt, and the front of the building is adorned with sculpture: on the whole it is undoubtedly the finest room of its kind in London—we are of course not comparing it with Westminster Hall, which is wholly different in character. The builders and company who have designed this very handsome room,—80 feet (or including the orielis 90 feet) by 40, and 35 feet high—its chief features being an elegant semi-octagonal arch at each end (like the windows in the hall enriched with stained glass), and an oak roof of good design; as a reading-room it is comfortable and even luxurious in its arrangements. In the Temple, New Buildings, somewhat similar in style but less imposing in intention and effect, have been erected by Mr. Sydney Smirke, R.A. With these we may place, as californian in style though not in object, University Hall, at the back of University College, by Professor Donaldson. The Abbey Buildings, Dean's Yard, Westminster, require special mention as a very admirable though not serviceable building, the design of which is due to Mr. Gilbert Scott, whose recent advocacy of a free adaptation of Gothic "as the basis of future development" in English architecture has attracted such very general attention. The Bromptom Building for Composition (by Francis) is of large extent, and the design of Mr. L. E. Pearson. Lamb. The Small Pond Hospital, near Highgate, is admirably situated, and has some good features; and something similar may be affirmed of the Convalescent Hospital at Walton. The great extent of the city of London has necessitated its being judiciously placed in healthy sites at a little distance from London: such are the Working Orphan school, a large Italian edifice on Havercost Hill, the Orphan Asylum at Wanstead, the Royal Patriotic Asylum at Wandsworth General Hospital, in Ashberry, Middlesex, the Asylum of London Orphans' at Brixton, the City Industrial Schools, at Peug, the South Metropolitan Industrial Schools, at Sutton, Surrey, the Whitechapel Industrial Schools at Forest Gate, Essex, and many others. London is indebted for some recent additions to its architecture to railway progress. The new terminus of the London and North Western Railway, by Hardwick, is really a very fine and costly structure; its expense was about 150,000/. Scarcely so much is the case with the terminus of the Great Western, as it is rather remarkable as an engineering than an architectural work, but it has the superior merit of showing adaptation to its purpose in a very usual degree, and, to our thinking, is consequently the most satisfactory of all the London termini; it was the joint production of Messrs. Brunel and Digby Wyatt. Adjoining it is a hotel built for the railway Company by Mr. Hardwick, which is in size, architecture, and comfort, surpasses any yet constructed in London. The style—late French renaissance, with its bold mass of roofs to the centre and turrets, the colossal terminal figures supporting the arches of the main entrance, &c.—is a novelty in London, and altogether it excited much notice. The terminus of the London Railway, at King's Cross, by Mr. L. Cubitt, merely presents, externally, brick terminations to the carriage sheds, with a lofty central tower; but inside the vista formed by the sheds and offices is magnificent. The London and South Western Railway Company have built an hotel rivaling in size that of the Great Western: like that the style is continental, but rather strange than beautiful. None of the other metropolitan railway termini of recent erection have any architectural character. Though we have left ourselves no room to describe, we must just refer to the great works completed and in progress in connection with the docks of London. Of those of the Metropolitan Waterworks, the most extensive is the works of the London Docks at Shadwell, to way for which many hundreds of houses have been removed. The object has been to afford greater facilities for the admission and unloading of the immense vessels which the requirements of modern commerce have called into existence, as well as to obtain improved room for general purposes. With this view new basins of great depth have been formed, a new entrance constructed, with gates of enormous size, and various hydraulic and other appliances added of great power, as well as new wharves and other works. At the Commercial Docks, on the Surrey side of the Thames, extensive alterations and improvements have been carried out. On the Philo, or Marshes, just below the Blackwall, have been formed, on the site of the once famous, which affords at present about 90 acres of water area, with entrances admitting larger vessels than any of the older docks, though not, we believe, larger than the new works at the London Docks mentioned above. At Woolwich, a steam dock has been constructed, and vast works of various kinds erected, in connection with the arsenal, foundries, steam factories, &c., of the Government. And, finally, at Brentford a large new dock has been constructed, chiefly with a view to afford increased facilities for water carriage in connection with the Great Western Railway. A few words on some of the larger works resulting from the progress of sanitary reform will conclude what we have to say respecting the public improvements of London. After the mid-19th century, corporal diets for the working classes in London were the result of the sanitary reforms of the 1850s, to remove their sordidly cherished Smithfield market; but it is due to them to say, that when compelled to provide a new cattle market in the suburbs instead of in the centre they have done what was right, and that the houses, to which the site chosen was an elevated and very convenient one, the notorious Copenhagen Fields, adjoining both the Great Northern and North London Railways. The market covers an area of about 35 acres, but a large space is reserved for cattle, and for extensive buildings for the sale of meat at a future time if it be found necessary. The provisions for the comfortable accommodation of the cattle have been made in a thoroughly humane spirit, and, in fact, whatever forethought or foresight in the evil day have been the result of large cattle markets has been done with a bold disregard of expense, which only a corporation wealthy as that of London, content
to look to a somewhat remote future for repayment, could have ventured upon. Though it is rather on account of its skilful arrangement and adaptation to its special purpose that the Metropolitan Cattle Market is to be regarded, yet it is made, as it were, a part of the architectural arrangement of the Cattle Exchange, its banks, and one of the offices are in very good taste, and its lofty central tower forms not only a prominent feature in the landscape for many miles northward, but gives an air of completeness and unity to the whole design. The Great Metropolitan Drainage Company, with the details of its arrangement, is due to the city architect, Mr. Bunning, who also, two or three years before, had rebuilt Billingsgate Market in a very skilful manner, and with a special regard to convenience, cleanliness, and propriety. But the most important and rendering it unlawful for any water-company drawing its supply from the Thames, to take such supply after a certain day from any part of the river below Teddington lock. The several companies accordingly at once set about the construction of very extensive works, the Grand Junction, the West Middlesex, the Vanxhall, and the Southwark, at Hampton; the Chelsea and the Lambeth just above Kingston. The works at these places are some of them, on a magnificent scale, the entire new works, for example, of the Chelsea Company, rendered necessary by the Act, have cost 430,000. The water is conveyed from Hampton and Kingston, in mains of from 30 inches to three feet in diameter, to the reservoirs of the several companies in the suburbs of London; and the companies are passed under the Thames at Richmond by means of the coffer dams; those of another company are carried above the bed of the river, near Putney bridge, on piers formed by Mitchell's screw piles. But even more extensive works have been the new works of the Chelsea Company, who, in works near the head of their river (including the drainage and diversion of the sewerage of the town of Herford), in forming capacious new reservoirs, and covering their old ones, &c., has expended considerably over half a million. Very extensive new works, and alterations in existing works, have also been carried out by the East London, the Kent, and the Hampstead companies.

The result of these vast operations has unquestionably been to increase the purity and quality of the water supplied to the inhabitants of London. The Registrar-General, in his Report on the Health of London for the week ending April 17, 1858, says that the London water "contains less than half the previous amount of impurity. A gallon of water of the Chelsea Company formerly contained from 37 to 66 grains of extraneous matter; the Southwark water contained from 23 to 73 grains; while the analysis now shows that only 21 grains of extraneous matter are contained in a gallon of water of the whole company. In several of the other companies a still smaller quantity of extraneous matter is found (in the West Middlesex only 17-64, in the Grand Junction 17-76 grains); but then the water of those companies was always purer than that of the first. They have, too, been more economical and costly an alteration was rendered compulsory,—the legislature might not well have gone further, and prohibited the use of the Thames at all for the purpose. For before it has reached the place where the supply is now drawn, it has been polluted by the drainage of Windsor, Chesham, Staines, and other towns, and, as Mr. Ranger, the Superintending Inspecto\r of the General Board of Health, has pointed out in his recent Report on the Sewerage, &c., of Aldenham villag...
Cockerell, may not only be fairly placed in comparison with any similar building in London, but without hesitation be pronounced in many respects the finest, as it is undoubtedly the richest, recent example of a Romanesque-Gothic edifice in the kingdom. The hall itself, 168 feet long, 100 feet wide, and 80 feet high, is spanned by a vaulted roof, and forms one of the noblest public halls we possess. The rooms devoted to the assize courts are not so satisfactory. The exterior has, at the south end, a Corinthian portico of grand proportions, with a pediment filled with sculpture; a semicircular niche with a statue of Edward I., and a niche in each story of sixteen columns without a pediment at the side. It is not impervious to criticism, perhaps, but undoubtedly St. George's Hall is one of the great architectural works of the day. The Continent has acquired a Colledge Institution, a large and handsome Tudor collegiate structure, also by Mr. Elmes; the Sailors' Home, a spacious Gothic building by Mr. Cunningham; the Branch Bank of England, by Mr. Cockerell, &c., but perhaps the most characteristic of the new buildings of Liverpool are the extensive and costly piles of offices, which are as much superior to similar buildings in London as the Manchester warehouses are to the warehouses in the City. The Docks of Liverpool, with vast ranges of connected warehouses, have been increased in size by the erection of a range of buildings of millions sterling, and are now probably unrivalled. The floating stages on the Mersey, for landing from steamers, likewise claim a word of notice: one, at Prince's Pier, finished in 1857, is 82 feet in diameter, has a capel, or chapel, of 40 feet by 140,000/. Liverpool is one of the towns which has provided itself at a great cost with a supply of pure water from a distant source. Whether as a rival or an adjunct, its neighbour on the Cheshire side of the Mersey, Birkenhead, cannot be regarded as in danger. The Docks of Great Liverpool are the Docks of the world; and by the addition of not much little addition to its existing architectural treasures, are restored and re-edited its old ones. Many of the new works are of great beauty and richness, as could not indeed fail to be the case, for they arose out of the promptings of a zealous and enlightened body of Government, and from the spirit of no niggard-hand was entrusted to architects already famous for their peculiar devotion to this branch of the art. It is, perhaps, not too much to say, that some of the new works are very strongly inside the glorious structures which surround them. But we would pay the highest praise to the so-called 'restorations.' They may have been well done professionally: they may have been correctly performed according to ecclesiastical conceptions: but the buildings which have been, restored are not now the buildings we knew a few years back, venerable in their hoary and unmistakable antiquity. They have been, too many of them, made to wear the gay drapery of youth upon the seared and bending frame of age. They now consequently exhibit either the solemn majesty of the one, or the lightness beauty of the other. Our ancient Gothic structures,—marvels in the grandeur of their forms, in the evidences of mental power and artistic fancy, in their quiant carvings and playful combinations of the beauty of line and love to longer,—structures on which the cultivated and the untaught alike swoon in awe and wonder and endless admiration,—ought only to be touched with a reverential hand. Our fathers, bowing before the sovereignty of the Greek and Roman, regarded our glory in the heights and meaner parts of our built productions of a dark age and a Gothic understanding; and they altered, improved, or destroyed them with almost equal indifference. But their contempt was, we cannot but think, less dangerous than our too ardent love. They thought it no vanity to spend time over the structures of the dark ages, when they could study the temples of the brightest days of Greece and Rome, or of those enlightened times when the lore of antiquity was restored to the scholars of modern Europe. They were already adorned by the decay of modernism, and in our foolish fondness have sought to restore them to their old beauty. All which we have replaced was the only true one—that we have indeed copied, but in copying have destroyed it. Re- translation in truth is for the most part a mistake. Ancient buildings regarded as works of art are to be preserved—like all other ancient structures, historically and for their light on the life of the people of the modern artist. If anything can be done to arrest their decay, well: but it must he so done as not to remove, if possible, a hair or a finger-nail of the original—assuredly not to substitute for its decay. For it is clear that, if we are to take in what the chipped and battered fragment we have removed was in its pristine condition. As well might the Thebes or Ithysus in the British Museum be submitted to the 'restoring'
chirol of Westminster or Bally, or any other living Philale, as our cathedrals and colleges are subjected to the tender merci

...of modern representatives of the ancient builders. We are not, of course, objecting to necessary repairs, or even, where impracticable, to rebuilding, but simply to the destructive process of thoughtlessness, the rest of our present course of teaching — the attacks on the character — the character of the old art, and replacing them by new work intended to represent (and therefore to form a deceptive imitation of) the old art on a large scale.

Cambridge has proceeded somewhat more slowly of late than the sister university with its mediæval reproductions and restorations, but it too has made a real architectural advance. Such works as those which in the first quarter of the last century, while the society of the old mediaeval idea were still enthusiastic gowmen, would now excite a shout of universal execration. But Cambridge retained longer than Oxford her love of the classic orders; and some of her latest works of that kind are of a very superior character — as the library by Cockerell, and still more the Fitzwilliam Museum, a work of much beauty and stateliness. But not to dwell longer on particular towns, we may point to the number of the different kinds of public buildings which have been erected in every part of the country as the best evidence of the reality and extent of architectural progress. In ecclesiastical edifices the progress has been something wonderful. During the last twenty years churches and chapels have been built by the thousand, and a very large portion of our ancient and picturesque churches have been repaired, or as it is termed 'restored.' As in London, so through the country, all the recent churches have been mediæval in character; indeed, as Mr. Scott observes, there are few instances of this in one of his recent contributions to the literature of Gothic architec

...neighbourhood justify the appeal. We feel safe therefore in saying that the public feeling for church architecture, and the public wish for church extension, are deeply rooted as well as widely spread, and that great as has been the progress of church building and church architecture during the twentieth century, so great will it be in the next. Twenty years will see a yet greater extension of the one, and we earnestly hope a great advance in the other.

As may be supposed from the character of the revival and the faith of one of its earliest, ablest, and most active champions — Welsey Pugin — the Roman Catholic body have fully participated in the Gothic movement. Indeed some of the finest and richest of the recent specimens of Gothic have been the Roman Catholic cathedrals and churches at Bir-

...reformed clubs, a number of significant examples would still very numerous have been the dissenting churches built within the last twenty years, and not a few of them have been of spacious dimensions and of considerable archi-

...the greatest proportion of instances of old rebuilding, and among the Independents — who have taken the lead in the chapel building movements — the Gothic style has been adopted in the great majority of instances; so it has, though not to the same extent, among the Wesleyans: the Baptists have come more slowly; but after a time the United, who have adopted the classic; the Quakers as of old repudiate altogether: but all build where they can find opportunity and means, and all build in a far superior manner to that in which they built thirty or forty years ago.

Among the general features of the period of which we are treating, a place alongside the extraneous church-extension movement, and accompanying revival of Gothic ecclesiastical architecture, must be given to the parallel ex-

...of sixty of the educational establishments of a superior class, and the revival of the old collegiate style of building. Not to speak of what has been done in college extension and new building at Oxford and Cambridge, at Eton, Harrow, Rugby, &c., we can but mention, as among many, such magni-

...by Mr. Wilson, at St. John's, Hurstperpoint, Sussex, by Mr. Carpenter; at Cuddesdon, near Oxford, by Mr. Street; the Laneadowne College, at Bath, by Mr. Wilson; the Wellington, at Sandhurst, &c.: theological institutions belonging to the Independent sect at Birmingham, at Mr. Medland, Irwin, New College, St. John's Wood, by Mr. Emmett; and at Spring Hill, near Birningham, by Mr. James—all spacious and handsome edifices in the Tudor collegiate style; and the institutions in connection with the Wesleyan movement at the Wesleyan College, at Richmond, Surrey, by Mr. Trimen; at Taunton, by Mr. Wilson; and the school at Kingswood, near Bath, by the same architect.

...n by a larger or smaller extent of ancient examples, who have not resorted to altered forms of worship and modes of thought, has the double disadvantage of curbing the genius of the architect, and of preventing the erection of an edifice designed with a single eye to its use and character. Many of the recent churches are however — with the qualific-

...in the case of the new church at Doncaster (rendered necessary by the occupation of the old church) a strong appeal to a wider public is sure to meet with a cheerful response, if an announcement can be made that the building is to be a magnificent work of art, or the exigencies of the neighbourhood justify the appeal. We feel safe there-

...in 1857, at Ashby-de-la-Zouch, at West Harptpool, and elsewhere: Corn Exchanges, on some of which a large amount of money has been expended — at Colchester (by Raphael); at Norwich (by Mr. Irwin), perhaps the most finished example in the country; at Grantham, at Hitchin, at Louth (a handsome Venetian pile, by Mr. Bellamy); at Banbury, at Hemel Hempstead, at St. Albans, at Grimsby (Elizabethan, by Bellamy and Hardy); at Gloucester (a large and ambitious Corinthian edifice, by Medland and Mabery); at Hereford (Italian, by Mr. Holmes), &c. — Assist Courts at Reading (by Mr. Clary); at Taunton, at Swanscombe, &c.; County Courts, Post-Offices, Music Halls (some of the very recent ones, like that at Birmingham, the New Market, London), and at least in the protective works; Lyceums, Mechanics Institutes, Free Libraries, Baths, &c.

...beyond the limits of the towns among the largest and most costly, and from their size and character often the most remarkable modern buildings, are the Manufacturers' Asylums, but it must suffice to refer to them thus generally. The County and Borough jails are often curiously enough works of an inordinately ambitious architectural character; such as Rochdale (by Mr. Hardcastle); Swindon (by Mr. Stone); and there are now in England at Protestant and G Roman Catholic, must likewise be named in this connection.

...of industrial establishments of a more pleasing order — such as Marshall's Flax Mills, at Leeds; the extraordinary manufactories of the Westmoreland Mill at Bradford, and other great manufactories of recent erection — we should be glad to speak for, they, in their architectural character, and in their admirable arrangements, are among
the most striking evidences of material improvement in the country. But we must pass them by, as we must also pass by the many others, the work of which is connected with the railways, remarkable and notable as they are. In every way are among the recent public works of England. So again we must pass by the magnificent new docks, &c., as well as those constructed by public bodies in the town of London, the Thames at Blackwall, and elsewhere, as vast as they are in extent, and costly but most important in character; and the equally magnificent works which have been in progress in the south of England, which are to provide accommodation for our large mariners harbours from the perils which beset them. The defensive works which are erected on the more vulnerable parts of our coast, and for affording additional protection to our naval ports and arsenals, hardly public buildings in the best sense of the word. Even on Public Improvements, hence such an article ought scarcely to conclude without at least a reference to the great naval and military hospitals which have been recently erected or are in progress at Plymouth, Portsmouth, Spithead, Chatham, &c.; and although we have heard much of deficient barracks accommodation, even that must be largely increasing, and ought to be rapidly improving when we see by parliamentary returns that in a single year, 1856-7, upwards of a million sterling has been spent in building barracks and stables at various stations (amounts 868,008l., repairs 292,746l.). Of the many mansions which have been erected in the country we must also refrain from speaking, though the list is headed by her Majesty's Marine and Highland palaces at Cowes and Dalmoral.

112. The most important single undertaking of the present time was undoubtedly set forth the progress of public improvement in England during the last twenty years. In Scotland and Ireland architectural progress, taken as a whole, has not been proportionate to that of the sister country; yet when we look at the noble buildings which have been erected in Edinburgh and Glasgow, the unrivalled railway termini and some other recent buildings in Dublin, the warehouses and public works in Belfast, the Irish Queen's Colleges, &c., we cannot but feel that we have made a great stride in the path of architectural progress during the past twenty years.

PUBLIC LIBRARIES. [LIBRARIES, PUBLO, S. 2.]

PUFINUS. [Petrvs.]

PUGIN, AUGUSTUS, an eminent architectural draftsman, was a native of France, but settled in London at an early age. He was engaged as a draftsman and assistant by Nash, with whom he remained many years. He then found employment at the old firm of Inigo Jones, and at the same time was engaged in Architectural drawings for engraving; one of the most important of his earlier works being the engravings in Ackerman's 'Microcom of London,' 1808-11. He also made the drawings for a 'Series of Views in Islington and Fentonville, with descriptive text'; and in 1821 he published a work on his attention more particularly to the architecture of the middle ages; and in 1821 he began the publication of his 'Specimens of Gothic Architecture, selected from various Architectural buildings in England; consisting of Plans, Elevations, Sections, and parts at large; calculated to exemplify the various styles, and the practical construction of this class of admired Architecture;' it was completed in 1823, and forms 2 vols. folio and 4to, containing 144 plates, with descriptions, chiefly by Mr. E. J. Wilson. In 1824 he commenced, in conjunction with Mr. John Britton, 'Architectural Illustrations of the Buildings of London,' also completed in 2 vols. 4to; and with the same gentleman he published, in folio and quarto 1825-29, 'Specimens of the Architectural Antiquities of Norman and Gothic Architecture,' by A. Pugin, and engraved by John and Henry Le Keux. This is his best and most important work, and did much to enlarge our knowledge of mediæval architecture; he was assisted in this work by his son, the subject of the succeeding notice. In 1839 Mr. Pugin made the drawings for a work entitled 'Paris and its Environs displayed;' and in 1833 he prepared, with the assistance of his son, 'Gothic Ornaments, selected from various buildings in England and France.' He died December 8th, 1860.

PUGIN, AUGUSTIN WELBY NORTHMORE, son of the preceding, was born in 1811. Instructed by his father in the principles of architecture, he early acquired under him considerable practical knowledge of the business, and was employed as assistant, collecting materials in Normandy and England for his works on Gothic architecture. [Pugin, A.] His first distinct employment was as assistant to Messrs. Gribbe, in painting the architectural scenery in her Majesty's and Covent Garden theatres. He was furnished with a variation of drawings for the furniture in Windsor Castle, and designs for in the usual style for Messrs. Rundell and Bridge. In 1833 he removed to Ramsgate, and commenced preparing for publication a series of works illustrating the furniture and ornamental work of the period, as shown in the ancient edifices of England. 'The Gothic Furniture, in the style of the Fifteenth Century,' and 'Designs for Iron and Brass Work, in the style of the XVth and XVIth centuries.' These were followed in 1836 by 'Designs for Gold and Silversmiths' Work,' and 'Ancient Timber Houses, all of which were received with marked favour, and tended not a little to stimulate the growing taste for Gothic forms. His next work was one that, by its curious and irritating way of setting forth some home-truths, aroused not a little professional animosity. In the late periodical, 'The Builder,' he published the Noble Edifices of the 14th and 15th centuries, and similar buildings of the present decay of Taste,' a second and improved edition of it was published in 1841.

Mr. Pugin had by this time joined the Roman Catholic Church, to the service of which he henceforth devoted his best energies. Having received a handsome bequest from an aunt, Mrs. Welby, he built himself a fanciful residence in the neighbourhood of Salisbury, and removed there, resolved to give himself unreservedly to the work of a designer and architect of a Roman Catholic Church, and to attempt the reconstruction of the middle ages. Having found in the Earl of Shrewsbury a warm patron, Mr. Pugin soon obtained opportunities of exerting his ability; and during the few years that he lived to practise his profession he was called upon to execute a large number of buildings for monasteries, convents, and schools, than has probably fallen to the lot of any Englishman since the Reformation. The following list, we believe, includes his chief works—(we are indebted for it, and many of the other facts contained in this notice, to a memoir of Pugin by his friend Mr. Talbot Bury, who appeared in the 'Builder shortly after Pugin's death')—: The cathedral church at St. Marie at Derby, one of his earlier and more pleasing works; St. Chad's, Birmingham; three churches in Northampton; St. Wilfred's at Wilton near Alton; a church, and a convent and chapel, at Nottingham; convents of the Sisters of Mercy at London, Birmingham, and Liverpool; a priory at Downside near Bath; the vicarage of Hawkhurst, Kent; a convent and convent at Edge Hill; churches at Oxford, Cambridge, Reading, Keighworth, Stockton-on-Tees, Newcastle-upon-Tyne, Preston, Kloof, Rugby, Northampton, Stoke-upon-Trent, Bolton, Wrexham, Lichfield, Hexham, Deventer, and Swanage; a new Manufacturing Institution, and a convent and church at St. George's (Southwark), Killarney, and Emmiscotry. To these must be added the extensive and costly works executed for his great patron the Earl of Shrewsbury, consisting, besides his palace at Shrewsbury, of houses, schools, and a convent, and monastery at Alton Towers; and a church at Cheddle, which has the most splendid interior of any of his churches. The very pretty gateway to Magdalen College, Oxford, is one of the few works executed by him for any Protestant body; indeed he is said to have refused to accept any commissions for Protestant places of worship. The list of works given above would in truth seem to have been more than sufficient to exhaust the time and energies of a man who ceased working at the age of forty; yet he was chiefly employed during his last years in designing and superintending the ornamentation of the New Palace of Westminster, which probably owes its somewhat extravagantly mediæval and ecclesiastical character to Pugin's idiosyncrasy and impatience of modern style. But in the practice of his profession, he found time to add to its literature a second and revised edition of his 'Centrals'; a treatise on the 'True Principles of Pointed or Christian Architecture,' 1841; 'An Apology for the Reformation of Christian Architecture,' 1843; a 'Glory of Ecclesiastical Ornament,' 1844; a treatise on 'Floriated Ornaments,' 1849; and 'A Treatise on Chancel Screens,' 1851. We ought also to add that he was connected commercially with the house of Mears. Hardman of Birmingham, who manufactured mediæval and ecclesiastical houses of wood; and it is said that he had filled np his leisure hours with landscape-painting.

Mr. Pugin had always been fond of the sea—(indeed it is stated in one of the biographical notices of him that he once said to an old master at sea, 'You poor seaman! Why, you're living in Holland,' though it is difficult to see when that time could have been)—and having realised by his profession a
handsome sum, he purchased an estate at Ramsgate, in order
at once to enjoy his favourite element, and carry out un-
feathered his notions of architectural propriety. Here he expended
all his property in erecting for himself a house, a church,
schools, etc., the whole being dedicated to St. Augustine. As he
lived in peace in his religious feelings took more and more
entire possession of him. He now (1850) wrote and pub-
lished 'An Address to the Inhabitants of Ramsgate,' An
Earnest Appeal for the Revival of the Ancient Plain Song,
'The Present State of Public Worship among the Home
Catholics,' and 'On the Ecclesiastical Architecture of a Great
City.' At length, overthrown by all these excessive labours and ex-
termination, his intellect began to give way, and in his fortieth
year it was deemed necessary to remove him to a lunatic asylum.
For a brief space his mental powers were so far restored that
it became practicable for him to return to his home at Ram-
sgate; but his life was ebbing, and he expired there on the
14th of September 1852, three days after his return. He
was buried in a vault of his own church of St. Augustine.
He had been three times married, and shortly after his death
a pension of 100l. a year was granted to his widow from the
Civil List.

As will have been seen, Mr. Pugin was a man of extraor-
dinary industry and energy, and he possessed a phlegmatic
and philosophical mind, and a great ability. He attempted too
many things, and he worked too much and too fast to pro-
duce many great works, even had he been a man of original
power; but in truth his was not a creative mind, and he
lacked comprehensive thought. His great principle was, that,
except as to size, the architect should aim at a faithful
reproduction of an ecclesiastical edifice of the medieval
period; or, as he said it in his 'True Principles of Pointed
Or Gothic Architecture,' 'We may indeed improve in me-
chanical art; a master to guide its construction—we may even
increase its scale or grandeur; but we cannot successfully
devote one tittle from the spirit and principles of Gothic
architecture. We must rest content to follow, not to lead.
We may indeed widen the road which our Catholic fathers
formed, but we cannot depart from their track without a
certainty of failure being the result of our presumption.'

Following such a dogma, it is evident that the highest success
must be a respectable imitation. But even on his own prin-
ciples was woven to his works are entirely satisfactory as a whole;
in particular parts and in details he is generally very happy,
and some of his interiors have a rich and pleasing effect. His
writings have had a powerful influence on the taste and prac-
tice of professed architects, and still more on the taste of
ecclesiastical amateurs, and the influence has not been entirely
a happy one. More than any single man perhaps has he been the
cause of that perverse fashion which has predominated
during the last fifteen or twenty years, of building modern
churches in all their parts on the precise model of the churches
of the middle ages, although—at least in Protestant churches
—the forms of worship and the requirements of the congre-
gations are so changed. In Pugin it was consistent: in his
Protestant disciples it is absurd.

PUJAH, OR PUNJAH. [HINDUSTAN.]

PULI, OR THE ELEPHANT. [HINDUSTAN, S. 1.]

PUSEY, PHILIP, elder brother of the Rev. Edward
Bouverie Pusey, D.D., was born in 1799. Having succeeded
in 1829 to the Pusey estates in Berkshire (held originally by
the tenure of a horn, which has been in possession of the
family upwards of 800 years), he became member for the
borough of Chippenham in 1830, and in the following year
for that of Cashel. In December, 1834, he was elected for
Berkshire, for which he had been an unsuccessful candidate
two years previously; and he continued to represent that
county until the election of 1826. A Conservative in
politics, and a decided supporter of the Corn Laws, on finding
that agricultural protection, however desirable he might
deem it, was practically unattainable after the passing of the
Corn Law measures by Sir Robert Peel in 1846, he, instead
of continuing with the bulk of the Protectionist party to
agitate for a repeal of the free trade measures, urged the
agriculturists to make the best of their position, and to adopt
without delay every improvement which scientific investiga-
tion and practical experiment had shown to be beneficial, in
order to enable them to compete advantageously with the
foreign producer. Already well known as a practical agri-
culturist, and as one who had given his attention to, and
carefully watched and tested, every scientific improvement
which had of late years been suggested to him (the system of
drainage, ploughing, and reaping, his advice was listened
to with respect, and his various practical papers in the
'Agricultural Journal' were received as authoritative, and
probably the influence of his high character and sober
judgment may be attributed in no small measure the great
advance which has been made within the last few years in
every department of English agriculture. Mr. Pusey was
president of the Royal Agricultural Society of England in
1854, and one of the chief contributors to the Journal of that
society, which he also edited for several years. He died
July 6, 1855.

Quatemère de Quincy occupied a prominent and influential place among the French writers on the history and theory of art. He outlined however his reputation as an archaeologist, for his learning was but shallow as compared with later scholars, especially those of Germany; and as a writer on the principles of art, he was a superficial writer than profound. Yet his work contains much valuable material, and his speculations are mostly interesting, however unsatisfactory. The following, in addition to those already named, are his principal works: - *Lettres Addressées à M. Canova sur les Marbres d'Egée*, *Svo. Roche-Quincieux, 1805,* *Histoire de la Nature, du Bât, et du Moyens de l'Umination dans les Beaux Arts,* *Svo.* 1833 - the most original and the most satisfactory of his speculative works; *Lives of Rafflesie* (1834), of the Most Celebrated Architects (1830), of Canova (1834), and of Michel Angelo (1850) *Svo.* and *Ouvrages des Antiques restitués d'après les Descriptions des Etrangers Grecs et Latins,* 2 *Svos.* 4to, 1829-37. Two of his works have been translated into English, *The Destruction of the Works of Art,* and the *Writings which they have applied with regard to their Influence on the Genius and Taste of Artists, and the Sentiments of Amateurs,* by Henry Thomson, 12mo, 1821; and the *Essay on Imagination in the Fine Arts,* by J. C. Kent, *Svo.* 1827.

QUEENSTOWN, or COVE OF CORK, County Cork, Ireland, a sea-port town, is situated on the south side of Great Island, in 51° 51' N. lat. 8° 18' W. long. distant by road 14 miles E.S.E. from Cork, and 167 miles from Dublin. The harbour was established in 1861, about 11,428. Previous to the French war Cove was a small village consisting of fishermen's cabins; it then rose into importance by becoming an admirals station. It was the port of embarkation for troops going on foreign service, and a place of rendezvous for merchant vessels about to sail under convoy. It now depends on the number of invalids who resort to it, especially in summer, when it is much frequented as a favourite bathing-place. The name was changed from Cove to Queenstown on the occasion of her Majesty's visit to Cork in 1850. The town, which occupies a steep acclivity over looking the harbour, consists of several streets rising one above another in lines parallel to the beach. It contains a handsome parish church, erected in 1812; a Roman Catholic chapel, which serves the priest of the diocese of Clonard and Ross; a Wesleyan Methodist chapel; national schools; a club-room; a literary society; a public library and reading-rooms. It has also a market-house, a fever hospital, dispensary, and laundry. That part, erected in 1868, forms a fine promenade, commanding a view of the magnificent harbour. The harbour of Cove is 3 miles long by 2 miles broad, with an entrance 2 miles long and 1 mile wide. It contains Spike Island, on which are artillery barracks and a depot for convicts; the small island of havellin, with the ordnance depot, and near it Rocky Island, with two powder-magazines cut out of the rock. Steamers ply daily in summer between Queenstown and Cork. The Royal Yacht Club of Cork holds its annual regatta in the harbour. Petty smuggling is still carried on. A market is held on Saturday, QUERCUS. *[Chemistry, S. 1.]* QUERCUS. *[Chemistry, S. 1.]* QUINCEY, DE. *[Quinçemer de Quincey, S. 2.*] QUINODINA. *[Chemistry, S. 1.]* QUINolin. *[Chemistry, S. 1.]* QUINOLEIN. *[Chemistry, S. 1.]* QUINQUINA, or QUINA, names given to the species of plants which are generally referred to the genus Cinchona, in the article *Cinchona.* The word *Cinchona* was first found in an account of the species of *Cinchona,* as recognised by botanists previous to the investigations of M. Weddell. This traveller dwelt in the Cinchona districts of the Andes during the 1830s and gave the above account of this subject, entitled *Histoire Naturelle des Quinquines.* In addition to a highly interesting account of the districts, M. Weddell gives a full description of the methods of preparing the Cinchona Bark by the natives, who live in the forests. By dwelling on the spot he was enabled to correct many that were erroneous with regard to the nature and character of the species used in medicine. He also discovered the real plant which yields the yellow-bark, that furnishes the greatest quantity of quinine. The following table from M. Weddell's work exhibits the names of Commercial Cinchona Barks, and the species from which they are believed to be obtained:

I. -GRAY CINCHONA BARKS.

§ 1. Loza Cinchona Barks. (Crown Bark, Angl.-China, Loxa, Kron China, Germ.)

Loxa Cinchona Bark, grey compact; *[Chemistry, Pav.*] C. ericoides, H. et B.

Loxa Cinchona Bark, brown compact; *[Chemistry, Pav.*] C. ericoides, H. et B.

Loxa Cinchona Bark, red chestnut; *[Chemistry, Pav.*] C. ericoides, H. et B.

Loxa Cinchona Bark, red fibrous of the King of Spain. (Quina Espoas, Pav. in collect., Lamb. Mus. Brit.)*

Loxa Cinchona Bark, yellow fibrous; *[Chemistry, Pav.*] C. macrolepis, Pav.

§ 2. Lima or Huanuco Cinchona Barks. (Silver Bark, Gray Bark, Angl.-China-Huanauc, Graue China, Germ.)

Lima Cinchona Bark, grey-brown; *[Chemistry, Pav.*] C. micrantha, Ruiz et Pav. or *

Lima Cinchona Bark, grey ordinary; *[Chemistry, Pav.*] C. micrantha, Ruiz et Pav.

Lima Cinchona Bark, white; *[Chemistry, Pav.*] C. micrantha, Ruiz et Pav.

Lima Cinchona Bark, very rugged, resembling the Calisaya Bark; *[Chemistry, Pav.*] C. micrantha, Ruiz et Pav.

Lima Cinchona Bark, red, of Juan or of Loxa; *[Chemistry, Pav.*]

II. -RED CINCHONA BARKS.

Red Cinchona Bark, becoming white in the air; *[Chemistry, Pav.*]

Red Cinchona Bark of Lima; *[Chemistry, Pav.*]

Red Cinchona Bark true, non-verrucous; *[Chemistry, Pav.*] C. micrantha, Ruiz et Pav.

Red Cinchona Bark, officinal; *[Chemistry, Pav.*]

Red Cinchona Bark true, verrucous; *[Chemistry, Pav.*]

Orange-Red Cinchona Bark, verrucous; *[Chemistry, Pav.*]

Pale-red Cinchona Bark, with a white surface; *[Chemistry, Pav.*]

Brown Carthagena Bark; *[Chemistry, Pav.*]

Red Carthagena Bark; *[Chemistry, Pav.*]

III. -YELLOW CINCHONA BARKS.

Yellow Cinchona Bark of the King of Spain (Carcassonne Armariel del Rey, Labuert).

Caliaya Cinchona Bark, or Royal Yellow Bark (Kings China, Germ.-Yellow Bark, Angl.-China Regia, Bergen)

Orange-Yellow Cinchona Bark; *[Chemistry, Pav.*]

Cinnamomum Bark, or Quinaequina, (Quina-canella), Light Caliaya; *[Chemistry, Pav.*]

Caracassena Clara-Amarilla, (Labuert). Pitya Cinchona Bark (Quinaquina de la Colombia, or Antioquia, Quina, Quinaquina, Caracassena Parida a la Caliaya, Labuert). *[Chemistry, Pav.*]

Caracassena Clara-Amarilla, (Labuert).

C. cinnamomum, Ruiz et Pav.

C. cinnamomum, Ruiz et Pav.

Coromomum, Ruiz et Pav.

Coromomum, Ruiz et Pav.

Coromomum, Ruiz et Pav.

Brown Carthagena Bark; *[Chemistry, Pav.*]

Red Carthagena Bark; *[Chemistry, Pav.*]

Yellow Carthagena Bark; *[Chemistry, Pav.*]

C. cinnamomum, (Labuert).

Brown Carthagena Bark; *[Chemistry, Pav.*]

Red Carthagena Bark; *[Chemistry, Pav.*]

Yellow Carthagena Bark; *[Chemistry, Pav.*]
We be, the or, from certain the be entirely smooth, cellular peculiar and but texture. The following remarks:—

2. Huamaliea Yellow Loosely short
3. White Cinchona Bark
4. White Cinchona Bark, ferrugi-
5. Cinchona Bark
6. Arica Cinchona Bark
7. Pale-Yellow Cartagena Cinchona Bark
8. Cinchona Bark
9. Alica Cinchona Bark
10. Yellow Orange Bark
11. Pitaya Cinchona Bark, or False Pitaya Cinchona Bark

The following, according to M. Guibourt, are the most active barks:

1. Calisaya Cinchona Bark
2. Yellow Orange Bark
3. Pitaya Bark
4. Yaucous True Red Bark
5. Von-Verrucosa True Red Cinchona Bark
6. Red Lima Bark
7. Gray Lima Bark
8. Verrucous White Huamaliea Bark

On the subject of distinguishing the various barks of commerce, M. Weddell points out the falsity of the present mode of distinguishing the sorts of bark by the color, red, yellow, and gray, as frequently the same barks at different ages have different colors. Having shown also the impossibility of a chemical classification, he proceeds to make the following remarks:—

"If a classification be absolutely needed, one which should be based on the anatomical structure of the bark would be found to be of far greater utility than either of the preceding, inasmuch as we shall find existing, even in the Cinchonas, a marked relation between the structural and chemical characters.

"The following are the data which my researches on the subject have furnished me with:—

1. If we take a small piece of the bark of C. esobrculata, we shall find that instead of these fibers of fibrous texture, which so well characterise the C. calisaya, the exterior almost presents a smooth surface of a cellular texture, similar to the inner surface of the bark or of the layer which is immediately in contact with the wood. The examination of a transverse section shows that the texture of the bark is homogeneous, and composed of lignous fibers of almost uniform thickness, uniformly dis- tributed in the midst of cellular tissue gorged with resinous matter, tissue which may be said to isolate each fiber, being interposed in thin layers between them. Finally, when these fibers are seen side by side and longitudinally, we find that they are short and fusiform, and that their cut extremities are not loosely attached to each other, and are sometimes completely separate, and appear to float in the midst of the cellular tissue which surrounds them.

2. If we take a similar piece of the bark of C. esobrculata, we shall find that instead of these fibers of fibrous texture, which so well characterise the C. calisaya, the exterior almost presents a smooth surface of a cellular texture, similar to the inner surface of the bark or of the layer which is immediately in contact with the wood. The examination of a transverse section shows that the fibers are more numerous than in the C. calisaya, especially towards the inner surface, and are found in numbers rapidly near the exterior, and the outermost layer is entirely without them. These fibers, if examined in a longitudinal section, will be found to be of nearly the same length of those of the C. calisaya, and their extremities are invariably attached to the other, their ends being by this means more elongated.

"If we study with equal attention the bark of C. pseudoboea, we shall there find a similar structure. The external surface somewhat resembles the preceding bark, with the exception of a slight whitish marking, formed by the continuity of the periderm, and scissions which may result from desication. The internal surface is fibrous, as in the preceding, but a transverse section shows that it is principally composed of cellular tissue, in which the fibers form but a small number of irregular and concentric series in the interior half of the bark; and that which is present in the greatest quantity is the size of these fibers, each one being three or four times as large as those of either of the former varieties; the result being that several of them are attached and united together in bundles, which may be fully proved by the examination of a longitudinal section of this bark.

"As may be perceived, we have only spoken of Cinchonas which have been deprived of their periderm, because it is in this state that they are now usually met with in commerce. If perchance they were used again to be used with their natural coating, it would afford additional means whereby to distinguish them, but would not in any way affect those of which we have just treated; for nothing would be easier than to remove the periderm and to expose the surface beneath. Be this as it may, the structure of all the Cinchonas barks more or less resemble one or other of the three types we have spoken of, and on this plan there might be formed, without much difficulty, a series of groups comprehending all the barks. The purpose however in noticing these peculiarities, has been to facilitate the comprehension of a very important fact in the diagnostical character of the different kinds of Cinchonas; that of the vast difference they present in their mode of fracture. However singular it may in the first instance appear to be, it is easy to prove that, to a certain extent, the chemical composition of the bark operated upon may be determined by its mode of fracture; or, more properly speaking, there exists a relation between the chem- ical and physical characters of the Cinchonas, this being constantly proved by a particular form of fracture: smooth or corky where it divides the tunic or cellular covering of the bark; fibrous, stringy, or woody in those cases where it has affected one or other of the three forms of liber before described. Another fact which is now fully proved is, that the bark containing the largest proportion of quinine is that of the C. calisaya; and experience has shown us, that after the C. calisaya, the barks possessing it in the greatest quantities are precisely those the structure of which most resembles this bark; for instance, those in which the periderm is reduced to a single liber by the successive exfoliation of the outer tunics, or at least by their adhesion to the fiber, the case of the Cinchonas C. peruviana and C. arica, in which we also have shown, to a certain extent, that the Gray Cinchonas (which we have generally found to be the young barks of other species) contain a larger proportion of cinchonine than of quinine; we also know that many old barks, which have retained the cellular coating they had when young, yield a proportionally larger quantity of cinchonine; from which circumstance we may conclude that quinine is contained in the liber, or, more correctly speaking, in the cellular tissue interposed between the fiber and the liber, and that the cinchonine is principally found in the tunic or cellular coating. As to the tannin, it is found in larger quantities in this latter part than in the fibers tunic—a fact which is easily determined with reference to the fresh bark where the external layers of the derm are more strata than the internal layers." ('Pharmaceutical Journal,' vol. ix.)

The following are the specific characters of the Cinchona calisaya:—Leaves oblong or lanceolate, obvolute, obtuse, toothed along the side; resemble those of the Cinchonas, but are more acuminate, rarely acuminate aristate, or polished, or pubescent beneath; scrobiculate in the axis of the veins; filaments usually shorter than one-half the length of the anthers; capsule ovate, scarcely equal in length to the flowers, frequently fringed, dentilicate at the margin. Of this there are two varieties.

1. C. C. vera. A tree with oblong-obovate or obvolute lanceolate leaves.
2. C. C. Joroppiana. A shrub with somewhat acute-oblong lanceolate or obvolute leaves.

Both varieties are natives of Bolivia and Southern Peru. ('Pharmaceutical Journal,' vol. ix.)
QUINTANA, MANUEL JOSÉ, a very eminent Spanish poet and patriot, remarkable for the depth of his feeling in both characters, and remarkable also for the strange vicissitudes of his long career, was descended from an Extremaduran family, the native of Madrid, where he was born on the 11th of April, 1772. He studied and took his degrees in canon and civil law at the University of Salamanca, where he became intimate with the poets Cienfuegos and Melendez, who introduced him to the friendship of Jovellanos (Jovellanos, the secretary of the Spanish ministry of the interior, and a representative of liberal ideas in Spain. Quintana was from the first distinguished for his spirit of manliness and independence, and when he commenced his career as an advocate at Madrid, his house, at which a party of literary people assembled, every visitor was received with the same politeness by all those who were opposed to the degrading policy of Godoy, the all-powerful favourite of the day; while the house of Moratin, the dramatic poet [Moratin], the other literary focus, was the resort of those who paid homage to the minister.

From about 1795 Quintana became known as a poet only second to his friend Melendez, and in almost every case the themes he selected were of a large and lofty character, and treated in a corresponding strain. One of the finest odes in the Spanish language is his 'To the Sea,' but at the same time to his twenty-sixth year without ever beholding the ocean, and in 1798 he was seized with so irresistible a longing to fill up the deficiency, that he made a journey from Madrid to Cadiz for that express purpose, wrote the ode, which is not now preserved. Still he would have been noticeable in any country, but it was particularly so in that country and age, for, as Alcalá Gallano remarks, in his excellent history of Spanish literature, traveling, except on business, was of no part in the habits of Spanish life. Many of Quintana's other odes are scarcely less admirable than this, and they constitute by far his best title to poetical fame. It may be remarked that the patriotism, which is the animating principle of almost every one of them, is not gross, but at the same time a narrow feeling. Two of these odes, which will be found translated into English in Kennedy's 'Modern Poets and Poets of Spain,' are on the introduction of vaccination into America by the Spaniards, and on the battle of Trafalgar. In the first he alludes to the creative discovery of Jenner, Quintana exclaims—

"The gift of the discovery is the gift Of chance; that let an Englishman enjoy, But let Spain show her noble, generous heart," etc.

by conveying it to her colonies, apparently forgetting that England imparted the discovery not only to her own colonies, but to all the rest of the world, with the exception of France, which had been the first nation to which it was given. In the ode on Trafalgar, the battle is represented throughout as between the English and Spaniards, the French not being even mentioned with a notice of the battle, and the poet appears to think, he says, of the sword, gun, and death of the brave memory of Nelson by saying, "As an Englishman, I abhor thee; but as a hero, I admire." These points are worthy of notice as characteristic not only of Quintana but of the majority of his countrymen. In dramatic poetry Quintana was far less successful than in lyric poetry. As early as in 1791 he had contended for a prize offered by the Spanish Academy for a poem on the 'Rules of the Drama' ('Las Reglas de la Drama'), and in this production he exhibited a decided bent for comedy, marked by unbounded admiration for Corneille and Molieres, makes but inkwarm mention of Lope, Calderon, and Moreto, and none whatever of Shakepspeare, though, probably in consequence of his friendship with Melendez, he had studied English. In his own tragedies, of which he gave two to the public, the same line of thought is apparent. One of them, "El Duque de Viseo" ('The Duke of Viseo'), acted in 1801, is acknowledged by the author to be founded on an English drama, which he had studied. The other is the 'Spectre de L'ace,' an episoden of the villain's dream, is evidently taken from the well-known dream of Oomk Lewin's 'Castle Spectre,' but in other respects the resemblance is very slight. The other tragedy, 'Felayo,' which is somewhat better, is not so very admirable, but has a few passages which are very remarkable, and reading like passages from the author's odes.

Up to the time of the French invasion in 1808, Quintana's position continued one of great prosperity. As an advocate in spite of his liberal opinions, he held several important offices, among others, those of fiscal agent of the junta of commerce, secretary of the department for the interpretation of foreign languages, and censors of the press. The great literature man his reputation was constantly increasing. He entered a periodical entitled 'Variedades,' which was considered the best of its time in Spain. In 1807 he issued the first volume of a prose work, "Vidas de Españoles célebres" ('Lives of Celebrated Spaniards'), which was much bought and read, and was going on to Gonzalo de Cordova, the Great Captain. In the following year he published in three volumes a selection of specimens of the best Castilian poetry from the time of Manrique de la Cerda to Moreto, to which he prefixed a short history of Castilian poetry, and a dissertation on the thing of the kind that had before appeared, and which was afterwards rendered into English by Wiffen as an introduction to his translation of 'Garciaco de la Vega.' This was in the year of the French invasion. That great event had a very different effect on the three friends, Cienfuegos, Melendez, and Quintana. Cienfuegos, seized by Murat, and sent a prisoner to the south of France, died of indignation at the treatment of his country and himself; Melendez passed over to the ranks of the insurgent Castilians, to which all the literary antagonists of the French by far the most active and the most dangerous. He was the author of most of the manifestos of the insurrectionary Junta, the fervid eloquence of which strengthened the party of the insurgents. Of documents of the first Cortes. His weekly periodical, 'El Semanario Patriotico,' was the leading organ of the patriotic party, and exercised great influence on the march of events, for Quintana was no less uncompromising an advocate of the national independence than the French invader. The six years of the war were the most glorious of his long life. They were followed by six years of imprisonment. The return of Ferdinand VII. was to Quintana, as to all Spaniards of the shades of the signal of ruin. His having been the advocate of the Cortes and of constitutional government was regarded as a crime that called for punishment. He was suddenly seized and thrown into the fortress of Pamplona, where he was left imprisoned with no hope or promise of release, debarred from all intercourse with his friends, and not allowed access to pen and ink. In this state of rigorous incarceration he remained till he was released by the outbreak of Riego's insurrection, on the 1st of January, 1820. He was then at once set at liberty, saw himself surrounded with popularity, restored to his old offices and honours, and was named president of the department of public instruction, but he was no longer the man he had been before his imprisonment. His depreciation of tyranny was still strong, and he endeavoured to bring about the continuance of the new order of things, and with guarded prudence he abstained from making himself conspicuous in the ranks of the liberal party. When the second French invasion overthrew the constitution, he received the reward of his resigned allegiance to the country, Spain, while his friends and companions took refuge in England and France. Commanded to leave the capital he retired to Cabeza del Buex, the town in Extremadura to which his ancestors belonged, and there lived in obscurity and absolute poverty for some years. In this retreat he composed a series of 'Letters to Lord Holland,' with whom he had become acquainted at Madrid, which contain an eloquent and touching vindication of the proceedings of the Cortes, which, as he THEREFORE, had been prohibited, and a vindication of the injuries with which they had been treated by England. These letters, the last of which bears date in 1824, were of course carefully concealed at the time they were written, and did not see the light till they appeared in a collected edition of Quintana's works in 1826. On the Victoria of Ferdinand's marriage to his third wife, Queen Maria Christina, in 1826, he sent an intimation to Quintana that he would be permitted to return to Madrid, if he would write an ode in praise of his new queen. The poet naturally hitherto been that he had never written a line in praise of the powers that were, and his friends were at once grieved and astonished to find that he complied. The poem was pronounced to be the best of all that were produced on the event, although it was not the first, and the worst Quintana had ever written. The poet returned to Madrid, was no longer regarded as inflexible, and found himself on the road to fortune. Soon after he was named a member of the committee of the Museum of Natural History.
RADETZKY DE RADETZ, FIELD - MARSHAL, COUNT JOSEPH, was born at the castle of Trahincze, in the Klatitzer district, in Bohemia, on the 2nd of No-

vember, 1763. He was the son of Count Polar Besehicz Radecky, and of the Baroness Maria Bebychyna. The family name was formerly spelt Hradecky. Having entered the army as cornet, in the 2nd Austrian Cuirassiers, in 1784, he became sub-lieutenant, February 3, 1787. In 1788 he served in the Turkish campaign under Marshal Lacy, and was raised to the rank of first lieutenant for his services at the siege of Belgrade. When the Austrian army entered France in 1793, Radecky, then a captain, was sent to the new scene of war; and he was present in all the Italian campaigns from 1795 to 1800, serving alternately under Beaulieu, Warmer, Alvinia, and Ghega. In the battle of Arcola, Rivoli, and Marengo. Meanwhile, in 1797, he was promoted to the rank of major, and in 1799 he became adjutant-general to Melas, who soon learned to appreciate his zeal and gallantry, and repeatedly mentioned his name in his despatches. For his gallant behaviour at the battles of Novi (May 15, 1799) and Marengo (June 14, 1800), he was created colonel, and appointed to command the Archduke Albert's cuirassiers, and received the order of Maria Theresa.

From the peace of Lunville, in 1801, to 1805, Colonel Radecky was not employed in the field; but at the latter period he was made major-general. During the contest at Aspern, May 21-22, 1809, when the place was six times retaken by the Austrians from the French, few officers contributed so much to the victory as Radecky. On the 1st of June he received the command of the 4th corps, with the rank of lieutenant-field-marshall. At the battle of Wagram, July 6, 1809, he commanded the Austrian cavalry. In the battle of Stockhorn, in August, he was killed to the order of Maria Theresa. From that period until the end of 1812 his services were employed at home in the war-office.

During the whole campaign of 1813, while the tide of war had turned against Napoleon I., Lieutenant-Field-Marshall Radecky acted as chief of the staff to Prince Schwarzenberg; and the Austrian commander attributed the victory of Kulm mainly to Radecky's skill and gallantry. But his services were not so conspicuous after the battle of Leipzig, October 18, 1813, the plan of which he drew up. As well known this decisive action was a succession of battles which lasted three days. The Emperor of Russia and the King of Prussia were present, and 1800 pieces of artillery thundered over the field. Although he had been nearly thirty years in the service, Radecky received his first wound at Leipzig. Throughout the campaign of 1814 within the French territory he was continually in action, and on the 6th of March
he entered Paris, riding by the side of the Emperor Alexander. Radetzky was appointed in 1828 Commander-General of the Italian troops of occupation in Lombardy, and in the following year, when he was forty-six years of service, he was created field-marshal.

But it was the Italian insurrection, in 1848, which first gave prominence to the name of Radetzky. As early as the year before, the Austrian government had prepared the way for the Piave affair, by desiring the Piedmontese to promote the emolulding irritation. Societies were formed to diffuse the secret spirit of revolt throughout the entire peninsula. In 1847, the movement was all but brought to a crisis, when Anziani claimed and enforced the right to place a Jacobin as mayor of Milan. The insurrection, however, to which Guard was constituted in every Italian state. Then came the revolution in Paris, in February 1848, followed by similar movements in Vienna and Berlin, which raised the spirit of insurrection to its height.

On the 18th of March 1848, barricades were erected in every street in Milan; the fighting lasted for three days; after which Marshal Radetzky drew his troops out of that city, and retreated to Verona. The Austrian army at that time amounted to about 200,000 men, and was scattered over an extensive line of operations. Consequently the insurrecte were at first triumphant; the tricolor flag appeared upon all the towers of Italy, except those of Verona, Mantua, Legnago, and Peschiera; and Charles Albert, King of Sardinia, despatched a number of general officers to the gallant contest which was maintained for five months. More than once the Austrian colours had to quit the field; but every time they retired in good order. At other times victory was on their side. At length, on August 4, 1848, Radetzky, after a series of successful attacks on the Italian posts, advanced against Milan, at the head of the Austrian army; the Milanese lost heart, and deposed the monarchical officers; and Charles Albert, urging them to defend the city, they held a council of war. An attempt was made to send to Marshal Radetzky, and the terms obtained were:

"that the Piedmontese army was to be withdrawn in two days from the Lombard territory; that the Austrians were to enter Milan on the 6th of August; and that the lives and property of the people were to be respected." The struggle was now virtually at an end. Radetzky's superior strategy, and the diation of his opponents, rendered it an easy task for him to break up the Sardinian forces, and he was again master of Milan. A deposition was sent to Marshal Radetzky, and the terms obtained were:

"that the Piedmontese army was to be withdrawn in two days from the Lombard territory; that the Austrians were to enter Milan on the 6th of August; and that the lives and property of the people were to be respected." The struggle was now virtually at an end. Radetzky's superior strategy, and the diation of his opponents, rendered it an easy task for him to break up the Sardinian forces, and he was again master of Milan. An attempt was made to send a letter to the Emperor, after a prolonged service of seventy-three years in the Austrian armies. He died Jan. 6, 1859, at Milan.

Marshal Radetzky married in 1798 the Countess Frances Strassoldo-Gräfenberg, by whom he has left a son and daughter.

RAFFLESIAE, a natural order of stemless leafless Parasitical Plants, consisting of flowers growing immediately from the surface of branches, and immersed among scales. The perianth is superior, with a 6-parted limb, thickened processes or calli either distinct or united into a ring being attached to the throat of the tube. The essential organs are combined in a column which adheres to the tube of the perianth. Anthers 3-celled, either distinct and opening by vertical slits, or combined together so as to become a multinucellar mass opening by a common pore. Ovary 1-celled; placenta parietal. Fruit indehiscent. The species are East Indian and South American plants, parasitic on the roots of trees. The flowers are large and brilliantly colored. Some of them are said to be stinky. Their perianth has a fungoid appearance.

Rafflesia Arnoldi, a Semutra parasite, is capable of containing 20 gallons of liquid. The flower is said to some have to weigh a weight of 14 lbs.

R. Patens is employed as a stinking and stytic in Java.
of the Duke of Wellington, by whom he left two daughters and an only son, Richard Henry Fitzroy, now second Lord Raglan, who was formerly in the civil service at Ceylon, and afterwards held the post of secretary to the King of Hanover. His eldest son, Lord Raglan, was killed in the first Punjab campaign, while serving on the staff of Lord Gough, in December 1845.

RAIANIA, a genus of Plants so called in honour of the great naturalist John Ray, is known by the staminiferous flowers, having bell-shaped perianth in six deep oblong pointed segments, most spreading in their upper part. Corolla none; stamens with six filaments, bitrate-shaped, shorter than the calyx; anthers simple. Pistillate flowers, the perianth, consisting in six deep segments, permanent, withering; corolla none; pistil with the stamens inferior, compressed, with a prominent border at one side, 3-angled; styles 3, the length of the calyx; stigma obtuse; capsule membranous, smooth, crowned by the calyx; two of the cells barren, almost obliterated, without wings; the third fertile, compressed, extended into a very large half-ovate membranous wing; seed solitary, nearly elliptical, compressed.

R. hastata, Halberd-Leaved Raiania, is found in the island of St. Domingo. The root is perennial, sometimes large and ovate, sometimes 4, or 5 inches long, and 3 inches thick, round at each end. Its substance resembles that of a radish without any internal fibres, and light brownish- or reddish-coloured. A little above the root, the flesh very white, tasting like a bean. The flowers small, white, in simple axillary drooping clusters.

R. cordata, Heart-Leaved Raiania, has ovate leaves somewhat heart-shaped at the base, 7-ribbed. It is a native of the West Indies, from whence it was sent to Kew Gardens in 1786, by Mr. Alexander Anderson. Plummer represents the habit of the root, stem, &c., much like the foregoing; but the leaves are regularly ovate, pointed, more or less heart-shaped at the base, and furnished with seven ribs continued from that part to the point. These ribs are connected by numerous transverse veins.

R. ovata, Ovate-Leaved Raiania; has ovate-pointed 3-ribbed leaves, smooth, lanceolate, 7-ribbed; the stem, slender, smooth, hairy, and hard shrubby stem, turning thread-shaped, sub-divided with slender smooth leafy branches. The leaves rather distant, stalked, smooth on both sides, pointed, entire, 3-ribbed, being ovate at the base. The flowers dioecious, the males in compound clusters, females in simple ones; all stalked and turned toward one side. Corolla very minute, yellowish-green in the male, reddish in the female blossom.

R. angustifolia, Narrow-Leaved Raiania, is a native of the west side of St. Domingo, where it climbs upon high trees, flowering in May.

R. quinata, Five-Leaved Umbellate Raiania, has five leaves on a common stalk. It was observed by Thunberg about Nagasaki, and in Japan, flowering in April and May. The leaves are large, handkerchief-shaped, evidently membrane, divided into slender leafy branches. Leaves several together, axillary, stalked, smooth. Flowers in umbels from the same buds as the leaves, on slender stalks, as long as the footstalks.

R. cephalophora, Six-Leaved Clustered Raiania. Leaves six, on a common stalk, oblong-acute. Flowers racemose. It is a native of the country of Fakonia, in Japan, among bushes, flowering in April. The stem is round, striated, smooth, climbing. The flowers in axillary racemes, clusters approximated. The calyx is crowned in having mostly six leaveslets on a stalk, which are acute, reticulated, with veins at the back, and larger than in that species. The flowers moreover grow in clusters, not in umbels.

R. MYLIOBADUS, or RAINEA, a sub-genus of the family of Plagiotomus, distinguished scarcely, of which the Common Ray is the type. The body of these fishes is horizontally flattened, and more or less discous; the dorsal fins are mostly placed on the tail; a peculiar cartilage, called naso-pectoral, arises from the body, extends towards, or meets the anterior part of the crest or pectoral fin; the branchial openings are inferior. This sub-order is divided into the following families or tribes.

1. Cephalophoredæ, Horned Rays. They have a muzzle distinguished by two horn-like processes; the mouth before or beneath very broad; teeth very small, in some wanting in upper jaw; tail as long or longer than body, with a back-fin and apical tooth. The genus Cephalophorus has large lateral eyes and a transverse mouth, with small teeth like a file.

C. Hornæ is the only species known in the European seas. A specimen of this fish was once taken on the southern coast of Ireland. It has been described by Mr. Risso as a species inhabiting the Great of Nice. It approaches the shore, and is most frequently taken in the month of July. In Italy the small ones are called Vachetta, and the larger ones Vaciola. It dies immediately on being taken out of the water. It is a bad fish, and in some classes of the fishing is not caught. They grow to a prodigious size. Risso records a male weighing 800 lbs. and a female weighing 1900 lbs.

2. Myllobatidæ, Eagle Rays. The head is partially dis- engaged from the pectoral; mouth transverse; teeth large and quadrangular; the trunk was 6 ft. long, with a back-fin on root and a serrated spine behind. The genus Myllobatis has flat teeth; the central plate much longer than those which are lateral; pectoral fins wing-like; the tail armed with a large spine, set behind, with a small spine, near the root. M. apus, the Whip Ray, the Eagle Ray, and the Mul- len. This fish, though rare, has been found on the British coasts. Dr. Johnston has described a specimen found at Berwick-upon-Tweed. It inhabits the Mediterranean, and has been taken as far south as Cape Horn.

3. Trygonidæ, the Sting Rays. The head is laterally is closed by the pectorals; the teeth transversely elliptical; the tail without any fin, or merely a low vertical conical hair, and wide and not more than the serrated spine.

The single Trygon has the characters of the family.

T. pastinaca, the Common Trygon, the Sting-Ray, the Fire Flaire, La Pastinique of the French, is an example of this family. It was well-known to the ancients, who entered- tained some notion with regard to the venom of the spine of these fish. It is not unfrequent on the British coasts. The powerful serrated spine on its tail is used as an organ of defence.

R. ovata, the Skates. The body is rhomboidal; tail depressed, slender, generally with a low terminal fin, and frequently with rows of small spines; skin smooth or with small curved prickles; teeth flat, pavement-like, and pointed at the base. The skate is very frequent in the North Sea, and has two small fins near the end of the tail; the eyes and temporal orifices are on the upper surface of the head; the nostril, mouth, and branchial apertures beneath.

The Skate is a very common fish from the British coasts, and some of the species are used as food. The young are dis- posed in a similar manner to the sharks, in their horno cases of a square form, with four projecting horns, giving them the form of a butcher's try. These cases are very fre- quently picked up by the seamen. In Cumberland they are called Skato- Barrows, on account of their form. As the young fish increases in size it at last separates the edges of the horny layers in which it is inclosed, and escapes into the ocean. The Skate are the British species of this genus; and the longer of these fish in the southern parts of the British islam is called the Fresh Water Skate. For the Southern skate is called the Fresh Water Skate.

R. macrura, the Long-Nosed Skate, remarkable for its long pointed nose.

R. oxyrhynchus, the Sharp-Nosed Ray, the White Skate, the Burton Skate.

R. intermedia, the Flapper-Skate. This species was first taken in the Frith of Forth by Dr. Parnell, and first described by him.

R. batra, the Skate, the Blue Skate, the Gray Skate, the Tinker, La Raie Gondre of the French. This is one of the commonest species in our coast. The preceding species as well as this, the Thornback, and the Homely, are all com- monly called Skate.

R. marginata, the Border Ray. It has been only occa- sionally taken in Great Britain.

R. microelata, the Small-Eyed, or Painted Ray. This is a rare species.

R. mirularia, the Homely, the Home, the Sand Ray, and Spotted Ray. It is one of the commonest species along the coast. With the Thornback it is the most common species found in the London market.

R. spinosa, the Sandy Ray, Raye Râpe of the French. It has been only occasionally taken in the British Islands.

R. yagaren, a species of the genera of Rays is known by its rough back. It is only occasionally taken in the British Islands.

R. clavata, the Thornback, the Rough Ray. This Ray is easily distinguished by the spineless rays with which it is covered. Its flesh is regarded as the finest of all the Rays. It is in the best condition for the table about November.
and the capacity of secretaries, engineers, store-keepers, station-masters, trainmen, engine-drivers, guards, porters, post-office clerks, railway inspectors, and others.

Railways in England are now as extensive, or nearly so, as turnpike roads; but foreign railways have assumed a position of so much importance as to claim the attention of the most废旧的 men. It is a question whether the United Kingdom of having eight or nine thousand miles of railway open, it is of yet more importance to society at large that the other countries of the civilized world should be similarly provided; that prejudices of race and of creed should be softened down by intercommunication; and that each country should benefit from the produce of the others by interchange. It is no inconceivable a fact in the world's history that the Magyars of Hungary, the Slavonian of the eastern Russian, and the Italian of the new kingdom of Italy, should now be travelling in the same way, with locomotives displaying the same kind of highly-financed mechanism, as the inhabitants of the more developed and commercial countries of Europe.

We have yet to see whether European railways will ever be at peace, though the idea was entertained for so long as this is not the case, a railway line must inevitably be a line of civilisation. It is a "great fact" that a man may now "book through" from London to so many continents, in spite of new monastic customs, customs, and national jealousies. And if, direct communication across the Atlantic, we watch the progress of American railways, we shall there be struck with the conquests over the barren wilderness made in a few short years.

In Europe, the British railway system is so far advanced, that the lead. King Leopold proposed to the Legislature, in 1833, the adoption of a government system of railways; and a law was passed in 1834 in conformity with the proposal. The plan comprised a trunk line from Ostend to Liège, with lateral branches to Antwerp and Brussels; and a line from Brussels to the French frontier at Quiervain, making a total of about 247 English miles; in 1837 further lines were sanctioned from Ghent to Cointy, Cointry to Tournay, Braine-le-Comte to Namur, and Landen to St. Trond—a further distance of 94 miles; these various lines were opened to Brussels in 1835, to Antwerp in 36, to Ghent in 37, to Ostend in 38, to Cointy in 39, to Trebiz in 40, to Mons in 41, to the French frontier in 42, and to the Prussian frontier in 45, by which time 736 miles of road had been completed, amounting to 15,600,000 francs, or about 12,600l. per mile, exclusive of stations and carrying stock, which raised the cost to 16,500l. per mile. The Belgian lines open in 1836 were, from Ostend to Brussels, 86 miles; from Brussels to the French frontier at Quiervain, 60 miles; and from Mons to Nevy, 9 miles; from Brussels, by Malines and Liège to Herbechela, where it joins the Prussian line to Aix-la-Chapelle, 96 miles; and from Landen to Maastricht, also joining the line to Aix-la-Chapelle, 36 miles; from Bruges to Poperinge, joining a line to Calais, 59 miles; from Brussels to Mouscron, connected with the line from Lille to Paris, 73 miles; from Brussels to Antwerp, 26 miles; from Ghent, through Bruges, 41 miles; from Ostend to Antwerp, 31 miles; from Brussels to Ypres, 66 miles; from the Aix-la-Chapelle line, 85 miles; from Brussels to Erquelinnes, the direct Paris line, 66 miles; from Brussels to Namur, by Braine-le-Comte and Charleroi, 68 miles; from Louvain to Charleroi; by Ypres, 41 miles; from Brussels to Namur, 39 miles; from Manage to Ypres, 25 miles; from Ypres to Mons, 16 miles; a total of 890 miles. The Great Luxembourgu line, of which only parts are completed, is to join the French railways at Metz, and then connect Belgium with the Holy Roman Empire. Bruges, Ypres, and Ostend, only open as far as Namur, though the works are nearly completed as far as Arlon. The Great Luxembourg line, when finished, will form an important link in the chain of communications from England to the centre and south-east of Europe.

The portion of this railway system near Liège required very heavy works; but the average character has been easier
than of English railways. One great cause for this has been, that Belgian railways cross common roads on a level much more frequently than those of France, and which many bridges and viaducts have been rendered unnecessary. Very few accidents seem to have resulted from this plan, partly because the speed of Belgian railways is less than that of English. With the addition of a few miles of branches, the total length of the Government railways is about 350 miles; these, down to 1845, had cost 6,359,611l., including all expenses and an efficient working stock, or about 18,000l. per mile. A more extended plan was for several years before other Belgian lines of railway have been planned and carried out (so far as they are yet completed) by joint-stock companies, under certain concessions from the State. Among these are the Namur and Liège, about 66 miles of main line, the Sambre and Meuse, 46 miles together; the West Flanders, 96 miles, to accommodate the province of that name; and probably one or two others. A glance at a map of Europe will show that the Belgian main line from Ostend to Liège forms part of the trunk route from London to Paris through the Rhine valley—the railway-bridge shall have been built by the Prussian Government across the Rhine at Cologne, this route will become still more important. From the circumstance here mentioned, the Belgian railways have a very important and international character.

The northern neighbours of Belgium, the Dutch, have hitherto been very modest in their railway enterprises. The principal towns of Holland happen to be packed together in a tolerably small space, and the deeper waters and the Zuyder Zee; and a railway connection between them has thus been easily established. From Rotterdam to the Hague; from The Hague to Leyden and Haarlem; from Haarlem to Amsterdam; thence to Utrecht and Arnhem; and from Rotterdam to Utrecht, are branches of a belt road in intimate communication. There are however but two railways that cross the frontier, one from Amsterdam by Rotterdam and Dordrecht, crossing the Maas by steamer from Dordrecht to Moerdijk, and by Breda to Antwerp; and from Amsterdam by Arnhem to Emmerich in the Prussian states, and thence to Cologne.

France allowed herself to be anticipated by Belgium in the adoption of the railway system. While the lines were being slowly opened from Malines as the eastern towns were doing nothing but watching hesitatingly the result of English enterprise. While this hesitation on the part of the Government yet continued, a joint-stock company was quietly formed in 1832 for the building of a little line from Paris to St. Germain; the necessary powers were obtained in 1836, and the line was finished and opened in 1837. In this last-named year a commission was appointed to suggest a plan for a system of railways; the commission made a report in 1838; but as the Government and the Chamber of Deputies could not agree whether the railways should be national property or joint-stock private property, the plan fell to the ground altogether. Two companies, however, came forward and offered to construct railways with their own capital—from Paris to Orleans and from Paris to Rennes—on certain favourable concessions being made to them by the Government. These lines were formed, under many financial difficulties, and were at length opened, in 1838 and 1839. The results of the whole system of French railways was matured. The system comprised seven trunk lines—the first directed upon the Belgian frontier; the second, upon one or more of the ports; the third, upon the ocean, by one or more of the western ports, the fourth, upon the Spanish frontier, by Bayonne; the fifth, upon the Spanish frontier, by Perpignan, passing through the centre of France; the sixth, upon the Mediterranean, by Marseilles and the seventh, upon the Rhine, by Nancy and Strasbourg. As a further addition to the existing lines of railways from Marseille—one to Toulouse and Bordeaux, and one to Lyon and the Rhine at Mulhouse. These were to be constructed at the expense of the State, of the department, and of a joint-stock companies, all contributing on certain prescribed terms. The law of 1836 has had to undergo many modifications, but the general outline of the Government plan has been adhered to.

In some cases, private enterprise has come to the aid of the Government in another way. Thus, two short lines of railway have been opened in France, from Arbois to Besançon, and from Orébro to Nora; the two not much exceeding 40 miles; but a prospectus has been issued relating to a Swedish company, whose operations will be sanctioned by the King, which will connect Stockholm with Göteborg, 350 miles in length, which will connect the Baltic with the German Ocean or North Sea. Norway, too, has made a beginning. An English company began the works on a line of railway from Christianshavn on the Hallsing-Sund, which is the shortest way to the coast; while Münster is in a lake connected with the extensive inland navigation of the eastern part of Norway.
sent this is only completed as far as Eidevold, a distance of 48 miles.

In the wide-spread region to which the general name of Germany is applied—extending as it does from the confines of Denmark in the north to those of Turkey in the south—from the spot where it meets the Rhine in the west, the construction of railways must necessarily be very unequally distributed, arising from the great diversities in population and commercial Industry. There is, however, coming into larger use the building of such lines as have been developed. Some of the railways have been constructed by the respective governments, and others by private companies. Nearly all the whole of those in the Austrian empire, in Bavaria, in Württemburg, in Hanover, in Brunswick, and in Hesse, have been constructed and the line extended by companies who in most cases have been redeemed or purchased by the state—so unwilling are most of the states to allow the control of locomotion to slip out of their hands. In Prussia, and in a few of the other states, the traffic has been abstained from any direct interference with the construction or working of the railways; it has rather lent a fostering hand to private companies, in cases where the traffic did not appear to be large enough to pay an adequate dividend on the outlay. In order to keep down the expenditure to a reasonable limit, all costly works are avoided unless absolutely necessary; hilly districts are traversed by steep inclines and numerous curves, instead of by costly tunnels, cuttings, viaducts, and embankments; inasmuch as a slower rate of speed is necessary in such countries as England renders such gradients and curves easily manageable.

Taking Germany in its widest sense, as including the Austrian empire as well as the various states north and west of it; there were completed and opened between 1841 and 1847 about 3930 miles, and by the end of 1849 about 4590 miles. At the last-named date there were also 800 miles more in progress of construction, and about 3100 miles either decided on or contemplated, but without having been begun. Of the 3930 miles completed and projected, about 8430 miles. Prussia, with the Rhine states, possesses the larger portion, forming a net-work connecting them with France, Belgium, Bavaria, Austria, and Russia, and they show a great superiority of commercial activity over that of the more widely extended empire of Austria with its dependencies. Berlin is now connected by railways with Dresden, Prague, Vienna, Cracow, and Warsaw, but of course much of the line is beyond her own dominions. The lines in Prussia, though numerous, are generally, from that district of the empire, not long in themselves, though forming links on far longer lines: the single exception is the line from Berlin to Danzig and Königsberg in East Prussia, 400 miles. Austria, on the contrary, has a few which run on at a great length, and are only beginning now to be opened, such as the railway from Vienna to Trieste, 363 miles; from Vienna to Ternava, 368 miles; and from Vienna to Dombra, 68 miles beyond Cracow, 326 miles. Vienna at present is only connected with the general German system by a line from the Danube to Trieste, opened the beginning of 1850, from Berlin to Vienna, 343 miles; with that from Berlin to Prague, 211 miles; with the line from Belgrade to Vienna, 74 in the 100. As the 3rd class fare is only about 2s. 6d. per mile, and the 1st class a fraction over 1s. 6d., the average fares paid by the whole of the passengers is within 1d. per mile.

In the vast Russian empire, the first attempt to obtain railways was made by offering great advantages to any capitalists who would establish companies for this purpose; they were to have a gratuitions grant of all the land necessary, and all the timber and raw material which they might find necessary, the state to take away all tolls, and also to guarantee a stock free of duty; they were guaranteed by the Emperor a minimum dividend of four per cent. on their capital; and the great land-owners offered the use of their rents in consideration of the railway. The most important of these railways is that from St. Petersburg to Moscow, of 400 miles in length. The next in importance, in so far as it will connect Russia with central Europe, is the St. Petersburg and Warsaw, about 680 miles. A good railway, worked by horses, about 100 miles in length, has been formed to connect the Don with the Volga. There is a railway from St. Petersburg through a place near it called Tzarasko-soleo to Louga, about 84 miles. This is a part of the Warsaw line. Tzarasko-soleo has a royal residence, and between it and St. Petersburg there is a busy traffic, somewhat akin to that of our Greenwich railway, or to the Varesilles railway near Paris. Southern Russia is to have a railway from Odessa to Kief, to be continued possibly, at some future time, to Moscow, and thus to form a connecting line from Berlin via Stettin and Gumbinnen to the Black Sea. There are also lines planned from St. Petersburg to Cronstadt, and St. Petersburg to Baltischport in Estonia. The railway from Warsaw to Cracow is open, as well as the line from Minsk to Moscow; but in the other districts mentioned above, the works, so far as commenced at all, are proceeding slowly.

Of the countries lying south of the Alps, and west of the Pyrenees, little can yet be expected in respect to railway construction. Italy, with the large extent of her empire, France, Switzerland, and Austria, and Switzerland itself being surrounded by the Alps. Nevertheless Switzerland has not been inactive to the subject. There are now open lines from Basel to Lucerne, from Basel to Waldshutt, from Berne to Argen, from Herrenzüchsee to Zürich, from Zürich to Davos, from Zürich to St. Johann, and thence to Geneva: lines are also open from Turin to Piemolo, 33 miles; from Turin to Cuneo, 55 miles; from Turin to Genoa, 103 miles; from Turin to Biella, 56 miles; from Novara, 60 miles; from Turin to Bologna, 56 miles; and from Alessandria to Arona, 30 miles. Lines from Genoa to Novara, 63 miles, with a branch of 8 miles to Vigevano. By reaching Milan, from whence this line is not far distant, a communication would be opened with Verona, Mantua, and Venice; and the completion of the line to Genoa, which involves expensive engineering difficulties, would open a communication with France by Lyon.

In Italy, distracted as it is by political disputes, and broken up into so many states, the progress of railway enterprises has been rather retarded. Nothing has been done towards establishing international railways from state to state; but each state, or at least three of them, have now short lines confined to their own territories. In Tuscany, there are lines from Leghorn to Pisa, Florence to Sienna, Pisa to Lucca, and Florence to Prato; and in Naples the lines extend from Naples to Capua, and from Naples to Caprasia; from Rome a line of 12 miles is open to Frascati, and some other works are in progress. In the Austrian empire, the construction of the line from Milan eastward by Treviglio and Brescia to Verona and Venice, 176 miles, with a branch to Mantua. This line also communicates northward by Monza with Cenontratta on the line of S. Giorgio, and thus is well known, is situated on a series of islands; and these islands are connected with the mainland by a viaduct of great magnitude: it is 15,000 feet long, and has 392 arches, the piers of which rest upon 80,000 larch piles, driven into the bed of the lagune or channel.
Spain and Portugal have always been much isolated from the rest of Europe by the formidable Pyrenean barrier; and, from various causes, they have been slow to adopt the canal and railway systems which have been so valuable to the rest of Europe. Now, however, a new era is beginning, for Madrid is connected with Albadete in Murcia, 174 miles, which is proposed to continue to Zaragoza and Alicante. The other lines are from Barcelona to Arentes del Mar; from Barcelona to Granellos; from Barcelona to Martorell; from Barcelona to Reus, approaching Santander on the French frontier; from Cadiz to Xeros (or Jerez) de la Frontera; and from Valencia to Alcudia; all of them short lines, the length of the longest, that from Barcelona to Alcudia, being only 54 miles. The first has but one railway, under 30 miles in length, from Lisbon to Vizartides.

The Mohammedan, imitating the European in so many things, is now imitating him in railway enterprise. The Port of Egypt, eager to do all that can be done for facilitating the overland route to India, is now having a railway constructed from Alexandria towards Cairo, to touch the Nile at a point which will get rid of the slow transit along the canal from Alexandria, and thence to extend to Cairo. The crossing of the desert itself to Suez, whether from Cairo or from some port in the Mediterranean, has been very simply accomplished for several years past; schemes for ship-canaís and for railways have been brought forward in considerable numbers in a region of great want, and there is not at the present time, so far as we are aware, any strong probability that either a canal or a railway over the Isthmus will be constructed.

In India itself much has been done, and much more is in progress. About 150 miles of railway have been opened for traffic, and 1100 are in progress, to connect it with Delhi. But the terminus at Delhi, in consequence of the recent rebellion in India, it now is said, to be changed, and that the railway is to be taken by Almasa to the Persian Gulf, where is to be made the capital of northern-western India. From Bombay lines are to run to Mizapor, where it will join the Calcutta line to Delhi, to Madras, and to Ahmedabad; on the first 40 miles, and on the second 71 miles, have been opened, but the line is in progress on both; and, on the other lines, on the two lines; on the third nothing is opened, but the earth-works are completed from Surat to Ahmedabad, 150 miles. From Madras a line is laid out to the western coast of the peninsula, of which 90 miles are open, and 300 are in progress; and from Madras to Bellary, 386 miles are in progress of construction. [Indian Empire, p. 320, S. 2.]

In the United States of America, as early as 1843, we have that the rails had been established for 1,676 miles, the railway constructed, belonging to 143 companies, an average of only 36 miles as the length of each railway. The railways were constructed, as in England, by joint-stock companies, and not by the State; and although each railway company was exclusively for local business, it nevertheless arose eight great trunk lines of communication, by junctions of various lines. American railways have been constructed very much more cheaply than those in England, partly because the legal and legislative expenses are extremely small, partly because the land is bought at a low price, partly because timber is very cheap, partly because no useless expenditure is bestowed upon splendid stations, and partly because the relatively low price of labor is not increased by the expense of capital or labor. The railways are worked with care.

The eight great arteries of communication were,—1st, parallel to the sea-coast, throughout the whole vast distance from New England to Florida; 2nd, east and west from Boston to Lake Erie; 3rd, New York to Lake Erie; 4th, Philadelphia to Lake Erie; 4th, Philadelphia to Pittsburg, over the Alleghany Mountains, and comprising a system of railways and canals; 6th, Baltimore to the Ohio; 7th, Charleston to Cincinnati, uniting the Atlantic with the Gulf; 8th, New York to St. Louis. All these routes were actually completed in 1843, but that suffi-
cient had been done to show that such routes would result from the united labors of many companies influenced pri-
marily by local motives. By 1849 the length in work had increased to 6500 miles. Although the total length inhabited and commercially active, were naturally those in which railways were formed earliest and in greatest number; but the system gradually extended to the vast agricultural districts of the west; inso much that by 1849 there were five short railways in the state of Mississippi, ten in Louisiana, and a few in Alabama, Illinois, Michigan, Indiana, and Ohio. Dr. Lardner describes the utter strangeness of the sights and sounds presented by this encroachment of civilisa-
tion on the wilds of the west, this conquest of the wilderness, over the forest and the prairie. "Traveling in the back woods of Mississippi, through native forests where, till within a few years, human foot never trod, through solitude the stillness of which was never broken even by the red man, I have often been struck with the oddity of the scene—of our way by an engine driven by an artisan from Liverpool, and whirled at the rate of twenty miles an hour by the highest re-
finements of the art of locomotion. It is not easy to describe the sight—Although we see the part of the deer start from its lair at the moment of the ponderous machine, and the appearance of the snake-like train which follows it."—Railway Economy.

Of the 6000 miles of railway at work in the United States in 1849, more than half were in New York, Pennsylvania, and the New England States. Of these, the most remarkable, perhaps, is that which traverses Pennsylvania from east to west, as part of the route from Philadelphia to Pittsburg. First there are 61 miles of rail from Philadelphia to Columbia on the Susquehanna. Then there are 172 miles of canal from Columbia to Holidaysburg, which bring the traveler to the eastern base of the Alleghany Mountains. Next is the Portage railway of 37 miles, from Holidaysburg on the Susquehanna to the Alleghany. Then, from Ocean to Lake Erie, this railway has to climb a height of 1398 feet, and then descend 1172 feet; the trains are drawn up to the summit level by stationary engines and ropes; different levels being reached, one by one, by the aid of separate engines and ropes. From Lake Erie the route is completed through thirteen tunnels, the longest of which is five miles, to Pittsburgh. This fourfold division of the route is not so troublesome as it would be in England; for by an ingenious contrivance, the canal-boats are made available for land travel, and connecting lines are made across the Alleghany Mountains. All the railways, whether main or branch, are in an extremely good state of repair. The Pennsylvania is the most celebrated, and is second in length only to our own. The New England lines are in a better state than those in our own country.

By about the middle of the year 1851, it was estimated that the railways in the United States were more than 10,000 miles in length, having cost about 67,000,000$, or about 12½ cents per mile. The total length of all the railways open was stated to be 11,600 miles, besides 11,200 in course of construction, making a total of little less than 33,000 miles. An estimate for 1853 gives 13,000 miles as the probable length in the early autumn of that year, and ten miles more than this by the end of the year. All these lines are worked for traffic. In 1854 there were 17,217 miles completed, and 19,582 miles in course of construction. Since that period there has been a large, and the chief lines undertaken have been in connection with those of Canada. In January 1857 there were open and in work 34,320 miles of railway in the United States, and a line of 40 miles in length from Aspinwall to Panama. Including Canada there were in January, 1858, 440 lines, but many of them form portions of larger railways.

The American railways have several advantages which, to our discredit, have not been introduced upon English lines. Whether the abandonment of all"classes" in railway carriages, the non-distinction into 1st, 2nd, and 3rd class—whether this be an advantage or not, each reader must deter-
mine for himself. We shall simply state, therefore, that each is the case in the United States, and that the passengers—though they have not all the cushioned luxuries of first-
class railway carriages, are more comfortable and more distant from each other than our second and third-class passengers. The following is the type of an American railway carriage. It is two or three times as long as a London omnibus, but much wider and higher; there are doors at each end, and a row of windows half way along; the seats are designed to be turned to end, wide enough for one person to walk; and on both sides of this passage are rows of seats, transverse to the length of the carriage, and each accommodating two persons. There are from fifteen to twenty of these seats on each side of the
avenue, thus affording accommodation for sixty or eighty persons in the carriage. The seats are cushioned; and their backs, consisting of a single padded board about six inches broad, are so supported that the passenger may at his pleasure turn them either way, so as to have either his face or his back to the engine, the carriage can be turned at each end of the carriage; and in winter there is a small stove in the middle, with a smoke-pipe projecting through the roof. Some of the carriages have a ladies' compartment at one end. If these very large and roomy carriages were set upon any sort of railroad, it would be impossible to work them over curves of any but very wide radius; the arrangement adopted is, however, one which renders them even more manageable than our shorter construction. The Hamilton and Windsor is the only railroad truck, on which it rests on a pivot; similar to the expedient by which the fore-wheels of an ordinary road-carriage sustain the perch. On a sharp curve, the front truck may be moving in one direction, and the hind truck in a direction a little inclined to it, while the body of the vehicle forms the chord of the arc or curve. These long-bodied carriages have much less dead weight per passenger than English railway carriages. In American towns, the locomotive depôts are always in the suburbs, but the passenger coaches, the carriages of the train, are being drawn from the suburbs to the centre by horses, along the level of the streets. It should be remembered, however, that in many cases they are laid down as single lines. We have described one of the road-carriages that has recently been introduced in the United States, to excavate tunnels through hard rock. So far as descriptions of it have yet reached this country, it appears as if it would be a very valuable engineering aid. The machine works horizontally, and a rapid revolving tool bores a hole horizontally in the rock, a few inches in diameter. An enormous vertical wheel, equal in diameter to the intended section of the tunnel, has cutters or tools projecting horizontally from its face. At night there is a good lamp at the center of the rock, concentric with the hole first bored. The central hole is then charged with gunpowder, and a blast loosens and shatters the huge mass of rock between the hole and the groove. If, as is alleged, this machine will tunnel ten feet per day, it will greatly expedite railroad works, and cheapen them also.
